As described above, the ores are oxidized, so that smelting must be resorted to, and as the gangue consists principally of limestone and ferruginous material they make desirable products for smelting. There is an independent smelter at Deming, the only lead-silver plant in the territory. This enterprise purchases all kinds of lead ore on the most liberal terms, thereby infusing new life into the mining districts of New Mexico and Arizona. Here a 75-ton blast-furnace is in operation, but plans are now under way to increase its capacity by another unit, making it 150 tons, at the same time installing a small copper stack. Situated as it is on three important lines of railroads, the Southern Pacific, Santa Fé, and El Paso & Southwestern, its position is excellent. Fuel-cost is low, the plant being operated by Hornsby-Akroid crude oil engines, the oil costing 4.8c. per gallon, so the actual consumption per horsepower-hour is one pint. The plant has now been in operation three years, and has demonstrated its efficiency. It offers nothing new metallurgically, but the following data on the cost of supplies delivered at the works, may be of interest:

Coke, \$7.10 per ton; coal, \$5.25; wood, \$4.50; iron ore assaying 74% FeO, \$2.75; lime, \$1.50. Labor is cheap and efficient, foremen and engineers receiving \$4, dippers and feeders \$3, laborers \$1.25, pot and charge wheelers \$1.75, 12 hours constituting a day's work.

It is stated that the building of a large new electric power station in Lapland is shortly to be taken in hand. Either the Norr or Söderland falls will be used, and it is proposed to erect the power-station close to the Bräunland railway station, and within about 10 miles of the sea. The power available is estimated at 88,000 horse-power.

MINING AND METALLURGICAL PATENTS.

TRAMWAY LOADING DEVICE.—No. 910,499. Charles A. Case, New York.

No. 910,499.

No. 910,708.

The combination of an aerial tramway, a bucket propelled by a hauling rope of said tramway, a loading hopper supported on tracks adjacent to said tramway, a shaft that can oscillate about and move along its axial line supported on the loading hopper, an arm extending from said shaft, a roller journaled on the bucket in the path of said arm, a second arm extending from said shaft, a wedge located in the path of the second arm to engage therewith and thereby disengage the first arm and the roller on the bucket.

ELECTRIC HOIST.—No. 910,708. William O. Duntley, Chicago, Illinois.

In a device of the character described, a plurality of winding drums, a driving shaft actuating said drums, a motor casing, a plurality of motor armatures, a field magnet common to said armatures, transmission gearing for said armatures, an auxiliary shaft secured to said motor casing, a plurality of contacts mounted on said auxiliary shaft, a casing for said contacts, a trip arm adapted to shift said contacts, and means to lock said contacts in shifted position.

EXCAVATING APPARATUS.—No. 910,055. Dayton H. Gilson, Rushville, Indiana.

In an excavating apparatus, the combination with a supporting frame, and a scoop pivotally connected at its forward open end portion to said frame, of a depending latch pivotally connected to said frame, and a catch situated at the rear end of said scoop to be engaged by said latch to support the end of said scoop, a ball adjustably secured to said scoop and adapted to project at its forward end, beyond the open end portion of said scoop, a hauling rope connected to the forward end of said ball, whereby, when the scoop is unlatched to depend from its pivotal centre, said hauling

rope is operated to swing said scoop into position to be engaged by said latching means.

OSCILLATING SCREEN FOR ORE AND OTHER MATERIALS.—No. 911,113. Albion B. Colcord, Kokomo, Colorado.

In an oscillating screen, a pair of angularly disposed screens, which abut at their upper ends, a shaft to which said screens are attached, an adjustable counter-weight attached to said shaft and arranged to hold said screens in material receiving and screening position until the load of oversize material on said screen outweighs said counter-weight, said shaft and its counter-weight and said screens being arranged to oscillate a predetermined distance in alternate order from an operative ore receiving and screening position to an oversize discharging position, means including a hopper for flowing material over said screens in alternate order at each end of the oscillating movement of said screens, means for collecting the screenings product of said screens, means for leading the oversize product of said screens from them and collecting it together, means including piping for flowing jets of water against the under side of said screens in alternate order when in their oversize discharging position, and means including piping for flowing a supply of water into the oversize material after its discharge from said screens.

APPARATUS FOR CONCENTRATING ORES.—No. 911,077. Walter M. Sanders, Marion, Kentucky.

Apparatus for concentrating ore by flotation, comprising a tank having means for introducing ore and solution below the normal liquid surface, a central discharge gate for tailings, a substantially central overflow for concentrate, and a mechanical agitator constructed to impart a whirling motion to the liquid in the tank, to agitate the ore, and to transfer the tailings to said central discharge gate, substantially as described.

AMMONIA-CYANIDE PROCESS OF TREATING ORES CONTAINING PRECIOUS METALS.—No. 911,254. David Mosher, San Francisco, California.

The improvement in treating ores and tailings containing gold and silver, which consists in extracting the precious metals with a solution of ammonia and an alkaline earth-metal cyanide.

The improvement in treating copper, nickel, zinc, and cobalt ores and tailings with gold and silver values, which consists in simultaneously extracting all the metals with a solution of ammonia and an alkaline earth-metal cyanide.

Cameron Surface Condenser.

This apparatus is especially recommended for locations where the water supply for condensation is salt or unfit for boiler-feed, and where it is desired to save the condensed steam for that purpose. It will readily maintain a vacuum of 26 in. referred to a 30-in. barometer when supplied with sufficient cooling water.

The condenser is mounted on top of a direct-acting combined air and circulating pump, the three cylinders of which are in a straight line; the steam-cylinder in the centre and the air and water cylinders at each end. By this arrangement a very smooth and steady running pump is ensured, as the regulating action of the water-pump equalizes the irregular lead on the air-pump.

The water-chamber of the condenser rests directly on top of the water-cylinder and the circulating water passes upward from the water-cylinder and through the lower bank of tubes, returning through the upper bank and out at the highest point of the water-chamber. The arrangement is such that no air can lodge in the condenser-tubes and impair

their efficiency. Exhaust steam entering the top of the condenser near the circulating water outlet, spreads along the entire length of the condenser before passing on its course down through the tubes where it is condensed, and finds its way by gravity to the air-pump as condensed water, air, and non-condensable vapors.

The condenser shell, water-chamber, and covers, are cast-iron. The tubes are seamless drawn brass, and are secured at each end into muntz-metal tube plates by means of brass screw glands packed with corset-lace packing. The tubes are free to expand and contract, but are held from getting out of place endwise by a shoulder in the screw-glands. Where the tubes are long they rest in a support-plate placed midway in their length. In all cases they are relieved from any impact of incoming steam by a baffle-plate placed opposite the exhaust-steam inlet. The condenser can be opened up and inspected without disconnecting any of the pipe connections.

The steam-cylinder is of the well known Cameron type, with no outside valve-gear, and makes its full stroke every time. The steam-cylinder heads are removable without disconnecting any of the other parts. Both pump-cylinders are brass lined and are fitted with brass pistons arranged for fibrous packing. The piston-rods are of Tobin bronze and separate at the steam piston. The valve system in both air and water cylinders is of the usual Cameron arrangement. By removing the cover at each end of the cylinder every valve is exposed to view. Each valve-stem holds two valves with their springs one above the other so that by simply unscrewing one plug and pulling out the stem both are released. The air and water cylinders are in the most accessible position for inspection and repairs, and the air piston and valves are submerged at all times.

The A. S. Cameron Steam Pump Works are prepared to build all sizes of surface condensers up to 1500 hp., and can furnish condenser shells of sheet steel or copper where lightness is a factor, or pump ends of all brass if desired. Where there is not sufficient head room, the condenser may be placed alongside the pump, but in all cases it should be high enough for the condensed water to flow by gravity to the air-pump.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the **MINING AND SCIENTIFIC PRESS**.

BOLETIN DEL CUERPO DE INGENIEROS DE MINAS DEL PERU. No. 67. Issued by the Ministerio de Fomento, Lima.

ANNUAL REPORT OF THE MINING INDUSTRY OF IDAHO FOR 1908. By F. Cushing Moore, State Inspector of Mines.

THE GUADALUPIAN FAUNA. By George H. Girty. Professional Paper No. 58 of the United States Geological Survey.

WESTERN ELECTRICAL AND GAS DIRECTORY. Published by the Blanchfield Publishing Co., San Francisco. Price \$10.

This volume contains a list of all the electrical, gas, railway, and kindred companies operating in the States of Arizona, California, Nevada, Oregon, and Washington. It also contains a list of the contractors and dealers in each city of the States named. It should prove a valuable handbook to anyone interested in the electric or gas industries.

Commercial Paragraphs.

THE HERCULES GOLD MINING Co. of South Dakota has ordered Butters filters for its mill, which will be erected by Allis-Chalmers Company.

THE PACIFIC TANK Co. and the NATIONAL WOOD PIPE Co. advise us that in order to handle their increase of business in the North, they have opened a new office at 210 Wells-Fargo Bdg., Portland, Oregon.

THE BRIDGEMAN & BASCOM ROPE Co., St. Louis, Missouri, announces that the Western Equipment Co., 72 Fremont street, San Francisco, will in the future carry a large stock of 'Yellow Strand' wire rope, drilling cables, and sand lines.

WARREN WOOD, of the WOOD DRILL WORKS, Paterson, New Jersey, and ROBERT J. WOOD, manager of the Chicago branch, will leave the United States on February 19 for a three weeks visit to the Panama Canal zone for the purpose of inspecting the work being done by Wood rock drills, and upon their return the Wood Drill Works will publish a booklet containing valuable cost data and comparisons, with some interesting views along the canal.

Catalogues Received.

THE EUREKA DRILL STEEL Co., Denver, is distributing a circular which presents some conclusive arguments in favor of Lug steel for drills.

THE DEAN BROS. STEAM PUMP WORKS, Indianapolis, Indiana, has published, under date of January 1909 its catalogue No. 74 on condensing machinery.

THE INDUSTRIAL INSTRUMENT Co., Foxboro, Massachusetts, has lately published its Bulletin No. 16, describing its revolution counters, tachometers, and tachographs.

THE C. O. BARTLETT & SNOW Co., Cleveland, Ohio, is distributing its catalogue No. 28 illustrating and describing steamship fuel lighters, and coal and ash handling machinery.

THE DENVER FIRE CLAY Co., Denver, has lately issued two bulletins: one on muffle furnaces for coal, wood, coke, and oil; and one on Case melting furnaces for gasoline, gas, or oil.

THE WESTERN LUBRICATING VALVE Co., Denver, has recently published its catalogue No. 2, which is an attractively printed and illustrated pamphlet describing the Western lubricating valve and its advantages for use on rock-drills.

THE CYCLONE DRILL Co., Orrville, Ohio, has lately published its catalogue B-20, which illustrates and describes blast-hole machines of the rod and cable types, the traction machine, blast-hole loaders, and sounding and boring outfits.

THE HENDRIE & BOLTHOFF MFG. & SUPPLY Co., Denver, has issued under date of February 1 an odd stock sheet. Certain articles, that are either odd stock or second hand, are listed at a net selling price, which should be an advantage to one needing such machinery on short notice.

EDITORIAL.

ON MAY 7 the American Electrochemical Society will meet in annual convention at Niagara Falls. By reason of the unusual attractions, scenic and industrial, of the place of meeting, there should be a large attendance. Mr. Edward G. Acheson is president.

CONDITIONS of travel vary so much and have so important a bearing upon the work of the mining engineer that we hope the article on 'Travel in Colombia' will prove of service to the mining profession. It is written by one who knows South America well and is desirous of helping the investigators of mineral wealth attracted by the recent development of the country.

THAT is sensible comment which comes from London, criticizing the sudden leap in the market price of shares in Lake View Consols mine, just because the workings on the 1900-foot level had penetrated a streak of high-grade ore. It takes more than one swallow to make a summer, more than one glittering pocket in a mine to send a stream of golden bars to bank. The Lake View sequel is that an expansion of over a million dollars in the market valuation of the stock was occasioned by \$250 worth of ore.

A NECESSARY aid to the growth of industry, be it mining or any other, is easy, prompt, and inexpensive means of communication. Our relations with South America have been sadly hampered by inadequate mail facilities. The ship-subsidy bill, which passed the Senate the other day, was intended to promote closer communication with South America and Australia. This was killed in the House, but it is hoped that the new Congress will not fail to meet the demand of the people for a widening field of activity. In mining and commerce Latin America offers larger opportunity for our enterprise than any other part of the world.

THE National Good Roads Association will hold its annual convention at Baltimore next month. The influence of the Association is awakening the interest of legislators throughout the country in a subject that had fallen into neglect by reason of too great concentration of attention upon the railroad as the chief means of communication. But the railroads find their local business expanding in proportion to the improvement of the highways, and have become earnest abettors of the propaganda which the National Good Roads Association is making. With good roads and the automobile, the 'back country' districts will at least not be backward, but will be opened to the advantages and comforts of

civilization. This is a matter that concerns the miner and the farmer and all citizens, rural and urban. The headquarters of the Association are in the Opera House Building, Chicago.

CONFIRMATION of churn-drill sampling by shafts in the testing of placers, as insisted on by Mr. W. E. Thorne in his article published in this issue, is a point that will appeal forcibly to every man who has had experience in gravel-mining. Mr. Thorne declares that no ground is proved conclusively until some shafts have been sunk, and these should follow drill-holes, in order that, if discrepancies be found, the causes may at the same time be determined. Thus a means for interpretation of drill-results throughout a large area is supplied. The article is a sound statement of correct practice by one who knows.

NEW ZEALAND was the country in which gold-dredging practice was developed to success, and although no longer a leader in this branch of mining, it is interesting to note that 34 dredges are at work in the South Island; these produce about 1000 ounces of gold per week or a million dollars per year. The maximum production from this source was in 1905, when over 3000 ounces were extracted in one week, but even this when shared among 75 dredges does not represent mining on a large scale. The Yuba Consolidated, at Marysville, California, wins \$1,250,000 profit from about \$1,650,000 gross output of gold annually, and accomplishes this with 12 dredges. That is something like mining.

DITCHES constitute an integral part of mining operations. The making of a ditch at a minimum cost for a maximum efficiency is a pretty bit of engineering, and therefore the article by Mr. Douglas Waterman will be welcomed. Those who read the article will agree with us that he has made a notable contribution to technical literature. Such practical details tied by scientific principles are of immediate value to the operators and superintendents of mines. We hope other men versed in the subject will contribute further data. While in Alaska recently we were given the following figures concerning cost of maintenance in the Rampart district: the ditches are $2\frac{3}{4}$ to $4\frac{1}{2}$ miles long, the cost of maintaining them in serviceable condition ranged from \$468 to \$2250 per mile per season or \$24 to \$74 per miner's inch of water. These are high costs, due to the peculiar regional conditions described in recent articles in this journal. Of course, the biggest undertaking of this kind in the North is the Yukon ditch, which will come into use during the approaching season.

NOT LONG ago *The Evening Post* printed some doggerel making fun of the tariff hearings on zinc. In course of time these verses reached Great Britain, and the President of the Board of Trade, Mr. Winston Churchill, in a speech at Nottingham stated that he had received an official report in the course of which it was said that "the people in Kansas and Missouri who thought their interests

would be affected by the tariff alterations on zinc ore, were singing in chapels a hymn, the refrain of which was:

So now we humbly pray that we
Be saved from ruin's brink;
We will accept whate'er must be,
But Lord remember zinc."

These were the jesting verses published by *The Evening Post*. The story reminds one of the three crows and the ensuing exaggeration.

MR. TELLER complained in the Senate the other day that the plans for the construction of the Panama Canal are changed every six months, to which Mr. Kittridge added that the proposed site for the Gatún dam had been shifted eleven times. The criticism conveys an unjust impression: it assumes that the engineers should have made a thorough study of the situation before excavation was started. Beyond doubt such a preliminary would have been most proper, and Congress might have appropriated money years ago for that purpose, but whenever an examining commission was appointed it was sent to bring data in a hurry to promote action on some treaty or bill to rush the business through. The behavior of Congress in regard to the Panama Canal reminds us of the common habit of mining companies, which want a mill before the mine is proved, and erect expensive head-works before development has shown where to place the permanent shaft. Hence the subsequent history of the enterprise, if it end not in a crash, is one of eternal change and everlasting assessment. Such a policy lends no more cheerfulness to the directors' meetings than similar congressional errors have contributed to the crestfallen committeemen who have to provide for the absorbent Isthmian enterprise. It is the part of wisdom to get ready first; it costs more to get ready afterward. It is not the engineers who are to blame for making changes in the light of better understanding of conditions; it is the gentlemen at Washington who sent out junketing expeditions instead of authorizing the long and costly tests needful for elaboration of plans before commencing work. Now we must blunder along to the end, no matter how it swell the budget. The ultimate benefit will justify the cost.

Theodore Roosevelt.

This week has witnessed the inauguration of another President of the United States. The event is remarkable more because of the retirement of Mr. Roosevelt than for the incoming of Mr. Taft, for the latter has yet to make his mark as chief executive while the former steps down after nearly eight years of extraordinary activity. Before pronouncing an epitaph on his administration let us see how the alien world regards his accomplishment. Unquestionably in Europe the influence of Theodore Roosevelt upon the development of American life is appraised more highly than in his own country. Nor is this surprising; to those who are near, the smoke of battle obscures the commander; the noise of approval and of disapproval drowns the accents of the

speaker. Most of us are partisans, not spectators. Therefore, it is well to listen to the opinions of those who, by virtue of geographical and mental detachment, can more nearly anticipate the cool verdict of posterity. To them the ex-President is a great and useful man, epitomising 'qualities distinctively American. The fuss and fury of impulsive speaking, the personal encounter with political opponents, the wire-pulling of machine politics, the almost tiresome versatility of the man, and the cock-sureness of the strenuous reformer are not impressed upon the consciousness of the student of modern history resident at Vienna or London. From these points of vantage Theodore Roosevelt looms to heroic size, he is regarded as a fearless fighter against corruption, as a tremendous power for righteous dealing, as an up-lifter of national ideals. And shall we fall behind the European in admiration of this remarkable American? Has he not fought our battle, is he not the strongest leader of reform and the most powerful foe of special privilege; is he not the one man who has been able to check the predatory captains of industry who seemed but recently on the verge of controlling our political life? The answer is obvious; yet we are reminded of the definition of a friend as "the man whom you know and still like." So we honor Mr. Roosevelt while seeing much to deprecate. His faults, however, are distinctively American and therefore lovable to his own people. The American likes to "do things" regardless of precedent, he possesses an impatience of restraint that gradates easily into disregard of law; this tendency the ex-President has repeatedly expressed by word and deed; he will go down in history as the executive who cut through red tape with cheerful confidence; and many consider that he performed useful service in so doing, for the United States is burdened with a written constitution which is so difficult to adapt to modern problems that it has required almost a revolutionary to make changes seemingly necessary. From this difficulty Mr. Taft may find escape in a way more pleasing to a lawyer than the disregard of precedent shown by his predecessor. New interpretations of the constitutional provisions may be found by the legal mind of a President who was intended for a judge of the Supreme Court. Nor is analogy lacking—and a respectable one too: the New Testament during the centuries has undergone such diverse interpretation as to supply the fundamental tenets for countless sects; it may be that Mr. Taft will so interpret the American political testament as to achieve Mr. Roosevelt's purpose in a more orthodox manner. Something had to be done. Mr. Roosevelt in his seven or eight years of power has accomplished what otherwise might have required the time of a generation. And this is what the mass of the American people like, having made up their minds that something had to be done to check the corruption that was sapping the foundations of industrial civilization from New York to San Francisco, and from Chicago to New Orleans. He made blunders, but they are deemed well meant; he proved himself a deft politician, but the wires on

which he played were occasionally too evident; he was boisterous in his praise of friends as in his condemnation of enemies, but that was considered his breezy way. The public at large took him at his word and liked to see human frailties that brought him closer to themselves. "He made good." For ourselves, we are glad to have seen these years of Rooseveltian disturbance; we have been amused at the hissing of the votaries of the ticker whose speculative debauches he interrupted; we have appreciated the meaning of the hate expressed by the "malefactors of great wealth" as being a tribute to his sincerity; we have noted the applause of the men who hope for the development of representative government and the retention of the American idea of equality of opportunity to all. In stepping down from his high office to become the first citizen of the United States, Mr. Roosevelt takes with him the grateful appreciation of millions and the hope that he may be spared to a long life of great usefulness.

Copper.

The hope has been expressed that the lower prices for steel, due to the recession from an artificial position, would stimulate the buying of copper; it being held that the abnormal cost of steel had hindered the industrial development which creates a demand for copper. That seems logical, but it will not supervene until the steel manufacturers leave an open market; at present copper is unprotected either by tariff or trust; steel is buttressed by both. Meanwhile copper at 12½ cents is approaching that danger line at which the profits of many mining companies will vanish. In general terms the American copper output of 3,500,000 pounds per day is produced at a cost of slightly over 10 cents per pound, but many mines produce the metal at 11 or 12 cents per pound, and these are endangered. To any director or shareholder believing in a better market for copper, it must seem suicidal to consume the ore reserves of his mine in the effort to make a niggardly profit, such as the Greene Cananea with a cost of 10½ cents or the Shannon with costs at 12 cents per pound. Yet some of the mines that produce copper on the smallest margin of profit, such as the Anaconda and other Amalgamated properties in Montana, are among the biggest factors in overloading a glutted market. Of course, the Calumet & Hecla people can afford to refuse to join in any 'combine' in possible violation of law, and they can assume a position as painfully independent as it is painfully moral to the Amalgamated directors, simply because the Calumet & Hecla produces copper at 8½ cents and can earn \$37 per share even with copper at 13 cents. If the mines operating on the ragged edge will persist in flooding the market with metal the production of which will profit them but little while it spoils the sale of that produced by other mines, the price must continue low, until an automatic rise follows in the wake of industrial expansion. The copper-selling agencies occasionally permit so-called authoritative statements to be published in the daily press with a view to bolstering public confidence and

persuading consumers of the metal that a rise is imminent, but these efforts are pathetically funny, they remind one of Mrs. Partington when she tried to sweep back the incoming tide with her broom. The Amalgamated people, particularly, have twice essayed to control the price in defiance of economic conditions and twice have they been hoisted by their own petard. To the onlooker the copper people are plainly at sea, drifting in a fog of misinformation. In the course of time the new statistical venture of the Producers Association may cast light through the gloom; in the meantime to the man with one eye it looks as if too much copper were being produced and too little sold, the consumer chuckling at the efforts of the producer to boost the price in the face of slackened demand. When a fire underground threatened to stop production in the Anaconda mine, the shares of other copper mines went *down*, although it is obvious that the misfortune of a big mine would cause a decrease in the output that was swamping the market. This is an example of the artificial conditions created by stock-market manipulation.

Railroad Rates.

The mining industry of the Rocky Mountain region and of the Pacific Coast is in a fair way to gain long needed relief if the decision just rendered by the Interstate Commerce Commission in favor of Spokane be applied as a ruling principle. Familiarity with discriminative freight rates has not destroyed the sense of impropriety that a man experiences in seeing his car of mining supplies go bumping past his station to San Francisco or Los Angeles, to return a week later with the added local rate from the terminal city to the final destination of the shipment. The long-haul anomaly is opposed to an innate feeling for justice. The economic reasons are explicable, that is, the railroads can make out a case, but under cover of the principle as put in practice discriminations are made that work severe hardship. The case of Spokane has for years been prominent as an example of the flagrant misuse of the opportunities for favoring certain shippers presented by place-discrimination in fixing rates. The instance of the wooden pipe industry is well known in the history of the rate-struggle. Spokane had developed that business to large proportions. A rival in Seattle made a bargain with the railroad which enabled him to lay down pipe in Spokane nearly 60 per cent cheaper than it could locally be produced. It was shown that the Seattle firm, by reason of favoring rates, could even deliver pipe at Butte at the cost of manufacture in Spokane. Other examples of discrimination existed in the fixing of a rate per hundred pounds on iron pipe from Chicago common points to Spokane at \$1 while to Seattle the rate was 50 cents; on mining car-wheels the respective rates were \$1.26 and 85 cents; on wire and manufactures of wire \$2.35 and \$1.50. The average advantage enjoyed by Seattle over Spokane by reason of these preferential rates has been about 80 per cent.

The importance of the decision now rendered is that a principle long urged as a remedy against

unjust discriminations has been applied. It may seem to depart from the old common law idea, which recognizes that the burden of proof rests upon the plaintiff. Though the rates as fixed by the railroads are often offensive through their rank disregard of public right, they are not offenses in a legal sense. The railroad is an arm of the government by reason of the license that enables it to profit as a common carrier. As such it must demonstrate the necessity for its acts. This is the finding of the Interstate Commerce Commission. It issues a warning to the railroads in these words: "Water competition may justify a difference in carload minimums and in the right of combining different commodities at the carload rate, as well as the rate itself; but carriers should be prepared to justify such preference." The point is one of large significance. Possible water competition is not the same as actual rivalry. In proportion as parallelism between a rail and water-route is approached the magnitude of the time-factor disappears. This has been conspicuous in the influence of the Great Lakes in controlling rates, but the enormous loop around a continent which a ship must follow in proceeding from New York to San Francisco reduces active water competition to a minimum, for the time in transit for sailing ships averages about six months, and almost half that time is required by steamships. The method of the railroads has been to distribute the estimated earnings in accordance with the expected volume of traffic on the basis of competitive rates by water to Pacific ports, while the interior towns have been made to pay the difference.

The principle of protecting the seaport in its advantage as a distributing point within its own particular zone of commercial attraction, is not disturbed by the decision; it is only the enormous disproportion between the charges for the long and short hauls that the railroads must justify. In addition, the Commission materially advances the position of those who regard the railroads as existing primarily for the good of the general public. The fifth, seventh, and ninth findings in the decision declare in unequivocal terms that railroad earnings shall not be excessive, and that the public at large shall not be unduly taxed for the sake of distributing a surplus to stockholders. The recognition of the railroad as a public-utility enterprise is made more explicit by this notable document. The earnings of the Great Northern and the Northern Pacific railroads are declared to have been excessive in recent years. In consequence, the Commission has ordered a horizontal reduction in the rates to Spokane equivalent to about 16 $\frac{2}{3}$ per cent. If applied to other points as a general principle, it will work a revolution in rates from Eastern points, the benefit of which will be particularly felt in the mining regions of the West from Canada to Mexico. The Interstate Commerce Commission early last autumn smashed the absurd regulations that made it cheaper for a California miner to ship his stamp-mill from Chicago to Shanghai and back to San Francisco than to bill it in the rational way. Another step forward has been taken for the relief of the West.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

R. A. F. PENROSE is in British Guiana.

KARL EILERS was in San Francisco for a few days.

JOHN B. FARISH will be in San Francisco on March 9.

EDWIN HALL has been appointed State Geologist of Wyoming.

FRANK W. OLDFIELD is examining mines near Parral, Mexico.

EDGAR RICKARD left London on March 3, returning to San Francisco.

HENRY BOSSUAT is manager of the Dos Estrellas mine, at El Oro, Mexico.

E. F. YATES, lately at Rawhide, Nevada, is here on his way to Mexico.

RUEL C. WARRINER is now manager of the Crown Mines, in the Transvaal.

ROBERT LINTON was in San Francisco on his way to Portland, Oregon.

C. M. HAMSHAW, of New York, will return to Fairbanks, Alaska, in March.

RICHARD C. SHAW is examining mines near Mojave, for Los Angeles capitalists.

D. C. FESSENDEN has left Manhattan, Nevada, and is now at Riverside, California.

DOUGLAS WATERMAN has gone to Amador county, California, to examine mines.

S. H. BROCKUNIER has returned from Juneau, Alaska, to Wheeling, West Virginia.

PIERRE BOUERY is manager for the Lagrange Mining Co. at Weaverville, California.

E. P. MATHEWSON, of the International Smelting & Refining Co., is in Salt Lake City.

FRANK ANDERSON, of Salt Lake City, is engaged in professional work at Globe, Arizona.

A. V. THORNS has resigned as superintendent for F. G. Manley, near Hot Springs, Alaska.

ANGUS R. MACKAY, of Montreal, is manager of the Vulture mine, in Maricopa county, Arizona.

C. W. WHITLEY, manager for the A. S. & R. Co., at Salt Lake, has gone to Europe on a holiday.

S. E. BRETHERTON, metallurgical engineer, announces a removal to 311 Mills Bdg., San Francisco.

GEORGE Z. EDWARDS is manager for the Cannon Ball M. & M. Co., operating in Blaine county, Idaho.

W. SPENCER HUTCHINSON, of Boston, was in San Francisco on his return from the Vulture mine, Arizona.

HOWARD P. SAUNDERS, mechanical engineer, Salt Lake City, is making drawings for Fink smelting furnaces.

F. C. ROBERTS has resigned as manager of the Ventanas mine, Durango, and will engage in business in San Francisco.

EDGAR L. NEWHOUSE, vice-president in charge of smelting operations for the A. S. & R. Co., visited San Francisco this week.

HENRY C. BEELER, formerly State Geologist of Wyoming, has opened an office as mining engineer at 222 Boston Bdg., Denver.

J. PARKE CHANNING has been elected vice-president of the General Development Co., of which Adolph Lewisohn is president.

GEORGE E. DRISCOLL is mill superintendent for the New York and Honduras Rosario Mining Co., at San Juancito, Honduras.

J. N. HOWELL and J. W. KINGSBURY have become partners in engineering and geological work and have opened an office in Salt Lake City.

L. WEBSTER WICKES, formerly with the Gunn-Thompson Co., has opened an office in the Judge Bdg., Salt Lake City, to engage in mining engineering.

FRANK A. KEITH has resigned as manager for the Tonopah Mining Co., Nevada, and has opened an office in the First National Bank Bdg., San Francisco.

VANCE C. OSMONT, formerly consulting engineer to the Nevada Mining Reduction & Power Co., of Dayton, Nevada, has opened an office as a mining engineer in the Monadnock Bdg., San Francisco.

THOMAS COX, formerly at Ely, Nevada, will leave Cerro de Pasco, Peru, and is expected in San Francisco in June. He will join EDMUND JUESSEN, and the firm will have offices in San Francisco.

General Mining News.

ARIZONA.

MARICOPA COUNTY.

The Vulture Mines Co. has re-opened its mines at Vulture at the initiative of W. Spencer Hutchinson, of Boston, and Angus R. Mackay, of Montreal. Work began last September and has been pursued with the most gratifying results. The principal openings of new ground have been on the 350 and 450-ft. levels, where orebodies have been discovered of encouraging character. Ten of the 80 stamps have been repaired to serve as a test, and 85 to 87% of the gross value has been extracted by amalgamation, under the direction of Chauncey Wetmore. The cyanide annex has so far not been brought into use. Robert Johns is mine superintendent.

MOHAVE COUNTY.

W. S. Phillips, of Chicago, is reported to have made arrangements to build a 20-stamp mill in the Goldflat district; and W. De Lancy Granniss has come from New York to see about the development of a mine in the same region, making Kingman his temporary headquarters.—Three hundred tons of freight have been hauled from Chloride to the Colorado river, as part of the material for the dredge of the Colorado Dredging Co. It is expected to have the machine ready before the season of high water in the river.—O. F. Kuencer reports that he is opening up the 500-ft. level of the Golden Gem mine with conspicuous success. A delay in the arrangements for a water supply has been the only reason to prevent the starting of his mill.

PINAL COUNTY.

The American Boy mines, 7 miles from Casa Grande, have been closed down on account of water. H. V. Elliott, the superintendent, has ordered a pump, and is devoting the time until it comes to prospecting with a core-drill. The shaft is 252 ft. deep, and there are 300 ft. of drifts on the 200-ft. level. R. J. Wessell and J. R. Meyer, two of the directors, have lately been on the property.

YAVAPAI COUNTY.

The Territorial Geologist, William P. Blake, has written a paper on the Minerals of Arizona, showing their occurrence and association, with notes on their composition.—H. H. Keays, manager for the Bockariz Mining Co., states that the mill for treating the ore from the Gold Ring and Etta mines will be in running order within 10 days, and that the cyanide plant will be ready a few days later. The plant will have a daily capacity of 25 tons, and comprises amalgamation and concentration, with cyanidation of the tailing.—The Arizona Gold Lodes Co. holds title to the R. H. Burmeister property on Cherry creek, and is constructing a mill close to the mine shaft, under the direction of W. W. Elliott.

YUMA COUNTY.

Thomas H. Finnegan, of Bouse, Judge Stilwell and Charles McDonald, of Phoenix, are the owners of the Calcite Copper Co.'s mines, five miles from Vicksburg. They have a shaft 120 ft. deep at a contact between quartzite and porphyry, the first 80 ft. of which were sunk through calcite and iron sulphide carrying no valuable minerals. The remainder of the shaft, however, has been in copper sulphide, and has given cause to expect rich results with farther development.

CALIFORNIA.

INYO COUNTY.

The Inyo Mines Syndicate has purchased the old Tower mine, in the Yellow Jacket district, a few miles south of Benton, from the trustees of the late John F. Millner's estate, and intends to get the mine into productive condition. It has been worked at various times since 1876, producing much high-grade silver ore with a little gold, and the directors of the Syndicate, W. W. Watterson and W. Gillette Scott, expect to make use of the pumps, boilers, hoists, etc.,

already on the ground.—The Greenwater Copper Mines & Smelter Co. is essentially a holding company, possessing no ground of its own, but holds a controlling interest in the mines of the subsidiary enterprises. Its annual report for the year ending December 31 shows that it owns nearly all of the issued stock of the Greenwater & Death Valley Copper Co., of the United Greenwater Copper Co., and of the following companies: Governor Greenwater Copper Co., El Capitan Copper Mining Co., Iron Clad Greenwater Copper Co., and Eagle Mountain Water Co. Of its workings the Copper Queen shaft No. 2 has been the most promising, and work for the past year has been confined to this shaft, which has been sunk to the depth of 1098 ft. In addition to sinking this shaft, there have been run 886 ft. of drifts and cross-cuts. The mine operations at Greenwater are conducted under the management of John McGee, who was engaged to succeed Jerry Rourke, the former manager. The report shows a balance of \$138,130 cash in hand.—The Modock mine was worked a score of years ago for the Hearst and Haggin interests; last spring it was opened again by John W. Kelly, and more rich ore has been produced from it. Only high-grade ore, however, can be shipped, for it has to be brought 13 miles on burros to Darwin, before hauling the remaining 25 miles to the railroad at Keeler.

PLACER COUNTY.

A 250-ft. adit is being run to work a deep channel at the White Oak, near Forest Hill. Near the same place, at the Canothus, John Gavin is reported to have struck a rich body of gravel.

SHASTA COUNTY.

The Afterthought mines and smelter in Shasta county belonged to the Great Western Gold Co., and are situated at Ingot, 35 miles east of Redding, and on Platt creek 9 miles north of Redding. It appears that the Afterthought Copper Co., an Arizona corporation, has secured control of the mines and smelter and also the Liberty claim on the Shasta copper belt. The terms of purchase include the payment of \$1 and 8,000,000 shares of the capital stock by the new owners, the principal of whom are O. E. Adams and S. E. Bretherton.—The Delta Consolidated Gold Mines Co. has purchased the Trinity Consolidated gold and silver mines. This property comprises six claims with a 10-stamp mill, and is situated about 7 miles west of Delta. With the purchase of the Trinity, the Delta Consolidated has increased its holdings until it now controls approximately 1000 acres of mineral land in the heart of the district. Between 8000 and 9000 ft. of development have been done, and the Consolidated interests have opened up one-half of the entire development since the company became interested.

TUOLUMNE COUNTY.

(Special Correspondence).—The Porto Fino mine, in the northern suburbs of Tuolumne, is being unwatered to permit a thorough examination being made by prospective buyers.—The Gold Ship Gold Mining Co. is about to commence work at its gravel property in the vicinity of Groveland. W. J. Graham will be the superintendent.—At the Grant mine, three miles north of Italian Bar, and operated by Minnesota capitalists, a cross-cut is being driven to the vein. This was deemed necessary owing to the large quantity of water flowing into the shaft. The cross-cut will be 800 ft. long. Good-grade ore has been found while sinking the shaft.—A shoot of fine ore has been uncovered in the 1900-ft. adit at the Riverside mine, above Columbia. The orebody is 3 ft. wide and is rich in free gold, galena, and other sulphides. The mill was started up this week and is running night and day.—The mill at the Nervi mine, near Columbia, began stamping ore this week after a brief idleness. A new adit was recently started and is now 50 ft. long. During the recent severe storm an immense landslide occurred, the mill barely escaping destruction.—It is reported that a rich strike has been made in the Tarantula mine, at Jacksonville, which adjoins the well-known Eagle Shawmut. —Louis and Edward Mase: t Sonora,

are installing a Huntington mill at the Birney mine, on Bald Mtn., northeast of Sonora, for the purpose of milling the dumps on that and adjoining properties.—Work was commenced in earnest this week at the gravel mine on the Calder ranch by Divoll & Leaver, of Sonora. The property, which is situated in the vicinity of Confidence, and believed to be one of the most promising gravel mines in Tuolumne county today, has been equipped with all machinery necessary to conduct extensive operations in the most economical and workmanlike manner.—Operations are to be resumed at the Del Monte mine, in the Groveland district. For some time work will be almost exclusively confined to sinking a new shaft, which, according to present intentions, will be sunk at least 500 feet.

Tuolumne, February 26.

The Karnac Mining & Milling Co., an Eastern corporation, has obtained control of the Hancock quartz mine and what are known as the Mable mines in the Rosslyn district, about 5 miles northwest of Jamestown. According to agreement, the company must pay to the owners of the Hancock, Edward D. Leonard and wife, \$50 per month during the life of the bond, which will expire in January 1914. If the bond is taken up the full purchase price of \$25,000 must be paid before that date. The other claims taken over by the Karnac company have been held by A. S. J. Anderson for a number of years.—Hydraulic mining will soon begin at the Alta Sonora mine at Brown's flat. A dam has been constructed below the Alta Sonora, 380 ft. long, from plans furnished by the California Debris Commission.—J. M. Elmer, of the United Mines Corporation at Tuolumne, states that he was able to crush 100 tons of hard quartz with a 10-stamp battery and a Hardinge mill, in 24 hours.

YUBA COUNTY.

E. W. Tarr has purchased the old Blue Point gravel mine near Marysville. It was once owned by P. Campbell, who took out much gold, and still believes there is plenty left. Tarr has been taking prospective investors to view his property.

COLORADO.

CLEAR CREEK COUNTY.

The Georgetown quadrangle, an area comprising about 230 square miles in Clear Creek and Park counties, Colorado, is described by the Geological Survey in Professional Paper No. 63 by J. E. Spurr, G. H. Garrey, and S. H. Ball. The paper includes also a description of the Empire district, an adjacent area in Clear Creek county.

(Special Correspondence).—It is announced that during the present year the sum of \$100,000 will be expended by the Astor-Stewart M. & M. Co., operating the Sunburst, Astor, and Scepter mines on Democrat Mtn. It is intended to bring machine-drills into use in the various workings of the properties owned, the compressor plant having already been ordered. A raise is being made from the Scepter adit, and within the next two weeks the working force is to be increased. On the western side of the mountain a force of men has been put to work in cleaning out the Sunburst and Astor workings and everything is to be placed in condition for the extraction of the medium and low-grade ore exposed. No shipments will be started until the raise from the Scepter has been completed, at which time chutes will be put in, permitting of the tramming of all ore through the Scepter adit, the portal of which is situated on the Georgetown side of the hill. The aerial tramway running to the road leading into town is to be repaired at once for the delivery of the ores, reducing the present cost from \$5 to \$6 per ton to about 50¢. It is reported that this company will shortly start work upon the construction of a 100-ton concentrating plant. The grading has been completed, and as valuable water-rights are owned, the expense of completing the plant will be small in comparison to other mills that have been built in this district. M. J. Riley has been placed in charge of the work on the west side of the hill, while Ira Clapper will be in charge on the Georgetown side. S. D. Houseman, of Denver, is the man-

ager of the property.—E. W. Shepard, manager for the Paragon M. & T. Co., is employing a force of men in the driving of the Paragon adit, the portal of which is situated on Leavenworth Mtn., opposite Silver Plume. It is proposed to drive this adit at least one mile to intersect the mines of the district at depth. The Paragon Co. controls a big group of lode claims on that mountain and the first one will be reached within the next 100 ft. Shepard states that the directors of the enterprise contemplate building a power-plant in Georgetown during the coming summer.—The new 25-ton mill of the Honest John M. M. & T. Co., situated on Chicago creek, will be brought into commission during the coming week. Work on the aerial tramway is being rushed in order to have everything in readiness for the delivery of ore. This tramway will be 2774 ft. long, and will have a daily capacity of 100 tons, being operated by gravity. On the seventh level of the mine a strike of importance has just been made in the east drift. The streak measures from 10 to 16 in. wide and is worth \$72 per ton in gold, silver, and lead. The drift has now been extended 100 ft. and early next week machine-drills are to be brought into use to hasten development.—Mine operators and lessees at Idaho Springs are advocating the construction of a co-operative sampler. It is contended by many that the local sampler does not pay for the full value of the ore. In case a heavy percentage of zinc is contained, it is figured that by owning their own sampler the operators can protect themselves by separating the zinc when over 10% is contained. This would save \$1 per ton sampler charges and by shipping to an independent smelter another saving of \$1 per ton would be effected. Figures by many operators show that the miners of Clear Creek county are robbed of between \$100,000 and \$125,000 yearly from this one source. It is likely that a number of operators in Georgetown, Silver Plume, Empire, Lawson, and Dumont will assist and support the new enterprise.

Georgetown, February 27.

GILPIN COUNTY.

The Tucker mill in the Quartz valley district has been purchased from the Lyons-Kyle Mining Co. by William H. Hearne, for the Hearne Gold & Copper Mining Co., which also operates the Anchor group in Willis gulch. The Tucker mill has a daily capacity of 75 tons, and is equipped with 10 rapid-drop stamps, jigs, and Wilfley tables. H. Irving Jones, who is manager of the Anchor property, will also have charge of the mill.

OURAY COUNTY.

Snow storms have been continuous around Ouray. For some days the Camp Bird mill closed down for fear of the U. S. snowslide, as the slide-break which the company constructed was entirely buried.—Joseph H. Tumbach has taken first steps in opening the Pony Express mine in the Paquin district to the north of Ouray. It belongs to the Century Mining Co., and has been idle for the past ten years. There is a dump with about 70,000 tons of low-grade ore estimated to average \$11 per ton in gold, silver, lead, and copper. Should developments prove favorable a mill will be constructed.

SAN JUAN COUNTY.

The Hercules Consolidated Mining & Milling Co. had the shaft of its crusher break, necessitating a temporary shut-down at the mill. Charles Dale has more than 20 cars of concentrate now awaiting the lifting of the snow blockade so that they can be shipped to Durango.

TELLUR COUNTY.

The Morris Bros., leasing on the Morning Star claim of the Acacia company, on the eastern slope of Bull hill, have installed a gasoline hoist and are getting out ore. A two-car shipment is being prepared and will be loaded this week. The lessees are driving and stoping on a well defined vein on the 250-ft. level, with the coarse rock averaging \$20 and the screening \$30 per ton. Three large solution tanks and a commodious ore house and mill building have been erected below the dump at the Tornado mine on the southern slope

of Raven hill, by Dodge and associates, who hold a lease from the Elkton Consolidated Mining & Milling Co. The dump operators intend installing a tramway similar to the one in use at the Wild Horse and Anaconda mills.

IDAHO.

IDAHO COUNTY.

Mine owners in the Elk City district in central Idaho are already contracting for the freighting of machinery into that camp, and there is every indication there will be much activity this year. F. W. Bradley reports that thousands of tons of ore are blocked out in the Buster mine, while others are nearing the shipping point.

NEZ PERCE COUNTY.

The Peck Mining & Milling Co., operating at Peck, has showings of silver and copper ore running \$50 per ton. The

Surveys for this extension will be commenced as soon as the snow is off the ground. The extension into the Sunset country will be completed this year if possible and will start at the station of Beaver on the main line and give service to the Callahan, Nipsic, Idora, Tamarack & Chesapeake, and other properties in that region.—About 2 ft. of gray copper ore has been exposed in the upper workings of the Rainbow Mining company's property near Osburn. Work in the upper adit has been discontinued, and the management has set the men to continue the lower adit to drive about 500 ft. below the ore exposed above.—An important strike of ore has been made on the property of the Copper Age & Edison mine at Saltese. Samples of this ore taken from a 3-ft. pay-streak give an average return of 16% copper and about \$47 gold per ton. The strike was made at a depth of about 500 ft. and 900 ft. from the entry of the adit.—It is proposed to advertise the Coeur d'Alene country at the Alaska-Yukon-Pacific exposition by means of a model mine representing a section through one of the great mines of the district. The section will be equipped with cars carrying representative samples of the minerals found there. The whole model will be under a mining man who will explain all technicalities and endeavor to interest visitors in the mines of the Northwest.

The Moon Creek mine near Kellogg is owned by J. M. McLain, of Spokane, and his associates. Samples from the property show 37% lead and 22 oz. silver per ton. There is

The Coeur d'Alene, Idaho.

Hoist at the Trimountain Mine.

company owns 640 acres of well-timbered land and ample water-power. Considerable ore has been blocked out for shipment to the smelter at Ponderay.

SHOSHONE COUNTY.

(Special Correspondence).—Among the important developments of the past week in the Coeur d'Alene is a strike of 4 ft. of solid galena made on the 1450-ft. level of the Standard mine at Mace. The vein has not been cross-cut and the full extent of the orebody has not been ascertained. It is intended to continue the shaft to the 1600-ft. level and to commence drifting. The Standard mine is one of the properties of the Federal Mining & Smelting Co., and has paid out about \$8,000,000 in dividends. The reserve in sight is now greater than at any other time in the history of the company.—E. P. Spalding, vice-president and manager of the Idaho Northern railroad, has announced that extensions of the line will be ultimately carried to Spokane and through the coalfields of Alberta. During the coming summer it is expected that a 15-mile line will be constructed on the Little North Fork for the purpose of opening up the copper and timbered areas of that portion of the Coeur d'Alene. This line will also be connected with the smelter proposed to be erected by Portland capitalists at the mouth of the Little North Fork. It is this line that will ultimately be extended into Spokane, giving at the same time a short and economical route to the Panhandle smelter.

a flume 6800 ft. long with a head of 185 ft., also an electric dynamo for light and power.

MICHIGAN.

The improvement in the ore of the Trimountain mine, the lowest-grade producer of the Copper Range Co., has developed into a strike of exceptional richness. The improvement was first seen in No. 3 shaft on the fourteenth level, but is more noteworthy on the fifteenth.—The Cliff mine is diamond-drilling the Kearsarge formation on its land adjoining Ojibway on the north. The drill is running in bedrock and is expected to encounter the lode before the end of the month. The annual report of the Mass mine will show a cost of mining and shipping rock to the mill of \$1.35 per ton, probably the lowest cost in the Lake district.

MONTANA.

MADISON COUNTY.

Conrey Placer Mining Co., operating dredges at the mouth of Alder gulch near Virginia City, distributed a bonus amounting to \$5000 to its workmen the last pay day. The amounts ranged from \$150 to \$5, according to length of service. The company is controlled by New England capital, with offices in Boston.

SILVER BOW COUNTY.

The shaft of the Butte & Superior Co. has reached a depth of 1400 ft., where a large station is being cut. Some-

copper ore has been found on the 1200-ft. level, and gives indication that the zinc is disappearing and copper is taking its place.—Preparations are under way for extensive operation of the Butte-Balaklava properties in this district. Plans and specifications have been prepared by R. B. Dear for a new hoist, with capacity for 3500 ft., to be operated with compressed air. It will be the only plant so operated in any of the copper producing districts of the country. The Butte-Balaklava Co. has developed important orebodies on the 300, 500, 700, and 1000-ft. levels, and has its shaft down to a depth of 1280 ft.—The Anaconda mine at Butte, has been closed down for an indefinite period on account of increased volume of gases from the fire raging in the lower workings. Some ore is being taken from below the 1400-ft. level through the St. Lawrence shaft.—While no instructions for a curtailment of copper production have been received in Butte, mining men anticipate such orders. They say that the Amalgamated mines cannot be operated on a reduced output, that they must run at normal capacity or shut down.—The assays of the ore in the vein struck on the 900-ft. level of the East Butte mine showed 9.6% copper, 22 oz. silver, and a payable amount of gold. The vein is still 8 ft. wide.

NEVADA.

CHURCHILL COUNTY.

Contracts have been placed for the erection of the first unit of 10 stamps for the Nevada Wonder Mining & Milling Co. at Wonder. Preliminary tests made by F. L. Bosqui show that an extraction of 90% should be obtainable from the grades of ore averaging \$60 per ton. The mine has been opened to the 500-ft. level and several thousand feet of general development work has been done. The average value of the mine ore is \$30 per ton, of which 57% is gold and the rest silver.

ESMERALDA COUNTY.

The various mills and reduction plants now operating in Goldfield handled last week, according to figures compiled by the *Tribune*, a total of 6595 tons of ore valued at \$259,600, being an increase of 540 tons, valued at \$25,250, over the amounts of the previous week. The Consolidated mill handled 4200 tons, averaging \$40 per ton, or \$168,000; Florence mill, 845 tons, at \$35, or \$29,600; Nevada-Goldfield Reduction Works (including 600 tons of Combination Fraction ore), 800 tons, at \$40, or \$32,000; and the Combination mill, 750 tons, at \$40, or \$30,000. It is estimated that the daily average production of the Florence mill since the stamps first began dropping is 75 tons. This is rapidly being increased.—At the directors' meeting of the Goldfield Consolidated Mines Co., held in Washington, D. C., the first quarterly dividend of 30c. per share was declared payable on April 30, instead of March 31, as had been anticipated. It was stated that the reason for this delay was the fact that the Finance Committee had decided that the company shall at all times have a reserve of \$1,500,000 on hand before paying any dividend. The principal shareholders, and their holdings, are said to be George Wingfield, 500,000 shares; George S. Nixon, 250,000; H. C. Frick and C. D. Barney & Co., 500,000; Hayden, Stone & Co. and their clients, 700,000; the Hubbard interests of Chicago, 800,000; B. M. Baruch and associates, 100,000, and the general public about 700,000 shares.—A group of six claims has recently been secured by the St. Ives Leasing Co., in the Washington mining district on the East Walker river. This property was bonded to some San Francisco capitalists two years ago for \$50,000 and a payment of \$10,000 was made. The parties were unable to make further payments as they came due. During the past two years no work was done, and the claims became open to location. These are the claims that the St. Ives Co. has taken up by re-location.—An increased tonnage and of much higher value is being handled at the Florence mill; 135 tons of ore daily going through the 30 stamps now running. H. G. Morris, superintendent of the mill, expects to have the entire battery of 40 stamps at work in a few days, and another tube-mill is being set to aid the fine grinding. The Vantage Extraction Co. has experimented on

the Florence ore, and has obtained extractions of 97% with less than an 8-hr. treatment. G. E. Wyman, of the Extraction company, is in Goldfield seeing about the installation of some of his agitators.

HUMBOLDT COUNTY.

(Special Correspondence).—The Mazuma Hills Leasing Co. has opened up a 3-ft. vein of good-grade ore on the 265-ft. level. The find was made in the north drift. Raises are being run from both levels.—F. T. Caley, one of the stockholders of the Portland M. Co., at Cripple Creek, has purchased a large interest in the Mazuma Hills mine. The Mazuma mill is running steadily on ore from the Mazuma Hills and Reagan properties.—The Kindergarten mill is treating ore from several leases. A broken cam-shaft caused a practical suspension of activities for several days.—The main building of the mill of the Darby-Nevada Ore Reduction Co. is nearly completed and the installation of machinery will soon commence. It is reported that the company is contemplating the installation of 10 more stamps.—The Chafey M. & M. Co. is installing its custom mill and expects to be ready to receive ore within a few weeks. A large quantity of good ore is available.—Placer mining is attracting considerable attention at Chafey, and arrangements are being made to carry on extensive work. Machinery is being placed in position at several points. A fairly good supply of water is available.—The Cleghorn lease of the Consolidated L. Co., on Signal Peak ground, has installed a 3-drill compressor. The adit is in 450 ft. and will be extended 650 ft., to reach a depth of 600 ft. The adit is on the course of the vein and considerable ore has been developed.—A good deal of prospecting is being done throughout the district.

Seven Troughs, February 26.

LINCOLN COUNTY.

J. H. Maguire and H. G. Phillips have been successful in finding some fine specimens of turquoise on their property at Crescent, about 12 miles west of Searchlight. The neighboring holding is the Toltec, owned by J. R. Wood & Sons, Jewelers of New York.—W. W. Hurt, of the New York-Searchlight, is putting the finishing touches to his plant. The hoist is running and the electric plant is nearly ready for generating power. The compressor has capacity for running six drills, but while only three are running the extra power will be made use of for pumping purposes.

NYE COUNTY.

John G. Kirchen, general manager for the Tonopah Extension and Montgomery Shoshone companies, says that a mill for the Extension is now assured. All the necessary plans have been submitted to the directors and the orders are to be placed for the machinery. The mill will have not less than 30 stamps and will be constructed with a view of easily adding to the capacity without interfering with operations.—Denver lessees on the Tramp Consolidated, in the Bullfrog district, continue to take out good ore. Three sets have accumulated enough sacked material to make good shipments. They cut out the rich streaks and continue to ignore the big quantities of milling grade.—It is said that a vein over 40 ft. wide has been opened on the 155-ft. level of the Pioneer mine, with the opposite wall still unreached. Frank Keith, formerly of the Tonopah mine, is manager.—The Round Mountain Mining Co. is arranging to increase the capacity of the mill to over 100 tons per day. A compressor for 10 drills will also be shortly installed. Recent developments have resulted in the opening up of large reserves of milling ore.—It is reported that the Round Mountain Homestake Co. will shortly resume operations. The trial run and clean up of the Solid Gold M. & L. Co. has been made. Approximately 500 tons of ore worth from \$15 to \$20 per ton were handled. The test was satisfactory in every way. The capacity of the mill is 60 tons per day. Everything is in readiness to place the Mayflower mill in commission and it is expected to commence active work within a few days. A large reserve of milling ore is blocked out in the mine and several men are employed. Sydney Addison is superintendent. The Tono-

pah-Belmont Development Co. announces that the shaft on the Belmont claim, now 530 ft. deep, will be enlarged to 3-compartment and sunk to the 1500-ft. level. S. H. Brady is general manager.—The Round Mountain Alleghany Mining Co. has purchased the Orphan Girl, an adjoining claim.—The total output of the Tonopah mines for the past week was 5699 tons, of an estimated value (the shipping ore being valued at \$60 a ton and the milling ore at \$25 a ton) of \$142,475. The Tonopah company sent 3150 tons, the Belmont 960, the Montana-Tonopah 739, the Midway 100, MacNamara 250, West End 200, and Jim Butler 300 tons to the mills.

STOREY COUNTY.

The weekly report from the Comstock mines show that the Ophir shipped 230 tons to the Kinkead mill and 223 tons of second-class ore to the Butters plant. Most of the ore taken from the 2000-ft. level has assayed about \$23 per ton. Pending repairs to the electric pump in the Ward shaft, the 5-step centrifugal pump on the 2400-ft. level is keeping the bottom of the shaft free from water. In the Sutro tunnel, 15 ft. of advance were made driving through the cave, and an electric locomotive is being used to haul out the waste.

WHITE PINE COUNTY.

There were 33,751 tons of ore milled in January at the Steptoe concentrator from the mines of the Cumberland Ely Mining Co., the ore showing 3.09% copper, while the extraction showed a recovery of 76%. The total copper produced from the concentrator netted 1,600,000 lb., the company shipping out 1,100,000 lb. of blister copper.

S. S. Sorenson has been appointed superintendent of the smelter department of the Steptoe, in place of Walter G. Perkins, who has gone to Tanganyika in Central Africa. Sorenson has previously been in charge of the engineering work with the same company.

SOUTH DAKOTA.

LAWRENCE COUNTY.

It is reported that the Homestake Co. is planning to increase the present capacity of its slime plant. At the present time the plant is running 26 presses three shifts of eight hours each, and treating about 1800 tons of slime per day. It is said the company will build a spacious addition to the south end of the present building and install between 10 and 15 new presses. In these presses a new system of sluicing will be installed, whereby the present movable sluicing-machine will be done away with, and a much simpler device run by a shaft put in its place. The change will enable any or all of the presses to be sluiced at the same time, instead of only five as a maximum at present.

TEXAS.

ANGELINA COUNTY.

The officers and various stockholders of the Lone Star Mining Co. have been in Monterey looking over their mineral ground, which, after an idle period of a year, are now to be opened again. The company will run several adits at once, and prospects already proved will be worked.

UTAH.

JUAB COUNTY.

The new orebody found on the property of the Iron Blossom Co. is 15 ft. wide, and is considered to be an extension of the Colorado ore-shoot.—The East Tintic Co. has found a second face of ore 40 ft. below the first discovery. The new ore in the Uncle Sam holds strong, gold being found besides the silver-lead.

SALT LAKE COUNTY.

The Oregon Short Line has made the announcement that on April 3 a new rate will go into effect on ores shipped from the Goldfield and Tonopah mining camps to Salt Lake smelters, the rate touching ores of a certain grade only. Ores valued at \$20 to \$60 will be carried for \$1 per ton less than the present rate, while ores ranging from \$70 to \$100

per ton will be transported for 50c. per ton less than the present schedule.

WASHINGTON.

FERRY COUNTY.

The Insurgent mine near Republic, owned by Graham B. Dennis, of Spokane, and operated under lease by William Crummer and Samuel Kerr, is shipping ore to the smelter. The first four cars averaged \$39 per ton. The property is operated through a tunnel on the Lone Pine group, owned by the Lone Pine-Surprise Mining Co. Arrangements are being made to re-open several of the old properties this spring. Mining in the Republic district is a deep proposition, but before this was realized, many of the properties, prominent in the early days, had to be closed down and abandoned.

STEVENS COUNTY.

On the Dewey claim of the McKinley group (usually called by the company No. 6, there being 9 claims in the group), the cross-cut has passed 30 ft. from the foot-wall, and the hanging wall is not yet in sight. Analyses of the ore have shown the presence of copper, iron, and arsenic, in addition to the gold and silver contents. The company intends building a wagon-road from its property to the bridge across the Kettle river, at Rockcut.

OKANOGAN COUNTY.

The Conconully Copper Co., on the Salmon River Boy claim, has an open-cut 20 ft. long, showing ore from 2 to 3 ft. wide, containing silver, copper, and lead.

Mining in the Chesaw district is more active than it has been at any time in the last 10 years. The Grant Consolidated Mining Co. has several machine drills in operation, and much high-grade ore is being taken out. The shaft on the Apex property in the same district is now 250 ft. deep and found ore at a depth of 228 ft. One hundred and fifty tons of ore are on the dump assaying from \$30 to \$75 per ton.—The Molson Gold Mining Co. is remodeling its mill, installing rolls in place of stamps.

WYOMING.

CARBON COUNTY.

The reorganization of the properties of the Penn Wyoming Copper Co., announced from Cheyenne, shows that the United Smelters Railway & Copper Co., which is to re-instate the organization, is composed largely of the directors who had control before. E. M. Cobb, of Chicago, is president of the purchasing company; J. E. Haskell, of Bradford, Pa., vice-president; E. A. Norton, Denver, secretary, and among the directors are A. F. Baldwin, A. L. Hawse, and F. B. Draper.

CANADA.

BRITISH COLUMBIA.

There are about 550 men on the pay-roll of the Granby Consolidated M. S. & P. Co. at its Phoenix mines, and 350 men working at the smelter. It is the intention of the company to go ahead with the enlarging of the battery of furnaces, which will increase the capacity of the Grand Forks smelter another 1000 tons, giving them a daily capacity of 4500 tons; this work will be done in July or August.—The Le Roi No. 2, of Rossland, has declared a dividend of 2s. per share, payable March 11. It is understood that this is of the character of a quarterly dividend and will be followed by others at regular intervals.

ONTARIO.

The production of the Crown Reserve Co., at Cobalt, for the last two months has aggregated \$320,000, and places this mine among the foremost of the camp. The directors have decided to place the company on a regular dividend basis of 24% per annum, with extra distributions which will require payments of \$850,000 for the year.—The Kerr Lake Co.'s shipments for last month show earnings of \$67,000, and the dividend distributions require only \$40,000 per month. The company is shipping about two tons per day, netting 4500 oz. silver. For every ton sent out the company is trying to put three tons in sight.

Special Correspondence.

LONDON.

A Two Million Pound Development Enterprise.—Dolcoath Output.—Carn Brea & Tincroft.

Consolidations of mining operations are the order of the day in the Transvaal. A further step in this direction is the new scheme for raising capital by the Randfontein Estates Gold Mining Co., which owns large mines in the western part of the Rand. About a year ago a scheme was put forward by Sir J. B. Robinson, the controller of this group, for the amalgamation of the company with several subsidiaries, and for the issue of a million pounds of debentures. Owing to the depression in the financial market the issue was a failure. Since then Sir J. B. Robinson has been keeping the pot boiling himself in the hope of better times. The recent proofs of reduced costs on the Rand has renewed confidence in its future, especially as regards the extensive low-grade areas, and the time now seems ripe for proceeding with the development of the Randfontein group. It is stated that an issue of £2,000,000 worth of debentures has been underwritten, so that success is assured. The debentures are stated to be 6% and exchangeable later on for ordinary shares at some agreed figure. If this issue prove a success the development of low-grade Rand ores will advance rapidly. The whole of the two million pounds is to be used in working capital in developing orebodies and providing plant, a fact which in itself indicates the prodigious character of the scheme.

Dolcoath, the premier metalliferous mine in England, showed results for the second half of 1908 differing but little from those it has achieved during the last eight years. The average ore crushed has been 100,000 tons per year, and the concentrate sold 1800 tons. To be precise, the figures for the second half of 1908 were 49,869 tons of ore crushed, yielding 902 tons of concentrate, or a product of 40½ lb. per ton. The total amount realized was £70,238. Two years ago, in boom times, the receipts were £30,000 greater from the same amount of ore. The working costs were £61,494, and lord's royalties £4724, leaving a net divisible profit of £5891, which, with the amount brought forward, makes a balance of £9528. Out of this £8500 is being distributed as dividend, which is at the rate of 5% per annum. It is interesting to note that since Dolcoath was turned into a limited company in 1895, the total ore raised has been 1,210,674 tons, and the concentrate produced 25,846 tons. The gross receipts have been £1,844,254, the working costs £1,308,459, the lord's royalties £94,902, and the net profits £440,872. Progress in sinking the new main, or Williams, shaft is slow. The total depth is now 2274 ft., and the rate of sinking is only 42 ft. per month. The shaft is circular, and it is being lined with 9-in. bricks. It is expected to cut the main lode at 2800 ft., and it will greatly facilitate the working of the lower levels of the mine.

The next largest producer of tin in Cornwall, the Carn Brea & Tincroft, Ltd., has not been able to meet expenses during the year 1908. The results for the second half of the year show a production of 518 tons of concentrate from 34,790 tons of ore, that being a decided increase over anything yet done during the life of the present company. The produce per ton was 33 lb., as compared with 40½ at Dolcoath, and the average price obtained was rather less, owing to the ores not being so clean as those at Dolcoath. The receipts were £38,397, and working expenses £39,027. The lord's dues were £1388, and the net loss was £2018. This was a smaller loss than during the first half of 1908, when there was an adverse balance of over £6000. This company produces also wolfram, arsenic, and copper—a complex ore. For some years the directors have been aware that the mine and the dressing plant require a thorough overhauling such as is being effected at East Pool, but the time for raising new capital is not yet.

KALGOORLIE, WESTERN AUSTRALIA.

December Output—Small Rich Mines.—Deep Developments in Golden Mile.—Metallurgical Methods.—Slime Agitation.

December returns from the principal mines at Kalgoorlie were as under:

Name.	Tonnage.	Value of output.	Profit.	Dividend.
Associated	10,886	\$111,000	\$21,000	
Associated Northern Blocks	3,730	38,000	14,000	
Golden Horseshoe	23,634	275,000	100,000	\$375,000
Golden Link	3,600	31,000	—300*	
Golden Ridge	2,103	26,000	13,000	35,000
Gt. Boulder Proprietary...	16,306	249,000	129,000	325,000
Gt. Boulder Perseverance..	17,363	150,000	47,000	
Great Fingall	9,740	60,000	5,000	
Hainault	5,858	32,500	4,000

Sons of Gwalia South.....	1,900	22,500	4,800	

Western Australia.

*Loss. The Lake View Consols owns four-sevenths of this mine at present, and the ore is carted a distance of two miles and treated at the mill belonging to the power company. During the month several rich mill runs were reported from small mines in different parts of the State. A mine at Waverley yielded 1350 oz. gold from 18 tons of ore, and others were Boorava, 100 oz. from 8 tons, the Black Jack at Yalaginda, 580 from 8, Union Jack at Yuckanana, 281 from 62, and Nemesis, at Yuckanana, 211 from 30. The ore from

the first-named was a green talcose schist, with very fine regular lines of gold running through it, making the specimens exhibited uncommonly pretty to look at. There have been some good developments at depth in the Kalgurli, South Kalgurli, and Perseverance. The ore at 1900 ft. in the Lake View Consols appears to be low-grade; the shares are dropping back nearer their proper value. As a London journal remarked, it was absurd for the market valuation of the mine to raise \$1,000,000 on the strength of cutting \$250 worth of ore.

The broken crank-shaft at the Great Boulder main hoist has been replaced by a new one, and everything is in full swing again. The Associated has just completed erecting a large surface condenser to take the exhaust steam from all its engines. This condenser was made by Thompson, of Castlemaine, Victoria. There is a centrifugal pump driven by an Allen high-speed engine for circulating the water, and also a large 3-cylinder air-pump. The hot water is pumped to a large cooling tower of the usual type. The Horseshoe is putting in another A. E. G. turbo-generator of 500 kw. capacity. For many years past the Hainault Co. has been selling its concentrate to a local treatment company; but now that it has erected an Edwards tilting furnace, all the work will be done on the mine. The general mode of treatment of concentrate on this field is to roast in an Edwards or Merton furnace, mix with KCN, classify roughly in pointed boxes, grind the coarse portion to slime, and amalgamate the coarse gold in pans. All the slime is agitated, and finally treated in a filter-press with good results. On a few of the remote mines the raw concentrate is dumped into vats, and given a long treatment—even as long as three weeks—with KCN; but the residue is generally high enough in gold content for further treatment after weathering. The Hainault system of treatment is as follows: crushing in Blake crusher, feeding the ore from the bin upon two wide picking-belts (this is the only mine on the 'Golden Mile' that goes in for sorting, the waste being about 9%), which in turn feed two small jaw-crushers; the product is elevated by belt to the battery bins; 40 head of stamps fed by Challenge feeders crush the ore through coarse screens, the pulp going to 6 pans of the Middleton-Cable type. This pan is different to the ordinary kind, in that the muller cannot be raised or lowered when in motion, but the dies are forced up against the shoes by a suitable gear and compensating weights outside the pan; thus uniform pressure is maintained in grinding, irrespective of the thickness of the shoes. The pans grind coarsely, as any mesh desired may be fitted on to the side of the pan. The pulp from them runs over Wilfley tables, and from these it is pumped to settling or collecting vats, the sand settling, and the slime going to agitators to be finally treated in two filter-presses of 5-ton capacity each. The sand is elevated by belt to a number of small vats for usual treatment. A good deal has been written of late on agitation in high-tanks, under the names of the Brown, Pachuca, and others. In this field there are three systems of agitation, namely, the ordinary vat with gear-driven spindle and arms attached; the A. Z. agitator; and the type used at the Kalgurli mine. The first named has its faults, but is generally in use. In vats about 22 by 6 ft., the horse-power required is from 2 to 3, and agitation must continue from 12 to 20 hours. The cost per ton, including power, KCN, wages, and repairs, will reach 35c. As far as results by the A. Z. agitator go, the horse-power required is 11, time 1 to 4 hr., and costs about 30c. per ton. It is the Kalgurli system that I wish to emphasize, as a patent was granted to Brown, of New Zealand, for a combination of a tank from 35 to 55 ft. high by 10 to 13 ft. diam., with an air-lift in the centre. This agitator appears to be working with success, although an informant at Waihi states that the air-lift has been dispensed with at their Victoria mill, the results being equally good without it. For about 9 years the agitation of slime at the Kalgurli mine has been done in tanks 12 ft. 6 in. by 6 ft. diam., with vertical sides for 7 ft. 6 in., then tapering for 5 ft., the bottom being flat and 18 in. diam. By means of two 1-in. air-pipes running to the bottom of the

tank, the charge of slime is agitated. Formerly these tanks were covered, but in the enlarged mill the 20 tanks are uncovered, so that agitation may be observed. There is no air-lift in the centre. With 30 lb. air-pressure, agitation of roasted sulpho-telluride ore is continued for 4 hr. with over 90% extraction. The tanks are sunk in the ground to within 2 ft. of the top, and the man in charge has the whole lot under his observation. Each tank holds about one 5-ton press of dry slime, and is connected with the press-filling pumps by a 4-in. pipe. The costs of agitation by this method are 20c. per ton, air 6c., KCN 10, wages and maintenance 4. Water consumption during the past month at the Kalgoorlie mines was 30,841,000 gal., for about 140,000 tons of ore treated. The last 10 days of 1908 averaged 108° F. in the shade.

NEW YORK.

Metal Stocks.—Market Manipulated from London.—Shannon Copper Railroad.—Electric Steel Furnaces.

The course of the stock market, which for the past four months was fairly steady, the variations being within about 3 points, was suddenly changed on February 23, when a severe decline was experienced. A raid was made on the metal stocks, which declined from 10 to 15 points. It was evident that the raid was exceptionally well planned and executed. The storm centre circled around United States Steel stocks, which were driven from 52½ to 41½. The raid was started from London, where J. P. Morgan, William Rockefeller, and James Stillman appeared to be active. As soon as the New York Exchange opened, enormous selling orders were executed from London, which brought prices crashing downward like a house of cards. Most margins were wiped out within the first three hours. On the following day prices recovered from 2 to 3 points. On February 25 the copper stocks were subjected to a second raid, which carried the general market a few points lower. Large buying orders were then sent in by the pool managers, and it is probable that a Taft inaugural demonstration will be made, which will run prices up again close to those ruling before the raiding. The raiders were so successful that there is little doubt the operation will be repeated at no distant date. Those most interested in the raids are also largely interested in the copper trust, and there is a possibility that the trust will be operated in a similar manner to the United States Steel and Amalgamated Copper corporations. Experience has shown that larger and quicker returns are obtainable by operations on the Stock Exchange than at the smelters. That fact was learned in the early days of the Standard Oil Company. The directors of that concern keep a large part of their surplus income active in Wall Street.

The directors of the Shannon Copper Co., Arizona, have decided to carry out extensive improvements. In order to save the freight paid to the Arizona Copper Co., a railroad will be built at a cost of \$500,000 to connect the mines with the mill and smelter. A separate company will be formed and underwritten by four of the directors, and then debentures will be issued to the public. When this plan is carried out, the Shannon Copper Co., like the Amalgamated with its U. S. Metals Selling Co., will carry a little old man off the sea on its back.

The Tennessee Copper Company produced 14,464,585 lb. copper in 1908. This was the largest output in the company's history. The profits for the year, as shown by the annual report, amounted to \$354,768. A sum of \$50,000 was set aside for depreciation on plant. The cost of producing and marketing electrolytic copper amounts to 10c. per pound.

During the past seven years the electric furnace has been extensively employed in European steel works, particularly in Italy and Germany. Excepting the experiments in reducing iron ore made in a Heroult furnace in California, little has been done in electric smelting in the United States. It is probable, however, that conditions will soon change, as it is reported that the United States Steel Corporation has

purchased the Heroult patents and will equip several of its works with electric smelters.

The 12 smelters which the American Smelting & Refining Co. operates and owns in fee simple have a capacity of 4,365,300 tons of ore, whereas the actual amount smelted has averaged 3,500,000 tons annually. The company makes this matter public to the New York Stock Exchange in its application, which has been granted, to place in the listed department \$50,000,000 each of common and preferred stock, which heretofore have been in the unlisted department.

The company owns two refineries, that at Chicago having a capacity of 84,000 tons of refined lead and 16,400,000 oz. refined silver and gold, and the Perth Amboy plant, having the capacity to handle each year 66,000 tons of refined lead and refined copper each and 36,000,000 oz. refined silver and gold.

Map of Arizona Showing Position of Cananea.

In detail the smelters are:

	Capacity, Tons.	Furnaces, Number.
Globe, Colorado	322,000	7
Pueblo, Colorado	328,000	7
Ellers, Colorado	295,000	6
Durango, Colorado	146,000	4
Arkansas Valley, Colorado	509,000	10
Murray, Utah	523,000	8
East Helena, Montana	235,000	4
Monterrey, Mexico	460,000	10
Aguascalientes, Mexico	720,000	10
Chihuahua, Mexico	153,000	3
National, Illinois	60,000	2
Perth Amboy, New Jersey	140,000	3

The Company also owns the Grant plant, which is within the city limits of Denver and stands on 120 acres of land, but this is not being operated and has been practically dismantled.

Aside from these plants, which are directly owned and operated by the American Smelting & Refining Co., there are a number of other plants operated by subsidiary concerns. For instance, the Consolidated Kansas City Smelting & Refining Co., every share of which stock is owned by the American Smelting Co., owns and operates a smelting plant at El Paso, Texas. This covers 1500 acres and has a capacity for treating 492,000 tons annually in its 10 furnaces.

At Omaha the Company operates a smelter and refinery upon a leasehold running for 18 years from this time. The

smelter has two furnaces with 82,000 tons annual smelting capacity while the refinery can treat 156,000 tons of refined lead a year and 36,000,000 oz. refined silver and gold. The copper converting plant has a yearly capacity of 12,000 tons of blister copper. The Company approximates the value of its smelter's product at \$70,000,000 a year. The annual refineries product is as follows:

Gold	1,250,000 oz.
Silver	66,000,000 oz.
Copper	66,000 tons.
Lead	225,000 tons.

The total value of refined metals sold annually by the Company approximates \$97,000,000. The Company owns and operates in Mexico ten mines, five of which at Sierra Mojada, Chihuahua, have an annual output of 33,000 tons; four at Santa Eulalia in the same State, with an annual output of 60,000 tons, and one at Asientos, State of Aguascalientes, with an annual output of 72,000 tons.

According to estimates just made, the decline in the market value of 35 listed copper stocks aggregates \$135,000,000 as compared to the highest prices in 1908. There has been a drop of over \$30,000,000 in Amalgamated alone, \$8,500,000 in Butte Coalition, \$8,000,000 in Calumet & Hecla, and \$9,400,000 in North Butte shares.

CANANEA, MEXICO.

Copper Production.—Metallurgical Operations.—Centralizing Power.

The copper production of the Cananea Consolidated Copper Co. for the month of January was 3,800,000 lb., and the production in February was practically the same, as the daily output has been averaging 67½ tons. The mines, including the lime and iron quarries, are delivering to the concentrating and spreading beds about 3400 tons of flux and ore daily. Of this amount over 500 tons of lime and iron are used in the mixture, the remainder being first and second-class ore.

The Oversight mine is by far the largest producer, with a daily output of 930 tons. The output of the other mines of the company is about as follows: Veta No. 5, 580 tons; Elisa, 365; Duluth, 285; America, 270; Capote, 180; Puer-tocito, 170; Kirk, 50 tons. Early in January work was resumed in the Kirk mine, which has been closed since before the general shut-down over a year ago. The known orebodies in this mine are small, but the ore is of good grade and metallurgical character, averaging higher than 7% copper and 30 to 35% each in iron and sulphur, and is low in silica. Comparatively little development has been done. There is a large slightly mineralized area, and the representatives of the U. S. Geological Survey who made a careful study of the company's holdings 18 months ago think the Kirk mine one of the most promising in the district. Operations for ore-production have also been resumed at the Capote. Of the new development in the mines, the most important is the driving of two long tunnels, one in conjunction with the Phelps Dodge Co., developing the ground of both companies. This tunnel is being run from above Chivaterra toward the Elisa mine, and the other from the head of the Democrata gulch in a southeasterly direction under a heavily iron-stained country, the hills rising abruptly from the mouth of the tunnel. This latter tunnel has already cut for some distance ore carrying 2% copper. At the reduction works are six blast-furnaces, a reverberatory furnace, and two converters in operation. The average daily charge of the blast-furnaces, exclusive of coke, for the month of February has been about 2250 tons. The reverberatory is handling 190 tons of the flue-dust daily. The McDougal roasters are at present shut-down, there being sufficient flue-dust from the six furnaces to supply the reverberatory. Construction work on the furnaces is complete, eight being in readiness. A matte-pit is being constructed at one side of the spreading beds. This pit is to be used for the reverberatory matte, which will be re-claimed by a steam-shovel and sent to the blast-furnaces instead of directly to the converters, as is done at present.

The object of this change is to increase the matte-fall in the furnaces.

For several months Mr. Langton, formerly mechanical engineer for the Phelps Dodge interests, has been in Cananea working on the problem of centralized power-production. The plans are as yet incomplete, but a compressor with a capacity of 6000 ft. of free air has been ordered. This compressor will be installed at the main power-house and air will be piped to a number of the mines. It is planned to use air for the Duluth, America, and Capote hoists. Air for the drills in the various mines will also be compressed at the central power-plant. The air will be re-heated at the terminals.

There are electric hoists operating at the Elisa and Kirk shafts, and recently an electric pump has been installed at the Duluth mine, the electric power being produced at the main power-house. Gradually the power-production for the entire property will be centralized. The use of fuel oil has been extended to the Veta No. 9 and Capote boilers, effecting a saving of from \$150 to \$200 per day. The waste heat from the reverberatory furnace produces about 600 hp., which, together with the larger tonnage smelted since the change to oil, adds another item to the many improvements constantly being made.

SALT LAKE, UTAH.

Ray Consolidated Development.—Option on Tintic Mines and Smelter.—Smelter in Pine Canyon.—New Railroad to Ely.—Fink Process.—Boston Consolidated.

D. C. Jackling, general manager of the Ray Consolidated copper properties in Arizona, has just returned from a two weeks' visit to the mines. He says the officials in charge have 350 men employed opening up the properties, and plans are being laid for a mill and smelter. They also have an engineering force selecting a route for the railroad to connect the mines with the plants. The drills are proving the continuation of the orebodies, and Superintendent Wiseman reports that they have the assurance of a 2% body of copper ore sufficient to keep a mill of 3000-ton capacity busy for years. The men controlling the Utah Copper Co., together with English capitalists, dominate the new enterprise. Mr. Jackling says they will show as large profits in the operation of these mines as are now being made by the Utah Copper.

Options recently obtained on the Colorado mine and the Tintic smelter, at Tintic, call for the payment of \$4,000,000 for the mine and \$1,200,000 for the smelter. The mine has already paid \$1,225,000 in dividends, and is regarded as one of the richest silver-lead properties in Utah. The smelter has only recently been built and placed in commission. Three lead furnaces, with a daily capacity of 225 tons each, are in blast, while a copper furnace and a fourth lead furnace are ready to blow in at any time. Both the mine and smelter are controlled by the Jesse Knight syndicate, which has had a most successful career. The option was obtained in the interest of the Cole-Ryan syndicate, and an examination of the mine is to be conducted by their engineers within a few days. It is understood that they are desirous of obtaining a good silver-lead property in this State, but they do not seem disposed to take over the smelting plant. They have almost completed arrangements for building works for the International Refining & Smelting Co. in Pine canyon. Surveys have just been completed for an ore-hauling railroad to connect that point with Deep Creek and Ely. The surveys show the length of the proposed line to be approximately 250 miles, and it is understood that this would eliminate the possibilities of the International Smelting & Refining Co. building a smelter near Ely for the treatment of the Giroux Consolidated and custom ores. This line would haul the ores from Ely and Deep Creek to the Pine canyon plant, and it is intimated that the Cole-Ryan people will take an active part in having this road constructed in the shortest possible time. The Pine canyon smelter will be ready to receive ores within a year, accord-

ing to a statement by the smelter officials at this point. The spur line from the Salt Lake route to the smelter and Tooele City, which will be 6½ miles long, will be completed by May. As much of the structural steel and some of the equipment will soon be started from the East, E. P. Mathewson, manager of the smelter, says they will have everything in readiness to complete construction earlier than was at first planned.

During February, 5,023,181 shares of mining stock were dealt in on the Salt Lake Exchange. In a single week of the past month more shares were transferred than for the entire month of February of last year. Edward Fink, the inventor of the smelter which has produced blister copper direct by one process from the Boston Consolidated concentrate, announces that all necessary alterations have been made for the run with oil as a fuel, and that the plant will be placed regularly in commission within a few days.

Sidney J. Jennings, who was elected director and member of the executive committee at the last annual meeting of the Boston Consolidated shareholders, is out from the East. Mr. Jennings is consulting engineer to the company, and will spend some time inspecting the properties at Bingham, and the milling plant at Garfield. Steam-shovels will again be placed in commission at the Boston Con. mines. After the overburden has been removed, the company will be in position to keep its mill supplied to the full capacity of 3000 tons daily from its porphyry ores. About 1500 tons are being mined daily from the sulphide deposits of the company, and it may be autumn before the entire property can be placed in position to produce heavily from both the sulphide and porphyry deposits.

MEXICO.

Greene Concession Forfeited.—Cole-Ryan Interests in Western Chihuahua.—Loaning Money for Mine Development.

On February 9 the immense section in western Chihuahua on which W. C. Greene had a concession of a zone of exploration, was declared forfeited and thrown open to denouncement, or location. It was generally supposed that there would be a rush of denouncements, as during the life of the concession there has been continual talk of great finds being made within the zone. For some reason, however, the denouncements are still being held up—probably because, as is usual in such cases, the non-attainable is always the richest. Now that it is attainable it is not proving up so well. It was thought for a while that the throwing open of this zone, which was delayed for a month, would be restrained in some way by the Cole-Ryan people, who have acquired certain of the Greene interests in western Chihuahua. But apparently they made no effort to do so, and just what their program may be for that portion of the Greene properties they have taken over is not known, nor is it definitely known whether they have interested themselves in more than the lumber lands held by the Sierra Land & Lumber Co., which is also one of the Greene companies.

Considerable hope is being held out to the Mexican miner by the Consolidated Metals Co., of Mexico City, which is offering to advance money on mines that will stand examination. This should be a boon to those who lack means to put the properties on a productive basis. The Consolidated Metals Co. was primarily an ore-buying company, and is intimately associated with the Vogelsteins, the United States Smelting, and others, which comprises a group of miners, ore buyers, smelters, and metal sellers, appearing as complicated to the outsider as the A. S. & R. Co., the Guggenheim Exploration Co., M. Guggenheim's Sons, and the American Smelters Securities Co.; but the Consolidated Metals has within the past year become so involved in Mexico, particularly in Oaxaca, that it is now difficult to say whether the principal interests are ore buying, mining, or railroading. This latest move, however, of loaning money to the worthy miner, if properly carried out and with fair conditions to the borrower, should prove of benefit to all concerned.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

The grade of the Miocene ditch, 40 miles in length, is 3.37 ft. per mile for the portion that runs through frozen ground. The ditch is 14 ft. on the bottom with a slope of 1 to 1.

Huntington mill work on gold ores is best conducted without the addition of mercury inside. The losses of amalgam are greater than any compensating advantage, and 'float' amalgam is exceedingly difficult to arrest, as all mill-men know.

The only important gold-vein mine in northern Alaska is the Big Hurrah, near Solomon, on the Seward Peninsula. This mine was operated by Charles D. Lane, but it is now idle. The gold occurs in veins of quartz traversing graphitic schist. The graphite is said to have hindered amalgamation in the mill.

Gold mines as investments fall within a class of rapidly wasting assets. It is sometimes possible to make an approximate estimate of the period when the deposit will have been exhausted and the operations of the concern will have ceased. Mining investments, therefore, differ radically from those in railroads or industrial enterprises, which can usually be counted on, for the purposes of an investor, to last indefinitely.

Sodium sulphate, or Glauber salt, occurs widely disseminated throughout the desert regions of the Western States. It is precipitated in large quantities in winter from the waters of the Great Salt Lake, Utah, and is washed upon the shore, forming masses several feet in thickness. There is practically no market for sodium sulphate, the available deposits being so many and the uses few. The refined salt is worth about \$6 per ton at tide-water.

Gabbro is a granular igneous rock consisting chiefly of pyroxene and feldspars, the pyroxene being as abundant as the feldspars. Olivine is a common accessory. The color is usually dark gray or greenish, to black. It is a basic rock, containing about 50% SiO₂. Gabbros are frequently found in the form of schists, resulting from pressure. Iron is frequent in gabbros, magnetite and titaniferous ores prevailing. Sulphides of copper are also associated with these rocks in many parts of the world.

Gold veins of importance are rare in mica schist; on the other hand, the gold-bearing quartz stringers through schist have for the most part been responsible for the great placer deposits of the world. In many schistose regions, however, veins of workable size are occasionally found, such as those of the California gold-belt. The common characteristic of quartz-veins in schist is that, being of the 'cementation' type, they lack persistence and uniform mineralization. Spaces of discission which had subsequently been filled by cementation quartz, are asso-

ciated usually in zones, so that cross-cutting is needed to reveal new veins. The amount of dead-work is accordingly relatively large. As an off-set to the disadvantages the gold is usually readily amalgamable, and high recovery by relatively inexpensive methods is feasible.

The North Star mine at Grass Valley, California, has reached a depth of 5400 ft. on the dip (28°) of the vein or 2086 ft. vertical. According to Mr. Arthur DeW. Foote, the manager, the vein is larger and shows more gouge at the bottom than on the upper levels. The ore remains as rich. The walls of the vein are farther apart and the quartz is generally in layers or stringers with country rock between, so that of the 6 ft. sent to the mill fully 60% is waste, reducing the average yield to \$12 per ton. On the upper levels the mine averaged 18 inches of \$18 ore. The reserves of ore above the 4000-ft. level are ample for several years; no stoping is in progress below 4000 ft., although the ground is being tested by means of levels and raises. After the vein has been once drained, the water, below the 2000-ft. level, amounts to only 250 gal. per minute and does not vary with the seasons. Above 2000 ft. the rainfall is felt quickly and in spite of careful surface drainage the seepage underground is from 600 to 800 gal. per minute at the present (January) time. The mine workings now cover an area 1½ mile by ¾ mile, but no ore-shoots are defined, there being no evidence of discontinuity in the distribution of ore.

The weight of gold in a quartz specimen can be closely approximated, if there be no admixture of pyrite or other foreign material, by a specific gravity method. Let

- A = specific gravity of the gold.
- B = specific gravity of the quartz.
- C = specific gravity of the specimen.
- x = weight of the gold.
- y = weight of the quartz.
- W = weight of the specimen.

	x	y	W
Then	A	B	C
and	x A	y B	W C

If now the values for the specific gravities of gold (19.25) and quartz (2.65) be substituted, these equations reduce to

$$x = \frac{W}{18.9} \left(\frac{C - 2.65}{19.25 - 2.65} \right)$$

which gives in a simple expression the weight of pure gold in the specimen. It must be remembered that the specific gravity of both gold and quartz may be different from the values given, owing to silver alloy in the gold, and to variations in the density of the quartz, so they should be determined independently when it is intended to accurately estimate the quantity of gold. In a similar way the ratio between the weights of two minerals, such as galena and sphalerite, can be found, when they contain no other substance intermixed.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

American Institute.

The Editor:

Sir—I wish to thank you most cordially for your recent editorial on the nominations for officers of the A. I. M. E. I think you have done a real service to the Institute, and to the mining and metallurgical professions. Your objections to Mr. Ralston are pithily and fearlessly expressed, and do not, in the slightest degree, reflect any discredit on him; in fact, I think they imply that his nomination was due to his individual prominence. The point you raise, that he cannot be recognized as a representative of the mining and metallurgical professions, is timely and sound. Your characterization of the membership of the A. I. M. E. is strictly true. I wish you would follow up the matter and show that this is not necessarily a defect in its organization. I think it should be made the greatest element of its strength. There is a positive demand for a voluntary association of all those who are either directly or proximately connected with the mining and metallurgical industries. The founders of the Institute showed their faith in this idea by welcoming everyone who chose to join them, so long as he was a worthy member of society and was pursuing the objects for which the Institution was formed. There never has been any claim for equality, either in natural gifts or attainments, made among the members. It is recognized that a boy throwing by hand the valve of a pumping engine might develop into a man of the highest rank. But the heterogeneity of the membership of the Institute requires a unity of spirit. Your point is, that we should choose representative men, and in the case of a professional society, they should be professional men. With the growth of our nation every institution of national importance must develop a proportionate growth, or be atrophied. Believing as I do, that the exercise of Federal powers was wisely restricted within State boundaries by the constitution, I think the effective agents of national progress are voluntary associations of individuals actuated by a common spirit, working for a common object, not entirely selfish, but tending to the common welfare. The profession of medicine and surgery gives an illustration to the point. Their city, county, State, and national organizations are all united by a single idea: the development of the dignity and usefulness of the profession. The associations of lawyers have also the same objects, and their combined influence is noteworthy. These various associations, of medical men, scientists, lawyers, bankers, business men, and others, are co-extensive in their special fields, and should not interfere with each other's functions. They are like different systems of branching nerves, each affecting and directing their own congeries of vital processes in the body

politic. Between them there must be established a certain comity. Just as there is needed a predominant directive force in each functional organism, so there is needed some control, by which they can act without interfering with each other's action. Therefore, just in proportion as the membership of the Institute is made general, so should its actuating spirit be made evident; and the rules of behavior and practice, which have been found essential in the development of civilization, be carefully followed.

To cite a single case, I think the discussion by the Institute at the recent meeting, or even the reading of a paper, on a sea-level canal at Panama, ill advised. In the Institute there are many prominent civil engineers, entirely qualified to discuss this question; probably all of them are members of the American Society of Civil Engineers, to whose province this problem of construction belongs. It appears to me to show a lack of courtesy for mining engineers and metallurgists thus to invade the field of an equally national society. If the question concerned the effect on the mining industry of a sea-level, rather than a lock canal, it would be quite within our own domain. I go further and say, the time chosen for the discussion is inopportune. A canal is conceded to be a commercial and military necessity. The plan has been decided upon, the work is rapidly progressing. Doubtless it will be worth all it will cost. The first trans-continental railroad furnishes a parallel instance. It was a means of communication thought, by those who were responsible for the preservation of the union, to be of vital importance to the continuance of the national life. It was a heroic achievement, and was paid for by a nation. The money-cost of such public services, in emergencies, cannot be scrutinized like ordinary transactions of business. The time for such a discussion was years ago.

I hope you will continue to exert your influence to sustain and uplift the professional tone of the Institute, and bring the national engineering societies into closer relations.

F. L. CLERC.

Denver, February 17.

Protection of Investors.

The Editor:

Sir—I have read with much interest the discussion entitled 'Protection of Investors', in the columns of your most recent issues, and although I feel that I am not able to give information necessary to overcome the existing evils, practised by the mining engineers, mine managers, promoters, and investors in mines and mining stock, yet I do think that I have had in practice for two years a remedy, which, if adopted by all mining engineers, will largely overcome the troubles that exist, and will be of some protection to the new investor. I do not believe, however, that such practice will be adopted by the mining engineers or mine managers, owing to the fact that it would inflict an injury to a great many of those who have already invested, also upon the mining engineer who may adopt this practice, as it has done to the writer.

When I opened my office at Seattle in 1906 I carried a card in a certain mining journal, openly stating that I would furnish a sworn affidavit with my reports. Today I am only able to show a copy of one report, written for an individual owner who had a property for sale. This property was a bonanza, hence the reason for his desiring a sworn affidavit with the report.

For the last eighteen months my only examinations have been for individual stockholders who have had their legs well pulled from time to time, and desired to know whether or not it was best to drop their assessment and lose all, or go ahead and put in more money. And for each and every report I have written for stockholders, I have had sums offered me, by the promoter, far exceeding the fee charged the stockholder for my examination, to report favorably. This fee was usually payable in stock.

It is still a question in my mind as to whether this remedy will overcome the existing evils or not, but it seems to me that if adopted by all mining engineers it would greatly help. Of course, the mining engineer who furnishes a sworn affidavit with his report can only state that to the best of his belief same is true; and even though he could not be held for perjury, if same were not true, it should have a strong tendency to curb the engineer who is too apt to say there are millions in sight when writing a report on a developed or undeveloped property for the dishonest promoter, who, on his side, is always ready to offer a handsome fee in the way of stock for a flattering report.

JAMES H. FOX.

Vancouver, B. C., February 8.

California State Mining Bureau.

The Editor:

Sir—In your issue of February 6 appeared an article from the pen of J. M. Hyde, attacking the State Mining Bureau and its management, and following along the lines of previous attacks made by your journal on the Bureau and myself. So that your readers can more thoroughly understand the motives underlying these attacks, it should be said that the discharge, removal of, or resignations demanded by me of different employees, caused the untruthful and unwarranted abuse. Mr. Hyde can be classed with the discharged employee, and the employers of labor know what that means.

In his remarks, Mr. Hyde voices the same cry as the Editor: that the Bureau is controlled by Southern Pacific influences, and that I have aided the latter in fighting the Western Pacific. Now, I want to suggest to all the soreheads that if they are going to lie in the endeavor to gain their points, that they lie with reason. Neither the State Mining Bureau nor myself has ever raised a hand against the Western Pacific. My efforts were directed against H. H. Yard, and as Mr. Yard will agree, and as he stated numbers of times, he had no connection with the Western Pacific, for did he not form the dummy North California Mining Co. in 1902, for the purpose of locating with placer locations the 265,000 acres of timber land in Butte and Plumas counties, which I

characterized as a big steal, and which was reported by me to the Government on November 7, 1902. Further, did not Mr. Yard organize the Butte & Plumas Railway Co., with the following directors: H. H. Yard, E. H. Benjamin, A. M. Hunt, A. Ekman, and Carlton Gray, and did not Curtis Lindley appear as attorney for H. H. Yard and this railway when the articles of incorporation were filed on October 13, 1902?

Perhaps this little untold history may not generally be known, but the records of the Secretary of State will bear me out, as will also the press of the State of California; therefore, if the Western Pacific was masquerading behind Yard or the companies mentioned, their identity was unknown at the time of my attack. The blow that was given Yard by the United States Land Office decisions condemning his placer mineral locations as invalid, and that they were made to secure the timber upon them, would also appear to have inspired some of the animus exhibited to me.

Speaking of these influences, Mr. Hyde's inconsistency is ridiculous. In one breath, he says that the Southern Pacific directs all the affairs of the Bureau; in another, he admits that he was asked by me to take the appointment as Curator, and for once he has told the truth, as the latter statement is correct. He could, if he wished, also state that he knew of other appointments which were made without the necessity of a political pull, and which were made on trial, subject to the employee showing that he was capable of "holding down his job." Mr. Hyde was given a like opportunity, but he occupied too much time in theorizing, with the result that nothing was accomplished in the Museum.

He then concluded that he was cut out for the position of Field Assistant, and in order to give him an opportunity of proving his ability, he was appointed to this position, and sent into the field, with the necessary equipment, and directed to secure samples of oil for analyses from the different oil-fields of California. He carried a letter of instructions to sample all oils direct from the pump at the wells. Out of about seventy samples obtained, three were taken according to directions. The balance were obtained from sump-holes and tanks where the oil had been exposed to the sun from one to six months. Yet this savant, with his head swelled out of all proportion by the sense of his own importance, concluded that his ideas were so far superior to those of his chief, that it made no difference how or where the samples were obtained. After his recall to the city, and notwithstanding his direct disobedience of orders, he insisted on the State giving him a two weeks vacation at Lake Tahoe. I have seen several exhibitions of 'nerve', but this capped the climax, and Mr. Hyde was told that he would be given a vacation, and a long one at that.

It was then that he rushed into print with his troubles, but instead of convincing anyone that he was the only man on earth who was gifted with administrative ability, he showed himself to be the sneaking ingrate that he is—and one unworthy of the confidence of any employer. The Board of Trus-

tees investigated Mr. Hyde and his charges, which were found to be entirely without foundation. However, as I remember, the Board censured me (and I admit the justice of it) that in future selections of employees, I should exercise better judgment, and demand proper endorsements as to ability, and not appoint them (as was done in the case of Hyde) on their own estimate of their ability.

As to the employment of a relative, there was no reason why I should not employ him. He was engaged to do the work properly of collecting oil samples which Hyde was not capable of doing, and as to ability, said relative had been mining for twenty years before said Hyde had commenced the A.B.C.'s of a theoretical education.

The statements of Hyde in relation to the Copper bulletin are lies made out of whole cloth. The bulletin will testify for itself. Due credit was given to everyone connected with it, with exception, possibly, of the men who set the type, the proof-reader, and the boy who oiled the press. I unintentionally forgot to mention in my letter of transmittal that Mr. Hyde may have assisted the janitor in carrying some of the Copper bulletins upstairs when the printer delivered them, but I could hardly anticipate what he would do.

The statements made by Hyde in relation to the bulletin on Saline Deposits also characterizes him as a member of the Ananias Club. In this bulletin, as well as all others, no individual's mining property, or that of any corporation, is boomed, no favorites are played, and nitre deposits, owned by different persons, were treated alike. The same system is used in the bulletins as was used in reports issued by my predecessors.

Again the bulletin speaks for itself to unprejudiced readers. If Professor Bailey named a lake after me, because, as he asserts, it was through my instrumentality that the desert section of the State was brought into prominence, he is to blame for that, as he will admit. I do not know that I have felt particularly flattered at the honor conferred, as this lake was a 'dead one'. I might say right here that with all Mr. Hyde's and my other enemies' endeavors to 'knock' before I am through with them, they will find that I am very much alive.

Of course, the learned (?) theorists know how much better the Bureau could be conducted if one of them was in charge. Perhaps the disappointed ambitions of Mr. Hyde and a few others to become State Mineralogist might also be ascribed to some of this gnashing of teeth. My enemies advocate a better administration, yet, if an employee fails to do his duty and is dropped from the payroll, a wail goes up from the clique whom I have fought and will continue to fight. This talk of having the interest of the Bureau and the mining industry of the State at heart is hypocritical bosh. I see the tears by the skip-load running down the faces of those who are so sorry to see the Bureau go to the demnition bow-wows, and I know that their feelings can only be allayed by the possibility of getting me out—or wrecking that which they cannot control. But their purpose is too appar-

ent, and their work too raw, and if they think for a moment that I have "laid down the gloves," let all the sore-heads, discharged employees, timber thieves, mining fakers, the rag tag and the bob-tails come on. As usual, I will be found in my office attending to business.

Regretting, Mr. Editor, that I have taken so much of your space, and wasting printer's ink answering the slimy ooze which has called forth this letter, I remain,

L. E. AUBURY.

San Francisco, February 19.

[The foregoing epistle needs but little comment: it testifies eloquently to the character of the man who officially represents the mining industry of California. We would have been justified in consigning this scurrilous screed to the waste-paper basket, but the publication of Mr. Hyde's letter made it proper to give equal prominence to Mr. Aubury's rejoinder. Only one further remark is called for: the Butte & Plumas Railway Co. was organized in the Gould, that is, Western Pacific, interest with a view to obtaining a strategic position by means of a right of way through the Beckwith pass. Also, the mining locations taken up by the North California Mining Co. were a blind intended to make the local people think that the project was a local enterprise independent of any trans-continental railroad schemes.—EDITOR.]

Agreement of Assays.

The Editor:

Sir—How close should two assays check with one another, or, to put it differently, what variation should be allowed between the smelter assay and the control, without calling in an umpire? Obviously, where one would be justified in calling for an umpire, if there was a difference of 0.05 oz. Au, in an ore assaying 0.20 oz. per ton, he would not be justified in so doing if the ore ran, say, \$10 per ton. I think it would be well if some of our leading chemists and assayers would express themselves on this subject, and state how close they think two chemists should agree in reports on the metals and other substances reported in a smelter analysis, using the best technical methods. It would tend to give the profession a standard to work by, and would help to protect us from the layman, when we do not check exactly. I might state that at the 'Laboratorium Fresenius' in Wiesbaden, Germany, using methods of exact analysis, a difference of 0.3% on a basis of 100 is considered very good. This amounts to an error of three in one thousand.

E. R. RICE!

Wickenburg, Arizona, January 10.

Tin has been found in Northern Nigeria in Africa. Nigeria was constituted a British Protectorate in 1900. The tin deposits were discovered as a result of railway construction across the Bauchi highlands. These deposits have been favorably reported upon by W. G. Churchward of the firm of John Taylor & Sons of London.

RESCUE-WORK IN MINES.

At the United States mine-experiment station at Pittsburg, two discoveries have been made which will tend to decrease the number of deaths in mines. It has been demonstrated that a number of the so-called 'safety' explosives are unsafe; in fact, the statement is made that with the present explosives used in coal mining, the shot-firer takes his life in his hands every time he touches off a fuse. It is the purpose of the Government to continue these experiments until the explosives of the country are standardized in such a manner that the miner will have a definite knowledge of their qualities. A bulletin will soon be issued recommending as permissible explosives such as stand the test.

Important and far-reaching experiments have definitely shown that coal-dust is an explosive equally as dangerous as fire-damp. This has been a mooted question among mining engineers and miners, many

Members of Government Rescue Corps Equipped With Oxygen Helmets Ready to Enter Mine.

insisting that it is impossible to explode coal-dust unless there is gas present. That coal-dust will explode in a mine where there is no gas has been repeatedly shown to operators and miners at the testing station. The experts at the station are now endeavoring to discover some method by which this dust can be prevented from being a serious menace to the miners. Experiments in wetting it have been made, but nothing of a definite nature has as yet been learned, except that coal-dust does not ignite when there is a large amount of moisture in it.

The purpose is to approximate closely the conditions in a mine. Tests of dynamites and powders are made in a mammoth boiler-plate cylinder, previously filled with gas or coal-dust. The cylinder is 100 ft. long and 6 ft. diam. Safety valves have been placed along the top and are left unfastened in such a manner that when the explosion occurs the valves fly open on their hinges. A series of portholes on the side, covered with one-half inch glass, enables those conducting the experiments to witness the results from an observation house 60 ft. distant. Natural

gas is used at the station for fire-damp, because it corresponds closely to that deadly gas.

These investigations are expected to obviate employing improper explosives, as well as the improper use of suitable explosives. The use of too high charges or of unnecessarily violent explosives, shatters much good coal, and converts fuel into dust which may itself be explosive and become productive of further damage. Such explosions also loosen the roof of a coal mine, which may fall later and produce fatal accidents.

In addition, important experiments are being made in rescue work. One part of the station has been fitted up as a miniature coal mine. This is a large glass-encased, air-tight room which contains difficult passages such as are found in coal mines. There are also various obstructions similar to what would be found in a mine after it had been wrecked by an explosion: also dummies weighing 150 to 200 lb., representing asphyxiated miners. This room is filled with deadly gas and a rescue corps of men in process of training for the work enter, clad in helmets which supply them with oxygen while they work. The men remain in this chamber for two hours, removing obstructions, picking up the dummies, placing them on stretchers, and carrying them away. There is also in the room a machine which records the amount of work a man may be expected to do while wearing one of these helmets. One-half of the large building in which this rescue-room is situated is used as an auditorium, and several hundred miners and operators have watched the rescue-drill through the large glass windows which separate the auditorium from the gas-filled chamber. Although there has been little opportunity for the rescue-corps to demonstrate its efficiency at the mines, it has nevertheless done some good work. Once the helmeted men, while fighting a mine fire, succeeded in bringing an unconscious man to a place of safety, where he was given oxygen-treatment and restored in a short time.

It is not the intention of the United States Government to furnish rescue-corps whenever there is a disaster. The present corps was organized with the idea of encouraging the mine owners and the miners to form such organizations. Invitations have been issued to operators throughout the country to send picked men to the experiment station, where they may watch the Government rescuers at work and later go through the same training themselves, in order that they may gain the necessary confidence in the use of these helmets. A number of the large mining companies are organizing rescue-corps at their mines, fully equipped with oxygen helmets.

In 1907, more than 3125 men were killed in the coal mines of the country—a death rate of 4.86 for every 1000 men employed. This is from three to four times as many men per thousand as are killed in any coal-producing country of Europe, where experimental stations such as the one at Pittsburg have been in operation for several years.

Chromite bricks should not contain more than 15% clay. With larger proportions the alumina renders the mixture more fusible than kaolin.

TRAVEL IN COLOMBIA.

Written for the MINING AND SCIENTIFIC PRESS
By COURTENAY DE KALB.

Some of the golden opportunity in Colombia has been pointed out in the MINING AND SCIENTIFIC PRESS by articles from the pens of F. F. Sharpless and F. Lynwood Garrison, and also by editorial comment. Colombia has remained an almost unknown land, although eminently accessible, because of political disturbances and the fear in which foreigners hold a tropical climate. Both causes are serious deterrents of enterprise. The political difficulties have been happily terminated through the confidence reposed in President Reyes. In fact, before his accession to the presidency peace had been established under President Marroquín. The country has evidently passed beyond the revolutionary epoch.

So-called tropical diseases introduce questions concerning which the doctors are by no means agreed, but the experience of prudent travelers has demonstrated that the average European may live with security in the steamy tropics by observing certain precautions. The principal ills befalling a stranger in such a climate are malaria and hepatitis. One is likely to be complicated with the other. Continuously moist warm weather tends to produce excessive activity of the liver. An organ under functional strain is predisposed to go wrong upon slight provocation. A chill leads to congestion, and 'bilious fever', to use a popular name, ensues. It is exceedingly easy to become chilled in the tropics, far easier than in the North, because one is almost constantly wet with perspiration; in that condition a draft of air will precipitate disaster. Malarial germs are probably always present in the system to some extent, even in the cooler countries; where the malaria-carrying mosquito abounds, as it does in the tropics, even extreme care will not suffice to prevent inoculation. But if congestion be averted, and the bloodstream be kept pure, Nature may be counted on to protect the health. The white corpuscles are there for that purpose. This is no place for a layman's quasi-medical advice, but it is proper to emphasize my belief, based upon personal immunity during long experience in the swampy regions of Brazil, Eastern Peru, Colombia, and Central America, and upon like immunity on the part of many whom I have known, that rational hygiene will protect a northerner against the dangers supposed to lurk in southern countries. The malaria-carrying mosquito flies only at night and a mosquito-curtain will keep it out; attention to the diet will maintain the liver in working order; and thin clothing will keep the body from becoming overheated. Americans going to the tropics are prone to dress in clothing as inappropriate for the conditions as would be a pongee coat at Dawson in mid-winter. They promptly become overheated, cool off rapidly, and find their systems deranged in consequence.

In spite of the climate, Colombia will soon be overrun with American prospectors. In one sense it is not a 'poor-man's country'. The indigenous foods

are cheap, but imported goods are costly. Living is more expensive in Colombia than in the Western States, except during the boom-days of a Nevada mining camp. Furthermore, the foreigner has to pay for being a foreigner. It casts no aspersion upon the character of the Colombian to state this fact. It costs a man more to live in a strange city in his own land than it does in his native town; add to this difficulty the inconvenience of a language imperfectly understood, and the friction of customs divergent enough to offer no hope of familiar comforts, and the costs of living necessarily increase. General merchandise and manufactures cost more in Colombia than in the United States, hence outfitting should be done before departure for the South. Supplies, moreover, should be properly segregated for shipment and billing, to take advantage of the benefits conferred by the customs regulations. All machinery and supplies for mining and agriculture are admitted duty-free. To obtain free entry, however, a consular invoice must be obtained upon such goods. Colombian consuls are stationed at New York, New Orleans, San Francisco, and other ports. The consular fee for a single invoice (*factura*) of certain specified articles, which would include many of those required in an outfit for prospecting or for mine-examination, is \$9. An invoice for other goods valued less than \$200, costs \$18; from \$200 to \$500 the fee is \$24; and above \$500, it is \$30 for each \$1000 or fraction thereof.

Direct communication from New Orleans to Colombian ports does not exist. A transfer at Colón on the Isthmus is necessary. It is best to take the Atlas line from New York; on the west coast the Pacific Mail steamers from San Francisco land the traveler at Panama, the fare being \$120. From Panama to Buenaventura, the only important Pacific port of Colombia, the fare is \$32. From Colón, at the northern terminus of the Panama railroad, several steamship lines afford communication with the principal Colombian ports on the Caribbean Sea, namely, Cartagena and Sabanilla, the time being respectively 36 hours and 2½ days. A short railroad extends from Sabanilla to Barranquilla, the largest town on the Magdalena river, and another railroad, with a daily train-service extends from Cartagena to Calamar, a port on the river 1½ days journey above Barranquilla. Steamers leave Barranquilla on Mondays and Saturdays, and touch at Calamar. It is more interesting to enter the country through the magnificent harbor and quaint walled city of Cartagena. It is the only walled city in America, and its aspect is decidedly medieval. The only approaches to the great goldfields of the interior are by the Magdalena river from the Caribbean coast, or from Buenaventura to Cali on the west. The auriferous gravels are chiefly along the Cauca river. Ascending the Magdalena the best route is by way of Puerto Bérrio, whence a railroad has been built to Providencia, 30 kilometres (18½ miles) from the important city of Medellín. It is safer for a newcomer to go to a large centre like Medellín and strike out properly equipped from there, than to land at smaller ports on the river.

though they may be geographically nearer some of the gold deposits. The larger opportunities for prospectors lie along that part of the Cauca which is directly west of Medellín, and thence southward, up-stream, toward Popayán. The dredging ground lies chiefly along the lower reaches of the river, and deposits suitable for hydraulicking are more abundant farther south. It is claimed, moreover, that richer gravels exist in that direction, but that is not necessarily true, for the contribution of gold to the stream-gravels occurs throughout the extent of the high range which flanks the valley on the east. To reach the central and upper portion of the Cauca valley, a simpler, quicker, and cheaper route is to go through Buenaventura, from which wretched little port a railway, the Ferrocarril del Cauca, gives

Map of Choco, Colombia.

transport twice each week to Tocotá on the summit of the Coast Range—about 2800 ft. above tide. From Tocotá to Cali is only 30 kilometres, or about 6 hours' ride on horseback. Cali is a pleasant place, and salubrious, as is the entire Cauca valley from that point southward. It consists largely of open plains or savannas, with wooded areas and ravines. From Buenaventura access is also easy by launch or sailboat to Togoromá, the port at the mouth of the San Juan river, which leads up to the great gold and platinum fields of the Chocó. Launches afford communication from Togoromá to Noanamá, and small launches can even ascend as far as Istmina in the centre of the gold-bearing region. The goldfields of the upper Atrato are also conveniently reached by this route, as well as by steamers up that river from the Caribbean.

The outlook for gold mines on the upper reaches of the Magdalena river is promising. In that region exist larger opportunities for finding veins of gold ore than in the Cauca valley. On the great plateau of Bogotá are opportunities of another sort. Great saline and alkaline deposits exist, which have been only imperfectly studied. The famous emerald mines, which are Government property, are at Muso, a half day's ride from Chiquinquirá. A railroad is in operation from Bogotá to Nemocón, 68 kilometres in that direction, and is being extended to Chiquinquirá. A deposit of rock-salt, equal in size to those of Louisiana, exists at Zipaquirá a short distance from Nemocón. The railroad from Girardot, at the head of navigation on the Magdalena river, had for some time rested at El Hospicio, but within the last 30 days the line has been opened for traffic to Bogotá, and trains now run daily between that city and the river port. Steamers from Barranquilla or Calamar go as far as La Dorada at the foot of the rapids. A short railway transfers passengers and goods to Honda at the head of swift water, from which point another steamer continues the voyage to Girardot. Another modern transportation convenience consists in an automobile service from Bogotá to Belén de Cerinza in the Department of Santa Rosa. From this point a good trail leads to Pamplona and Cúcuta, near the Venezuelan frontier. From Cúcuta a good road exists to the Gulf of Maracaibo, the coffee of that region taking the Maracaibo route to the outer world.

From Puerto Wilches on the Magdalena is a short line of railroad extending in the direction of Bucaramanga which is nearly finished, and from the Caribbean port of Santa Marta, famous in history, is a railway to Ciénaga. Precious metals in notable quantity have so far not been found in that part of Colombia lying east of the Magdalena river, but coal, iron, petroleum, asphalt, and ores of lead and zinc are quite widely distributed.

According to the laws of Colombia foreigners may acquire and hold all classes of property, real estate, mines, ships, etc. Public lands (*tierras baldías*) may be freely taken up either by purchase from the Government, or by actual settlement and cultivation, in a manner similar to the method known as 'homesteading'. In like manner no distinction is made between Colombians and foreigners in the location of mining claims. The mining laws of the Republic are too extensive to be safely recapitulated. They constitute a special code (*Código de Minas*) of which translations can be obtained in the cities of Cartagena, Medellín, or Bogotá. The spirit of the country is liberality to the foreigner.

Note.—A map of Colombia will be found in the MINING AND SCIENTIFIC PRESS of February 6, page 217. Since that map was made the Republic has been re-divided for purposes of more efficient administration, into Departments, adding 22 new political subdivisions. Full data for revision of the map have not yet arrived, but references to Departments in the above article are in accordance with the recent change in boundaries.

DITCHES.

Written for the MINING AND SCIENTIFIC PRESS
By DOUGLAS WATERMAN.

In the following discussion on the most economic ditch-section, I assume, first, that the cost of the ditch is directly proportional to the amount of material excavated, and second, that the grade is not restricted by the topography, but by the resulting velocity of the water, which must be within safe limits for the material in which the ditch is constructed. These conditions are not often found in large irrigation canals, but apply generally to mining and to power ditches, which are usually constructed in a mountainous country, where any desired grade may be obtained, and of such a size that the excavation offers no mechanical difficulties. Under the above conditions the most economic ditch section is one in which

Where

and

Let

$r = \frac{X}{2}$

$r = \frac{\text{Area}}{\text{Perimeter}} = \text{Hydraulic Radius}$

$X = \text{Depth of Water}$

$Y = \text{Bottom Width}$

$Z = \text{Top}$

$\theta = \text{Angle of Slope}$

Then

$X = \sqrt{\frac{a}{\frac{2}{\sin \theta} - \cot \theta}}$

$Y = \frac{a - X^2 \cot \theta}{X}$

$Z = Y + 2 \frac{X}{\tan \theta}$

The proof of these relations may be found in any treatise on hydraulics.

The matter may be best illustrated by an example. For this purpose it will be assumed that a ditch is to be constructed having a capacity of 5000 miner's inches (125 sec. ft.); the velocity of the water to be 3 ft. per second, and the slope 1/2 to 1. From the relation $Q=aV$, the area of cross-section is found to be 41.7 sq. ft. Q is the capacity of the ditch in cubic feet per second, a the area, and r the velocity in feet per second; thus the values X , Y , and Z may be derived from the above formulae. A convenient diagram is shown in Fig. 1. The scale of the cross-section paper being logarithmic, the values of X , Y ,

and Z are represented by straight lines. Referring to this diagram it is found that, for an area of 41.7 sq. ft., $X = 5$ ft., $Y = 6$ ft., $Z = 11$ feet.

In Fig. 2 is shown a graphic method for determin-

ing the economic section of a conduit where the radius of the inscribed circle is known. The flow of water is a maximum, and the amount of excavation a minimum when the section has the least wetted perimeter. It is obvious that for a given area, the circular section has the least wetted perimeter. But conduits as usually constructed have a trapezoidal cross-section, in which case the circumscribed trape-

zoid gives the least wetted perimeter. Values of R in terms of the area are given for slopes ranging from vertical, to 1 1/2 to 1. The area being given by

Q

the relation $a = \frac{Q}{V}$, R for any slope may be taken

from the diagram.

Describe a circle to scale with this radius. Draw a line through the centre, and a parallel tangent to the circle. Lay off the slope as shown by the dotted triangles, and draw tangents to the circle. This will give the economic section. It will be seen that for a rectangular section, the width is twice the depth.

It now remains to determine the grade, which is found from Kutter's formula:

$(1) \quad V = C\sqrt{r} \cdot \sqrt{S}$

$(2) \quad \sqrt{S} = \frac{V}{C\sqrt{r}}$

$(3) \quad C = \frac{\frac{1.49}{n} + \frac{41.65 + \frac{0.00281}{S}}{1 + \frac{n}{\sqrt{r}}}}{\frac{41.65 + \frac{0.00281}{S}}{S}}$

$V \text{ is given} = 3 \text{ ft per sec.}$

$\sqrt{r} = \sqrt{\frac{X}{2}} = \sqrt{2.5}$

n = coefficient of roughness, which from the table is assumed to be 0.035.

S —the slope or grade of the ditch—is unknown, but may be found by the method of approximation.

To obtain a first approximation for C in equation (3), the terms involving S , being small, may be neglected. Giving C this value in (2) we obtain a value for S , which substituted in (3), gives a closer approximation for C ; the final value of S is derived from equation (2).

First approximation... $C = 48.67 \quad S = 0.00152$

Second approximation... $C = 48.84 \quad S = 0.00153$

Hence the rod-change for 25-ft. stations is 0.038 ft. Owing to the uncertainty attending the choice of a proper coefficient of roughness such refinement is un-

that some idea may be formed of the values of V and n as applying to mining ditches in California, I have extended the table given by Bowie in his 'Practical Treatise on Hydraulic Mining', to include the coefficient of roughness and the velocity. As the coefficient

taken to protect the flumes from forest fires. In digging a ditch it will be found that the ground in many places is loose and porous. Clay is the best material with which to puddle a ditch, and workmen should be instructed to save suitable material for

cient of roughness is based upon the quantity of water delivered, it allows for seepage and other losses throughout the length of the ditch.

A favorable position for the waste-gate is one where the bedrock is exposed or near the surface, as

this purpose. Small charges should be used in blasting where there is danger of shattering the bottom or lower side of the ditch.

Giant powder containing 60% nitro-glycerine will

Ditch Building in California.

there is then little danger of undermining the ditch. The waste-way should be built to afford ample protection of the banks. In a timbered country, where wind-falls are always to be expected, the slopes should be cleared of brush and trees for a distance sufficient to prevent clogging of the ditch or injury to the banks. The greatest precaution should be

be found better adapted to ditch construction than a lower grade explosive, as the relative shattering effect of a 'quick' powder is much less than with one incapable of a high degree of detonation. Also, in order to insure such effect a high-force cap, not less than 5X, should be employed. A half cartridge will break a 14-in. burden perfectly.

CHEMISTRY OF THE BROMO-CYANOGEN PROCESS.

Written for the MINING AND SCIENTIFIC PRESS
By S. H. WORRELL.

In 1894, Sulman and Teed, two English metallurgists, obtained a patent for a process of gold extraction involving the use of bromo-cyanogen with the regular cyanide process. They claimed for their process greater rapidity and higher percentage of extraction in the case of complex ores than could be obtained with the McArthur-Forrest method alone. In Vol. III. pp. 202-224, of the Transactions of the Institution of Mining and Metallurgy, Mr. Sulman gives an extensive list of results obtained on complex ores. These results were favorable to the process, which under the name of Diehl, has been successfully applied and now seems to be a well established method of gold extraction.

The only late contribution on the subject, so far as the writer has been able to find, is the article by E. W. Nardin which appeared on October 31, 1908, in the MINING AND SCIENTIFIC PRESS, to which the reader is referred for a detailed statement of the technical application of the process. In Vol. I of the Proceedings of the Chemical and Metallurgical Society of South Africa (1894), there appears an interesting discussion of a paper by H. L. Sulman, who believed that he had found in bromo-cyanogen a substitute for the slowly acting oxygen of the air necessary in the McArthur-Forrest process. The reaction underlying the latter, called Elsner's equation, is as follows:

Mr. Sulman gives the reaction for his process as follows:

Not only Mr. Sulman's process, but his reaction as well, seem to have met with a reception more sarcastic than friendly, judging from the discussion which followed. J. E. Clennell did some work on the process in an attempt to solve the reactions occurring and gave the following as suggesting what happens:

However, he did not wish to be understood as asserting positively that the above is the reaction in the case. He experimented qualitatively only on KCN and BrCN solutions in which gold was not present at all.

The article by Nardin gives the Sulman equation in explanation of what is, as the author puts it, "supposed" to happen. A knowledge of what really happens seems desirable, and so far as I have been able to ascertain, it has never been determined. Here-with follows a brief outline of some work done with this end in view.

Chemically pure BrCN was first prepared as follows: (Ber. 1896, Vol. 29, pp. 1822-25). A solution of 65 grams KCN of 98% in 120 c.c. water was cooled to 0° C. and added drop by drop with shaking

to 150 grams bromine covered with a little water. The temperature of the bromine should not be allowed to rise above 30° C. Add the KCN until the Br becomes yellow. Then distill the pasty mass at 65° C. This will give white crystals of c.p. BrCN. The crystals so prepared were placed in solution in water. This solution, of about 2%, was found to be stable.

Finely divided gold, purified by repeated precipitation with oxalic acid, was used in all the work. The KCN was 98 per cent.

To a measured quantity of 0.5% solution of KCN, was added the finely divided gold in large excess and air was drawn through the solution from six to eight hours, for the purpose of keeping the gold agitated and supplying the necessary oxygen to carry out Elsner's equation. The solution was then filtered and the gold washed. The solution so obtained was made up to 500 c.c. and an aliquot part taken to determine the amount of KCN consumed. This was done by titration with silver nitrate. The remainder was treated with sulphuric and oxalic acids to precipitate the gold. The precipitate was then collected on filter-paper, dried, burned, the residue being fused with mixed alkali carbonates to which had been added a little flour and sheet lead. The fused mass was leached with water and the lead button cupelled for gold. Similarly, to another measured quantity of the KCN solution were added the gold and a measured quantity of the BrCN solution, the whole being then agitated intermittently from two to four hours. The amount of BrCN added in every instance was such that it contained less cyanogen than was present in the KCN solution taken (Sulman's suggestion). The solution was then made up to some definite quantity, generally 500 c.c., as in the first case. Then 250 c.c. was taken for the determination of gold and 100 c.c. titrated for the cyanide consumption.

A statement of some results is appended: In the first case the solution was approximately 0.5%; in the second case a solution slightly different was taken. In the first case 50 c.c. was taken, and in the second 250 c.c., made up to 500 c.c. in each instance:

	KCN consumed, c.c.	Weight of gold in aliquot part, grams.	Total weight of gold, grams.	Weight of gold per c.c. KCN consumed, grams.
First solution, with air....	26	0.0252	0.0504	0.00193
First solution, with BrCN...	37	0.0680	0.1360	0.00370
Second solution, with air...	90	0.0830	0.1035	0.00115
Second solution, with BrCN.	86	0.1018	0.2036	0.00236

From the above it will be seen that twice as much gold is dissolved with the same amount of KCN when bromo-cyanogen is used instead of oxygen of the air. In explanation of the above the following reaction is suggested:

the proportions in Elsner's equation being

According to *Bull. de Soc. Chem.*, Paris, 29-416 (1st

series), $\text{KAu}(\text{CN})_2$ forms absorption-products readily with the halogens, which explains the formation of the $\text{AuCN} \cdot \text{Br} \cdot \text{KCN}$ suggested above.

In closing, it may not be amiss to call attention to the fact that the simple addition of bromine to cyanide solutions when treating ores cannot be substituted for the bromo-cyanogen process in practice, for the reason that to give a good yield of BrCN the temperature must be near freezing, otherwise oxidation products and consequent loss of Br and KCN will result. Also for every molecule of $\text{KCN} \cdot \text{AuCN}$ present already in the solution, there is a probability of loss of a molecule of bromine by absorption, and thereby temporarily, if not permanently, putting it out of commission without having accomplished its intended purpose.

CALCULATION OF HEAT CONDUCTIVITIES.

By CARL HERING.

*In calculating the heat losses by conduction through the walls of furnaces made of several materials, as, for instance, firebrick on the inside and infusorial earth on the outside, it is necessary to know what the heat conductivity is for firebrick between two high temperatures. The calculation is limited to the ranges given in the usual text-book tables. If, for instance, the heat conductivity for firebrick is given as 0.0014 as a mean from 0° to 500°, and 0.0031 as a mean from 0° to 1300° C., it is possible to calculate correctly the corresponding figure between the two given high temperatures, 500° and 1300°. These particular values are in the c.g.s. system and mean the calories per second which will pass through 1 cm. of the material, 1 sq. cm. in section, for a difference of 1° C. between the two surfaces.

Let k be this heat conductivity for the lower range of temperature t , and K the corresponding figure for the higher range T ; let t' and T' be the two maximum temperatures of the ranges t and T , respectively; and let H represent the heat in calories per second passing through a body. For 1 cu. cm.

$$H = kt.$$

Assume another piece of the same material, also 1 cm. in cross-section, and of such length, L , that it will conduct the same quantity of heat, H , when its ends have the temperatures 0° and T' , for which the mean conductivity is K . For this rod

$$H = \frac{KT}{L},$$

but as the heat-flow H , is by definition the same in both, it follows that

$$(1) \quad kt = \frac{KT}{L}$$

This may be represented diagrammatically by a cube and a parallelopiped, referring the heat conductivity to unit volumes. Now, let x be the quantity desired, namely, the mean conductivity between the two higher temperatures t' and T' . It can be shown by diagrams that, as the flow of heat is the same in both, it necessarily follows that the longer rod will

have a temperature of 500° at a distance of 1 cm. from the cool end, because that last centimetre must be under precisely the same conditions as the cube above, in order that the flow of heat be the same. Hence, it follows that there will be a fall of temperature from T' to t' over a length of this rod equal to $L-1$; and as the heat flowing through this portion is the same as through the whole rod, it follows that

$$(2) \quad H = x \frac{(T' - t')}{L-1} = kt$$

Eliminating L from equations (1) and (2) and solving for x gives the desired quantity

$$x = \frac{KT - kt}{T' - t'}$$

Applying this by illustration to the above data for firebrick, it will be found that

$$x = 0.00416,$$

which, therefore, is the mean heat conductivity of firebrick for the range 500° to 1300° C.

Incidentally, it may be of interest to solve equation (1) for L , and it will be found to be 5.76 cm. A diagram will show graphically what a large amount of firebrick is necessary to reduce the temperature in the walls from 1300° to 500° (namely, 800°), and what a relatively small thickness is required for the remaining 500°. This, of course, is due to the fact that firebrick rapidly loses its insulating properties at high temperatures. It shows how important it is to have as thin a layer of firebrick and as thick a layer of infusorial earth as possible, the relative amounts depending upon the maximum temperature at which the high insulating material will retain its good quality.

Volumetric estimation of potassium with cobalt nitrate, is a method worked out by Drushel (*Am. J. Sci.*, XXIV, 433). The solution, which should contain not over 0.2 gm. K_2O , and should be free from NH_4 salts, is treated with an excess of sodium cobalt-nitrate, and evaporated to pastiness on the water-bath. Cool, and add 50 to 100 c.c. cold water, and stir well to dissolve the excess of the precipitant. Wash a few times by decantation, using cold water, and then transfer to a Gooch filter. Dilute a measured excess of standard permanganate to about ten times its volume and bring to a boil. Introduce the filtering felt and finally the Gooch, and stir well. After 5 or 6 minutes add 5 to 25 c.c. of H_2SO_4 (1:7) and allow to stand a short time. Then run in an excess of $\text{N}/10 \text{ H}_2\text{C}_2\text{O}_4$ solution from a burette, heat until colorless, and titrate with the standard permanganate. The total amount of permanganate used, less that required for the $\text{H}_2\text{C}_2\text{O}_4$ introduced, is calculated to K_2O . If the permanganate is exactly $\text{N}/10$, 1 c.c. equals 0.000856 K_2O . The $\text{N}/10 \text{ H}_2\text{C}_2\text{O}_4$ is made by dissolving 7.1066 gm. pure recrystallized $(\text{NH}_4)_2\text{C}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$ in water, adding 50 c.c. strong H_2SO_4 , and diluting to one litre. Ca , Mg , or P_2O_5 do not appear to interfere. Barium Sr in the solution seems to give high results.

The Western Pacific tunnel under the Pequop mountains in Elko county, Nevada, has recently been completed. It is 5657 ft. long.

CHURN-DRILL SAMPLING.

Written for the MINING AND SCIENTIFIC PRESS
By W. E. THORNE.

The best practice today is to drive the pipe 1 ft. ahead and then drill 10 or 11 in. In discharging material from the pump into the sample-box the thin portion is allowed to run out, and then the panner places his pan under the hole in the pump,

Fig. 1.

and catches the coarser part of sample. As many pumpings for each foot of sample are made as the panner thinks is required to get the amount of material that should be in the sample. Usually two or three pumpings are enough. The character of material governs, for in some gravel a pumping will

Fig. 2.

yield a pan three-quarters full, while in other cases it will be less than half full. A core is always left in the pipe; the depth of this core must be determined by experiment; it should be enough to hold back the water on the outside of the pipe and prevent

it breaking in with a rush. If it does that some gold may be carried in from outside, and the sample will show a value in excess of the truth. After that the drill is lowered into the hole until it reaches the core; the drill-runner notes the height of the core, and calls it to the panner, who records it in the 'log.' Then the pipe should be filled with water to the same level as the ground-water outside; this is to prevent an inrush of water when the core is pumped down close to the cutting edge of the drive-pipe. The core is loosened by the bit, and the pipe is driven another foot. If the core is not loosened in some cases it

Fig. 3.

becomes so solidly packed that on driving, the result is like driving a pile, and part of the gravel, carrying gold, is forced to one side.

A flat rock struck by the shoe and forced ahead

Fig. 4.

will also drive the gravel to one side. This should be detected by the driller. The coarse material is panned in a tub, and the size and number of 'colors' found are recorded. The pannings from the tub, and the sample in the sample-box, go through the rocker, and the concentrate from the rocker is again panned,

so that 90% of the sample is panned at least twice. When the hole is finished the gold in the pan-concentrate is amalgamated, and the amalgam is placed in a small phial and taken to a laboratory, where it is treated with nitric acid to remove the mercury. The gold is dried, annealed, weighed, placed in a phial, marked and filed for future reference.

In one case in California, in drilling loose ground, the drill-runner had instructions to carry from 1 to 2 ft. of core. As a result this core would become solid at times, and so much of the material was driven to one side that the drill-tests showed a low gold-content, and the property was 'turned down.' Later others tested the ground by shafts. The returns were good, and the property was bought, a dredge built, and it has proved profitable.

In Fig. 1 it is shown how a shoe sometimes strikes on a boulder. I have found in medium loose gravel that the boulders will be driven ahead as shown in Fig. 1: No. 1 boulder will have been forced down, and to one side: the gold immediately above and on each side will follow down, and be carried to one side, while a part of it will be lost from the sample. Boulders No. 2 and 3 will be driven ahead. In some cases No. 3 will also be driven to one side, and a part of the gold with it. Sometimes No. 2 and 3 will be broken, and finally come up into the pipe, causing too high a gold recovery. If either of these cases occur in the pay-streak, it will cause an appreciable error, as a difference of one milligram of gold per foot in depth means over 5c. per cubic yard. I have had test-shafts sunk on drill-holes, where the drill-log showed fine gravel all the way down, when in fact there were boulders from 12 to 14 in. long in the material. As revealed by the shaft these boulders had been driven down and to one side, carrying a part of the gold with them, as returns from all the gravel taken from the shaft showed a value as much as 60% higher than the drill-test. This error was partly caused by using a rock-bit in the work, and in not keeping it sharp. This resulted in the bit becoming rounded as shown in Fig. 2 and 3.

In some sampling which I had done in Colorado a few years ago during two working seasons, two drills were running during the first season, a Keystone No. 2 and a Clipper No. 2. The drill foreman was well recommended, so but little attention was paid to the work. On going over the results and sampling by shafts I found that the results were over 100% too high. The foreman and the crews were dismissed, and two new crews put on. Instructions were given that more care must be used, but not to 'lead the shoe' except where driving could not be done without it; then to run the bit ahead just enough to break the boulder so that the pipe could be driven. One of the main sources of error on this work, as shown by testing with shafts, proved to be that seen in Fig. 4. After the bit had cut or broken the boulder, the shoe would strike it, as shown. If the bit had been leading the shoe, in attempting to drive it, the gold around a part of this boulder would get into the hole, causing an excess. After the first season's drilling the clean-up showed

in the sluices nowhere near the amount of gold revealed by the drill-returns; accordingly, before the next season's hydraulicking began, I had the ground re-drilled just ahead of the sluices, five holes to each acre. At the end of the second season's clean-up the returns were 9.8% above the drill-test. This was caused by the length of the sluice, which was some 1200 ft., so the loss was small. If I had used a short line of sluice, or a dredge, I doubt if the saving would have reached 95% of the drill-return.

No property should be considered proved by a drill alone; it should be checked by shafts. While the drills may show clay, cemented gravel, the kind of bedrock, and the like, they are not reliable in indicating the size of boulders, nor can they be absolutely trusted in the gold indicated. Drilling is cheaper and more rapid, but, after a preliminary examination of a property, if it be considered worth prospecting it should at least be well done, and it cannot be well done without a few shafts.

It may appear to the layman that these errors would balance each other, but they will not, because no two deposits are exactly the same, and that which causes an error in one deposit may not occur in another.

New concrete will not retain oil-paint because of dampness, and the presence of caustic lime. Time and nature will remove these objections, the carbonic acid of the air neutralizing the lime, but we shall hardly be allowed to wait for it. Acid will certainly do away with the caustic lime, but the remedy is about as bad as the disease, the salts of lime which are formed being either highly hygroscopic, like calcium chloride (CaCl_2), or the action being too superficial. After exhaustive trials Fred. J. Bosse has worked out the following method as the only one which will satisfy the needs for a paint on concrete: Dissolve 10 lb. carbonate of ammonia in 45 gal. water and apply with a brush; or make the solution weaker and give several coats, or apply as a spray. The following reaction takes place:

The ammonia which is liberated will evaporate, and the calcium carbonate which has been formed is perfectly insoluble and will become dry and hard in a short time. On the surface thus prepared ordinary oil paint may be applied. This process will be found convenient, cheap, and efficient.

The controversy between the Calumet & Hecla Mining Co. and the Osceola interests has been settled by an agreement whereby the Calumet & Hecla will absorb the Bigelow properties, including not only the Osceola but also the Tamarack, Ahmeek, Seneca, Laurium, and one third of Isle Royale. A decision by the Court of Appeals at Cincinnati recently confirmed the right of the Calumet & Hecla to vote the Osceola stock, of which the C. & H. owns 20,000 shares, and holds proxies for 25,000 more. It is understood that the transaction involved a transfer of 125,000 shares of stock at a price aggregating \$8,000,000.

COMPANY REPORTS.

MAZUMA HILLS.

This is the principal company operating in the Seven Troughs district, near Reno, Nevada. The full name is Mazuma Hills Mining Co. According to the second annual report, for the year ending December 31, 1908, the output was 2474 tons, worth \$114,092. The profit was \$25,001. John Harnan is president and J. T. Hawkins is engineer.

DALY-JUDGE.

According to the annual report of the Daly-Judge Mining Co. for the calendar year 1908, the receipts were \$285,570, of which \$14,166 was for zinc middling. The balance on hand is \$131,997, this sum having increased \$4342 during the year. Extraction of ore cost \$2.77 per ton and concentration 86 cents per ton. The shaft is 1650 ft. deep. E. W. Durfee is superintendent. The mine is situated at Park City, Utah, but the company is controlled at Cincinnati, Ohio.

MOUNT MORGAN.

The report of the Mount Morgan Gold Mining Co. for the half-year ended November 30, 1908, shows a total revenue of £507,239, as against an expenditure of £375,410. The profits amount to £131,829, from which two dividends of 5% have been declared, absorbing £100,000. This great gold mine is now an important producer of copper; during the six months under review 3272 tons of blister copper and 230 tons of copper precipitate were obtained from the 222,793 tons of ore mined. The average gross price obtained for the copper was £59 3s., compared to £65 18s. realized in the preceding half-year, irrespective of gold contents. The yield of gold was 84,037 ounces.

FIRST NATIONAL COPPER.

The First National Copper Co. is the holding company controlling the Balaklala Consolidated Copper Co. Thomas W. Lawson is president of the first and Thomas J. Barbour is president of the second. R. T. White is manager at the smelter and R. N. Bishop manager at the mine, in Shasta county, California. The first annual report, for the year ending December 31, 1908, shows that the capital stock of the Balaklala was purchased for \$1,500,000 and then the operating company was organized with a capital of \$10,000,000, besides \$750,000 in bonds. During the year the mine was in operation for 60 days and the smelter for 52 days. The ore developed is stated to average 2.7% copper, 0.025 oz. gold, 0.75 oz. silver per ton. The capacity of the plant is 1250 tons per day. Costs of mining averaged \$2.42, and smelting, \$2.92 per ton. The maps accompanying the report are examples of poor draftsmanship. Of the 24,943 tons smelted, 15,960 came from the Balaklala mine, 7286 from the Trinity, and 1697 tons was custom ore. The average slag analysis is given as 0.19% copper, 40.9% SiO₂, 37.5 FeO, 9.9 CaO, 8.1 Al₂O₃, and 2.5 ZnO. Coke forms 5.9% of the total burden and 7.58% of the weight of sulphides.

BRITISH COLUMBIA COPPER CO.

The above-named company, with mines in the Boundary Creek district and elsewhere, and a smelter at Greenwood, B. C., produced 5,767,355 lb. of copper in the fiscal year ending November 30, 1908. The ores also yielded 13,597 oz. gold and 58,204 oz. silver. The proceeds from shipments of metal amounted to \$1,086,635, to which sundry profits from other sources added \$13,324. A net profit of \$200,483 was realized. The authorized capital stock of the company is \$3,000,000, in \$5 shares, of which 503,000 shares have been issued to date. The smelter is equipped with three blast-furnaces and two stands of converters. The material treated during the year was 312,471 tons of ore from the company's mines, 4829 custom ore, 3846 converter slag, and 281 tons custom matte. Total cost of producing refined copper, including expense of marketing, was \$2.63 per ton of ore handled, or 9.996 cents per pound of copper, after crediting expenditure with the gold and silver produced. The report claims large additions to the ore-reserves, but measured quantities are not given. This is a serious omis-

sion, as no means of estimating the future possibilities of the mines are furnished. The record of development carried forward is given in the most general terms, and the absence of maps renders the information of no value in elucidating the situation. The company makes a favorable financial showing, which is especially commendable, in view of current market conditions. It would have added to the value of the statement to have supplemented it with more data concerning the mines and available ore-supply.

GUGGENHEIM EXPLORATION CO.

The annual report covering the calendar year 1908 shows liabilities and assets as follows:

Capital stock	\$22,000,000
Bills and accounts payable	1,003,531
Surplus	13,643,689
Total liabilities	\$36,647,220
Treasury stock	\$ 1,319,900
American Smelters Securities Co. (A)	13,860,000
American Smelters Securities Co. (B)	199,890
American Smelters Securities Co. Common	1
Other properties and investments	17,589,487
Furniture, fixtures, and equipment	7,706
Bills and accounts collectable	2,083,436
Cash and demand loans	1,586,800
Total assets	\$36,647,220

AMERICAN SMELTING & REFINING CO.

An interim statement has been issued to the stockholders of the assets and liabilities on October 31, 1908, and earnings for the first six months of the fiscal year. These figures show a profit of over 8% per annum on the common stock. Daniel Guggenheim, the president, states: "The business and earnings of the company declined from the beginning to the end of the fiscal year ending April 30, 1908. Since the beginning of the present fiscal year, however, the earnings have been gradually improving month by month. The company has not, in the past, issued reports to the stockholders with reference to the business of the company oftener than at each annual meeting, principally for the reason that it is both difficult and expensive to accurately cut off the business oftener than once a year, on account of the large value of precious metals in process of smelting and refining. The directors believe, however, that the desire of the stockholders for accurate reports as to the operations and profits of the company as often as is practicable is warranted."

The profit and loss statement for the six months ending October 31, 1908, shows:

Net earnings from operations	\$ 3,917,684
Construction and improvements	75,923
	\$3,841,761

DIVIDENDS.

Preferred, 3½%	\$1,750,000
Common, 2%	1,000,000— 2,750,000
Net surplus to profit and loss	\$ 1,091,761

ASSETS.

Property	\$ 86,845,676
Investments	2,858,617
Metals (refined value)	18,218,785
Material	1,249,561
Cash and demand loans	8,629,550
Total	\$117,802,184

LIABILITIES.

Capital stock	\$100,000,000
Bonds	349,000
Net current liabilities	804,645
Unearned treatment on metals in process	2,148,559
Profit and loss	14,499,979
Total	\$117,802,184

Ore-Bedding System.

By E. H. MESSITER.

In the MINING AND SCIENTIFIC PRESS of October 26, 1907, I described the new method of blast-furnace charging utilizing the Robins Conveying Belt Co.'s ore-bedding and reclaiming devices. This system was installed at the works of the Cananea Consolidated Copper Co. On July 11, 1908, the plant went into regular operation.

The re-construction of the Cananea smelter is interesting in many ways. In fact, it may be said to be unique, both as to method and results. Instances in which a furnace-house, a power-house, or a converter-house, laid out at first for a small capacity, has been brought up to the highest efficiency after it had outgrown itself are not rare; but it has seldom been possible in the past to find a plant that has grown from two small furnaces to eight large ones and to bring the whole plant up to date. As soon as we cease to deal with the separate parts by themselves, the question of the handling of material becomes the great obstacle. Formerly

View Across Ore-beds; the Ore-bedding Tripper is Dropping Ore on the Bed in the Foreground, While the Reclaiming Machine is in Operation on the Far Bed.

the question of the transmission of power was another difficulty, but the use of electricity has taken care of that.

At Cananea not only have the individual parts of the smelter been put into admirable shape, but the whole works has acquired a degree of efficiency that has probably placed it at the head of its class. The new ore-bedding system is the one feature that has made the combined result possible.

The use of the belt-conveyor does for the transportation of material almost exactly what the use of electricity does for the transmission of power. Distances, differences of elevation, or relative positions of buildings, otherwise seriously disadvantageous, become of little consequence. This ore-bedding system makes the use of the belt-conveyor practicable in the compounding and handling of blast-furnace charges.

The cars that bring the ore and flux to the smelter are unloaded into receiving-bins of moderate capacity, the chutes from which deliver the material to the first belt conveyor of the series. These bins are only large enough to permit them to serve as an equalizer between the railroad and the belt-conveyor. They occupy a sufficient length of track to

accommodate as many cars as must be unloaded at one time. On the way from the receiving-bins to the ore-beds the conveyor line is broken in order to pass the ore through crushers and samplers. Screens can be introduced with equal facility to divert the fine ore for separate treatment.

Over each bed there is a belt-conveyor equipped with a high-speed tripper, which distributes the ore continuously over the whole length of the bed. In this way the pile is made of uniform composition and physical character throughout its length. After the bed has been brought to the composition desired for the furnace-charge, the reclaiming machine attacks it from one end and sends the charge over another series of conveyors to the furnaces. The machine removes material from all parts of the cross section of the bed in a continuous manner. The remarkable results of the process are largely due to the uniform accuracy of the mixture delivered by the reclaiming machine.

The moving parts of the reclaiming machine consist of a harrow covering the whole face of the bed and gently moved back and forth, a chain of plows running on a steel plate at the bottom of the machine, and gearing arranged to advance the machine automatically into the bed. The reclaiming machines have been found to operate with great regularity on account of their extreme simplicity. From measurements of the wearing parts, after handling a large tonnage it is thought that the total cost of repairs on the machines will be between one-fifth and one-quarter cent per ton. The last conveyor deposits the charge in bins placed over the furnaces. From these it is drawn into measuring hoppers and from them falls directly into the furnace.

The accompanying photograph shows the appearance of the ore-beds during regular operation.

The first cost of three ore-beds of 10,000 tons capacity each, including reclaiming machines, is about one-half the cost of steel bins of the same capacity or three-quarters of the cost of timber bins. In operation, direct labor is eliminated. The cost of handling per ton is far lower than any previously realized with the exception of a small number of plants where there are only one or two classes of ore on the charge and where only one or two days' supply of ore is provided within reach of the furnaces.

The performance of the blast-furnaces is greatly improved. Irregularities calling for frequent changes in the charge for individual furnaces or all the furnaces of a battery, are now almost unknown. Charges of composition formerly impossible are easily smelted on account of the intimate mixture of the ingredients and the absence of unbidden chemical or physical variations. It is to be expected that when applied to lead smelting, the metallurgical as well as labor-saving advantages of this system will be even more striking than in copper practice.

Commercial Paragraphs.

THE MURRAY IRON WORKS Co., Burlington, Iowa, builders of Corliss engines and tubular, internal-fired, and water-tube boilers, are open for a San Francisco correspondent.

A. G. KIRBY and W. H. SHEWAN are erecting an ore-testing plant at Reno, Nevada, which includes equipment for amalgamation, concentration, and cyanidation.

THE HENDRYX CYANIDE MACHINERY CO., of Denver, Colo., has recently received an order from the Tominil Mining Co., of Mazatlan, Sinaloa, Mexico, for a complete 50-ton mill, which includes crushers, rolls, tube-mills, agitation and filtration in Hendryx combination agitator and filter, and precipitation with zinc-dust. The cyanide equipment for 150-ton plant has also been sold to the Aguacate Mines Co., of New York, whose property is in Costa Rica, and a 20-ton plant to the Twin Butte Mining Co., of Clarkson, Washington.

On January 29, during the week the Sales Organization of the WESTERN ELECTRIC Co. held its conference in Chicago, some of the old employees of the Chicago Organization gathered at luncheon at the Grand Pacific Hotel. Those who attended, and the dates they entered the employ of the

company, are as follows: E. W. Bennett, 1874; J. C. Cannon, 1877; F. B. Uhrig, now Western district supervisor of the company at Kansas City, 1881; D. L. Harmon, now a banker at Indiana Harbor, Ind., 1883; C. D. Wilkenson, manager of the Minneapolis house, 1886; Wm. Carpenter, of the Walworth & Neville Mfg. Co., who entered the employ of the Western Electric Co. in 1887; Rolo C. Hearsley, 1888; and E. S. Holmes, now manager of the Indianapolis house, 1890.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

GOLD: ITS GEOLOGICAL OCCURRENCE AND GEOGRAPHICAL DISTRIBUTION. By J. Malcolm MacLaren. Ill., pp. 687, 8vo. London: The Mining Journal. 1908.

This is an excellent book. The author, in his preface, apologises for adding "one more treatise to the literature of the study of ore deposits," but he need not have done so. Books so carefully prepared by authors as well equipped to write them are not numerous, even in economic geology. By his scholarly training, by his wide experience, and by his keen observation, Mr. MacLaren is well fitted to write a book on the geology of ore deposits valuable for gold. He has performed his task well, giving a book that every student will like to read and every mining engineer to possess. Part I is devoted to the general relations of auriferous deposits; this begins with a discussion of fundamental geological principles and then describes the known mineral compounds of gold. Then comes a classification of deposits into provinces, with a description of the principal goldfields of the world, followed by a compendium of observations relating to secondary enrichment, concentration in ore-shoots, and other matters keenly interesting to the miner. Part II is entitled "The Geographical Distribution of Gold". This is a world-wide survey of the subject, and presents a useful summary of data concerning gold deposits in every region that is the scene of profitable mining. This part of the volume is well illustrated with sectional drawings of important lodes and by maps of many of the chief goldfields. The author is honest in reference and courteous in quotation, as becomes a scholar. He also exhibits the true scientific spirit in making no effort to speak conclusively concerning problems as to which conclusive evidence is lacking, contenting himself—and the reader—by stating the facts and as much theory as is warranted. The book is well printed and is a credit to the publisher.

LABORATORY EXPERIMENTS IN METALLURGY. By Albert Sauveur and H. M. Boylston. Small 4to., pp. 73, index. Cambridge, Mass. Published by the authors. 1908. Price \$1.25.

The primary intention of this volume is to serve as a guide for instruction in laboratory practice; indeed, it would seem that its purpose were to inculcate method rather than to cover any field comprehensively. The illustrations of procedure to insure conditions leading to accurate results will undoubtedly point the way to similarly trustworthy methods in experiments not here specifically described. Nevertheless, a more extended treatise would be generally welcome, for such details of procedure are precisely what the text-books usually omit. For example, the volume before us will be of service to anyone having to do with calorimetry and pyrometry. There is a great deal of reckless pyrometry practised by men who should know better, but who have not had the minute details of procedure presented to them so that accuracy within the limits of instrumental error might be attained. The details given by Sauveur and Boylston on the use of the Mesuré & Nouel optical pyrometer, the Le Chatelier, and others, will be valuable. Also the method of determination of melting points is important. The work gives the procedure in proximate coal analysis, and then presents the heat treatment of steel in considerable detail. In that connection the ground covered is: magnetic properties occurring

at the thermal critical points; relation between critical points and hardening power of steel; brittleness produced by hardening; effect of sudden quenching of high-carbon steel; effect of hardening on ductility, elasticity, and transverse strength; influence of variation of carbon-content; influence of nature of quenching bath; tempering of hardened steel; effect of annealing on cold-worked steel; effect of heat on grain of steel. It will prove suggestive and helpful as a laboratory assistant to those having in hand researches in fuels and steels.

MAP OF A PART OF NORTHERN MEXICO. Compiled by H. A. Horsfall. Four sheets, 9 by 12 in.; scale, 1 cm. = 20 kilometres, or approximately 1 in. = 32 miles. Price \$2.

This compilation is exceedingly useful. It gives the most recent development of railroads and wagon-roads, and also shows trails throughout the area covered. In the details of railways and roads we have detected no errors. As much cannot be said for place-names, which have not been carefully edited. For example, on Sheet No. 3, we find Carbera for Cabrera, and Bacubrito for Bacubirito; on Sheet No. 4, Guadalupe de la Reys for Guadalupe de los Reyes, Conelas for Canelas; on Sheet No. 1, Tomochi for Tomóchic; and nearly all accents and tildes are omitted. Incidentally we may point out that if one should attempt to go by trail from Tamazula to Tepehuanes by the route indicated he would be three days longer than necessary on the road, and would have a sorry time of it; it would also be risky for a stranger to try to travel from Guadalupe y Calvo to Bacubirito, for instance, with no better guide than is here given. By these tests the trace of trails is not reliable. Otherwise the map seems in the main admirable, and it is certainly the best that can be obtained in compact form for the region covered, which stretches from Sierra Mojada and Presidio de San Vicente in the east to Guaymas and Mazatlán in the west.

COMPENDIUM OF USEFUL LEGAL INFORMATION FOR BUSINESS MEN. By B. A. Brennan. 16mo., pp. 571. New York. John Wiley & Sons. 1908. Price \$5.

A practical succinct statement of the common obligations and powers under the law with regard to the ordinary business of life is a welcome addition to every man's library. No book can supersede the services of an attorney, but such a work as this will perform a useful service in warning the laymen of dangers and perils where, with the confidence of half-knowledge, he might have proceeded along lines that would have led to difficulties. The introductory chapters on contracts, sales contracts, property, deeds, mortgages, acknowledgments, power of attorney, and the like, will throw light on these subjects for the uninitiated. Of special importance is the extensive chapter on the Negotiable Instruments Law. Details of State law on ordinary commercial matters are given in considerable detail.

Catalogues Received.

THE J. GEO. LEYNER ENG. WKS. CO., Littleton, Colo., is distributing its Bulletin No. 1001, which is a series of reprints from the technical press dealing with modern methods of driving tunnels in hard rock. Numerous items on cost data are given.

THE WESTINGHOUSE ELEC. & MFG. CO., Pittsburg, Pa., is distributing an exceedingly attractive catalogue of fan motors. The cover is printed in colors and is a distinct departure from the usual machinery catalogue style. Complete dimensions and prices of all styles of fans are given.

THE ALLIS-CHALMERS CO., Milwaukee, has recently issued a list and index of the different bulletins and instruction books published by the company. It includes 187 pamphlets describing and illustrating prime movers of every description, electrical apparatus for alternating and direct current, pumping machinery, mining machinery, crushing and cement making machinery, flour mill machinery, and saw mill machinery.

EDITORIAL.

WE are glad to state that Mr. H. Foster Bain, recently State Geologist of Illinois, will become one of the associate editors of this journal. Mr. Bain was formerly an officer of the United States Geological Survey and at another period he was in charge of mines in Colorado.

COPPER quotations are not affected adversely by the February statistics of the Producers Association because, although an increase of 28,000,000 pounds of the metal has been made during the month to the stock on hand, it is known that some large sales were consummated early in March, so that the position is not as bad as the statistics indicate.

IN our issue of February 20, we indicated the probable failure of the bill to create a Bureau of Mines. Unfortunately this expectation has been fulfilled, in the manner anticipated, namely, by abuse of that fiction called 'senatorial courtesy' on the part of Mr. Henry M. Teller, of Colorado, who expressed the irritation created locally by the Forest Service and desired to block the formation of any further bureaus likely to check unrestrained exploitation of natural resources.

BY the decision of the United States Steel Corporation to adopt the Heroult furnace, the refining of steel by electric smelting has been advanced to a position of industrial importance in America. The adoption of this furnace is an event encouraging to those who have been, for several years, experimenting with the electric smelting of the magnetite found in Shasta county, California. It will be a matter of moment to parts of the West, where water-power is readily available, when electricity, in lieu of coke, can be used in the reduction of iron ores.

OUR London contemporary, *The Mining Journal*, publishes a leader devoted to the relation of the Geological Survey of Great Britain to its mining industry, proving, in an excellent article, that the British Survey is devoted too much to the scientific, and too little to the economic, aspects of geology. Of this there can be no doubt, and we hope that the ventilation of the subject may lead to a recognition of the importance of a relation so admirably illustrated by the publications of the Geological Surveys of Canada, Australia, and the United States.

AN APPEAL for retention of the duty on lead was made in the House of Representatives by Mr. Burton L. French, in which he declared that "probably only two lead-producing mines in Idaho could pay operating expenses were the duty re-

moved," while the present wage-scale remained unaltered. In other words, the industry would collapse except when aided by the silver obtained as a by-product in the refining of the lead. As the precious-metal content is variable, this would render lead-mining precarious at all times in Idaho, in case the American market should be exposed to invasion from abroad.

ANOTHER organization of mining engineers has been formed. The latest expression of professional solidarity is the Mexican Mining and Metallurgical Institute, the first general meeting being announced for July at the City of Mexico. Mr. Bernard MacDonald is the leading spirit and he is supported by a number of representative men. The question of qualifications for membership is under discussion, with a suggestion on the one hand to copy the admission requirement of the American Institute and, on the other, to restrict membership to technical men. We wish this enterprise every success.

FRESH IMPETUS has been given in England to the search for radium owing to a recent lecture on its healing wonders by Sir Frederick Treves at the London Hospital. The stir it has occasioned in Cornwall has stimulated mining in a serious way. A similar spurt, some years ago, led to interest being taken in the pitchblende deposits in the St. Austell and St. Agnes districts, without, however, adding materially to the world's scant stock of this rare element. It remains to be seen whether or not the new movement is to result more favorably. At all events the experiment is creditable to the mining enterprise of the Duchy, and it will be followed with keen interest. Trewith, near St. Ives, is the mine presently commanding most attention, the capital (£40,000) to open which has been found privately by people who are known in connection with large financial firms, so that there will be no failure for want either of money or of intelligent direction in the spending of it. The concern is known as the British Radium Corporation Ltd. It is said that the total of this much coveted commodity hitherto won from nature scarcely amounts to ounces; this and the statement that pitchblende, the containing mineral, yields radium only in the same feeble proportion as there is gold in sea-water is certainly not economically encouraging though its least value is put at £20 per milligram. By existing arrangement all radium that may be obtained by this corporation from the pitchblende of Cornwall is to be retained in Britain. It will be sold to the Radium Institute of London, which has been called into existence on the initiative of the King. Among the results anticipated from these discoveries in Cornwall is a new development in photography. So strong is the luminosity of radio-active emanation that a piece of ore placed in front of an ordinary photographic plate in a dark room was found, after a short time, to have photographed itself. This effect, thus accidentally discovered, gives promise of a new branch of photography.

Calumet & Hecla Dominant.

The calumet has been filled and smoked. Peace has been declared by the big chiefs at the Boston pow-wow, and the quiet atmosphere that commonly prevails at 12 Ashburton Place will remain as of old. It was the heaviest storm that has assailed the Calumet & Hecla for decades, and the public refused to accept the celebration of peace with Mr. Bigelow as increasing the immediate value of the stocks of the great copper company, in spite of the longer life it has secured by the compromise just made. It was only three years ago that the Calumet & Hecla was credited with carrying liquid assets of seven million dollars; this year, when it adds 17,375 acres of copper-bearing lands with other notable assets at a cost of \$8,500,000, it issues notes for \$5,000,000. Truly, money is not as easy as it was. The copper producers may perhaps be selling their output as fast as it is mined, but the conservatives in Boston seem to consider the chances of dividends impaired by the assumption of such obligations in the form of a floating debt. Calumet & Hecla shares fell 35 points as a result of the transaction, and the so-called Bigelow stocks also suffered decline. The stock market concerns itself with prospects for immediate income. The expectations aroused by the long look ahead are reflected in the average price of a stable stock, but within a certain range of fluctuation the opinion of the market on the realizable profits as influenced by the current operations of a company are registered, as in this instance, by weaker quotations.

Yet no one can doubt the ultimate benefit to accrue from the absorption of the Bigelow properties. Mr. Alexander Agassiz is quoted as having testified that eleven years of production at the present rate would exhaust the orebody within the boundaries of the Calumet & Hecla lands. The statement seems incredible. We had reason to place the time-limit at 30 years. Even that is a brief period for a mine, when the selling price of its stock causes it to represent a capital of sixty-one million dollars. The actual capital-account of this corporation we understand to be only \$1,250,000, all expansion and betterment since the mine began to pay having been met out of income and charged to operating expense. This is well enough for the original shareholders whose investment represented \$12.50 per share, which shares have since yielded in dividends the splendid return of nearly \$1000 each. To the purchaser of stock today at \$610 the new shareholder participates in an enterprise that must theoretically, and actually so far as he is concerned, pay back a principal of \$61,000,000, with profits.

The Calumet & Hecla has always been characterized by the extreme of conservative finance. It proposed to "attend to its own knitting;" the allurements of expansion were long in making an impression, and splendid opportunities were allowed to pass. In 1905 it secured an amended charter making it a securities and holding company as well as a mining corporation. As such it held 22,671 shares of stock in the Osceola Consolidated Mining Company, of which Mr. Albert S. Bigelow was president. The

right to vote this stock was contested by Mr. Bigelow on the ground of violation of the Sherman anti-trust act, a prior attempt to secure State legislation precluding one mining company from owning shares in another having failed. An injunction was issued, temporarily restraining the Calumet & Hecla from voting the stock, but the decision of Judge Knappen, when handed down, proved adverse to the contention of Mr. Bigelow. An appeal to the full bench resulted in sustaining the previous verdict. It was plain that the future of the Calumet & Hecla depended upon freedom to enlarge its holdings. This fact Mr. Bigelow understood perfectly. A threat of appeal to the United States Supreme Court was a good weapon with which to compel compromise. The original terms were deemed ridiculous; from what we can learn they were not far in excess of what Col. T. L. Livermore and Mr. Quincy A. Shaw, Jr., conceded in the end as being better than litigation and the possible loss of opportunity to expand. It was a wise concession. The Calumet & Hecla management has never been conspicuous for the application of the best practice in mining, but it has been successful. Measured by results it is open to no criticism that may not be dismissed with a smile. The Bigelow properties have achieved no equivalent record. At the Tamarack the cost of producing fine copper has varied from 11 to 13 cents, while its neighbor can go merrily on and make a little money at 9-cent copper on a pinch. It has done it in days gone-by. The fluctuation in the price of Osceola stocks, as the pendulum swung during the long controversy, reflected plainly the preference of the public for the management of the Calumet & Hecla. But Mr. Bigelow's name has been associated with successes, and eminent ones at that. It took a giant to whip the biggest mining company in the world into compromise. Even the Amalgamated could neither whip nor buy it. The seductive bid of \$1000 per share produced no wavering. The Calumet & Hecla has stood alone, and has made its own policy; moreover it has succeeded regularly in realizing a larger average price per annum for its copper than its rivals.

By the adjustment now reached, Mr. Bigelow retires and will cease to be a factor in the mining affairs of Michigan. The properties absorbed are the Osceola, Tamarack, Ahmeek, Laurium, Seneca, and one-third of Isle Royale. The latter mine must not be confounded with the island of that name in Lake Superior. There has been copper mining on Isle Royale also, or a pretense at it, as some individuals in the East recall to their sorrow. There were some particularly innocent persons disappointed in a venture on that somewhat desolate and fog-bound island; some of them were literary gentlemen who could ill afford the cost of the experience. The Keweenaw syncline, with its copper-bearing conglomerates, reappears from beneath Lake Superior on Isle Royale, and the deposits may prove better than the early attempts at exploiting them would indicate. At any rate, rumor attributes to the Steel Trust the intention of entering the world of copper mining as a result of its acquisition of the holdings of the Isle Royale Land Corporation, Ltd., which comprise

83,720 acres on that island. But the Calumet & Hecla will not soon confront a rival in the Steel Corporation, even if the island mines prove favorable. As a result of the consolidation now effected the Calumet & Hecla will control at least 60 per cent of the output of Lake Copper, being nearly 12 per cent of the total copper yielded by American mines.

The Pearce Process.

Among the interesting papers recently published by the American Institute is a description of the Pearce process formerly in use at the Argo smelter, near Denver. This is contributed by Mr. Harold V. Pearce, the eldest son of Mr. Richard Pearce, the inventor of the process and the former manager of the works. It seems almost necessary to apologize for this explanation, for Mr. Pearce is so well known, honorably, almost affectionately, to most of our readers. He directed the operations of the Boston & Colorado works, as the Argo smelter was called, from 1878 until his retirement a few years ago. Visitors were shown the interesting features of an establishment that included examples of the turret roasting-furnace invented by the manager, the large reverberatory copper furnaces developed originally from Welsh practice, the Ziervogel process, in which silver sulphate is leached with water, the precipitation of the silver on copper, and of the copper on iron; but there was always one link in the process of reduction that was kept secret: What happened to the residues after the leaching of the silver from the roasted ore? Many were the guesses made by Egleston, Roberts-Austen, and other professors of metallurgy who visited the establishment. And some of them guessed shrewdly, for Mr. Harold Pearce explains that the gold was concentrated in copper bottoms, which were granulated and smelted with iron pyrite in a reverberatory. A further concentration was thus obtained, the solubility of gold being greater in metallic copper than in copper matte. These granulations were made until an alloy containing 10 to 20 per cent gold was attained. This was sent to the refinery, where the same process of concentration was advanced a further stage by repeated melting in crucibles, yielding a gold bullion, 920 fine, which was ready for the Mint. As Mr. J. W. Richards, of the *Electrochemical and Metallurgical Industry*, says, "the process depended on the 'distribution co-efficient' of the relative solubilities of gold in metallic copper and copper-iron sulphide and the ability to successively increase the mass of copper-iron sulphide by the addition of iron bisulphide." It is worthy of such dignified characterization; the Pearce process of gold refining as an incident to the smelting of copper ore was responsible for an output of 1,532,905 ounces of gold during a period of 30 years; for the process was applied at the little smelter at Black Hawk that was the predecessor (in 1873) of the Argo plant. When the refinery was burned in 1906, the management decided that it was inadvisable to re-build it, and thereupon the Pearce process ceased to be employed, its place being taken by the modern method of electrolytic refining.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

O. B. PERRY is here.

T. H. PROSKE is at Denver, on his return from London.

F. PERCY ROLFE has returned to London from Colombia.

RALPH ARNOLD, now at Washington, will shortly move to Los Angeles.

R. GILMAN BROWN, now in London, will proceed to Manchuria shortly.

GUY A. R. LEWINGTON is on his way back to Dawson, Yukon Territory.

D'ARCY WEATHERBE has been seriously ill with pneumonia at Rio Tinto, Spain.

A. C. BEATTY was here, on a visit to the Stone Canyon coal mine, near Monterey.

JOHN B. FARISH is examining the Argonaut mine, in Amador county, California.

EDWIN A. AUSTIN has returned from Colombia, and will soon go to Dawson, Yukon.

D. C. BARD is at Placerville, Idaho, in the interest of the Globe Mines Exploration Company.

J. H. MACKENZIE has returned to Goldfield, where he will remain for two or three months longer.

GEORGE W. BORROWE is at Cordoba, Vera Cruz, Mexico, where he expects to remain about one year.

W. E. SIMPSON has been appointed manager of the San Francisco del Oro mine, in Chihuahua, Mexico.

E. H. NUTTER, lately superintendent of the Liberty Bell mine, in Colorado, is now at San Jose, California.

ALEXANDER F. REID, formerly metallurgist to the Montana Mining Co., has gone from Victoria, B. C., to London.

J. E. WOODMAN, of Dalhousie University, Halifax, has been appointed professor of geology in the University of New York.

EDGAR H. TAYLOR, lately manager of the Boulder Perseverance, is now manager of the Lancefield mine, in Western Australia.

S. WALTER SWING has resigned as general superintendent for the Cinco Estrellas Mining Co. and is at present on a trip to the East.

ROBERT BELL, former State mine inspector for Idaho, will become associated with John A. Kirby in the mining business at Salt Lake City.

F. H. MORLEY has returned to Denver from Jalisco and Oaxaca, Mexico, where he has been engaged in professional work for the Chicago Exploration Company.

CORTLANDT E. PALMER has resigned as director and consulting engineer of the Esperanza company, to take effect April 1, after six years of continuous service.

THE PACIFIC COAST division of the Mining and Metallurgical Society of America will meet at the Key Route Inn, Oakland, at 7 p. m. on the evening of March 13.

OWEN RICE, manager of the Dives-Pelican and Seventy-Three mines at Georgetown, Colorado, has resigned, to accept a position with the Lodi Mines Co., of Bob, Nevada.

HENRY M. ADKINSON, manager for the Gold Pioneer Mining Co., at Telluride, has also assumed the management of the Morning Star Mining Co.'s property near Ophir, Colorado.

Obituary.

EDWIN REYNOLDS, one of the great mechanical engineers of the country, and for 30 years practical head of the Edward P. Allis Co., now the Allis-Chalmers Co., died at Milwaukee on February 19, at the age of 75 years.

General Mining News.

ALASKA.

(Special Correspondence).—The Western Federation of Miners has issued an official circular calling attention to the fact that there is a strike on in the Nome district. This is in response to the wholesale hiring of Russian Cossacks, Greeks, and Laplanders by the Pioneer Co., which is working more men than all the other operators combined. As a consequence labor conditions are still unsettled, for laborers are scarce and the winter's output of placer gold will be sensibly less than last season. One operator is offering \$4 per day and board to competent non-union men.—At Fairbanks, on the other hand, there is abundance of labor, and a boom in quartz mining, with \$5 per 8-hr. day as the established scale of wages.—The recent gold quartz strike reported on the Koyukuk river turns out to be on the Koyuk, and is 150 miles up the river on two small tributaries of that stream, just across the divide from where the Parantulik river empties into the Fish river. Rich samples of the ore have been brought out by prospectors who have arrived in Nome.—A new find of placer diggings is reported from Gold Hill, a new camp near Hot Springs.—On Sullivan creek two laymen are blocking out a huge pay-streak that is said to average an ounce of fine gold per ton.—Coal in Nome this winter costs \$20 per ton inside the city limits, and \$5 to \$7.50 additional per ton on the adjacent creeks; flour \$5.50 per 100 lb.; eggs \$1 per doz.; potatoes \$4 per case; apples \$2.50 per case; beans 8c. per lb., and bacon 25 to 35c. per lb.—A party of prospectors left Fairbanks on December 30 for the Tatalina district, and two days after a stampede was started for the scene of a supposed strike on Tatalina river, which is a tributary of the Tolovana. The stampede, about forty in number, have located all of Washington creek and about six or eight miles of the Tatalina, above the mouth of Washington creek. This report was confirmed by telegraph from the Government Station at the mouth of Tolovana river, 117 miles above Fort Gibbon.—Twelve new camps have been started since Christmas the lessees of which are members of the W. F. of M. at Nome. The local miners are said to be financing these operators and providing them with union labor to prevent 'open-shop' methods of the anti-union operators.—The Westinghouse Electric Co. is reported to have purchased the Chicago creek coal mines near Candle, for generating electric power to transmit at 60,000 volts to Nome. This power is to be used in operating sea-pumps for ground-sluicing a vast area of graveled tundra into Bering Sea. The project is one of the most gigantic mining enterprises ever attempted. It will be capitalized at \$60,000,000, and will include the purchase and operation of 18,000 acres of placer-ground around Nome, besides the Nome Slinnook Mining Co.'s ground, covered by the Nome Townsite patent on which the city of Nome is built.

Nome, January 15.

ARIZONA.

COCHISE COUNTY.

The Fink silver property on Silver creek has been bonded by the owners, Albert Fink and Shaw Bros., to S. S. Suplee and J. P. Ewart, of Douglas. The sale price agreed upon is \$25,000, under terms covering a period of 18 months. The Fink group consists of three full claims and a fraction, situated in the foothill belt about three miles east of Paradise. The shaft, long since abandoned, will be timbered and made ready for production.—A gasoline hoist has been installed on the property of the Bisbee Extension Co., and a 2-drill compressor is being put in. A pipeline has been completed for the purpose of conveying water for the underground operations and is now ready for the water to be turned on. Drifts are in progress on the 400-ft. level, to reach an orebody exposed on a level above.—The recent strike of a large body of ore on the 700-ft. level of the Tombstone Copper Mining Co.'s property is considered very encouraging, as this is 200 ft. below the water-level of the

region. The 40-stamp mill is working regularly, and despite the great volume of water with which the company had to contend before the big pumps were installed, there is now no difficulty in handling the water, about 6,000,000 gal. per day being taken out of the shaft.

MOHAVE COUNTY.

The Tom Reed Gold Co. is bringing in much lumber for the development of its mine. The main shaft is being sunk rapidly, and will be hastened when the compressor is in place. This is now on the ground, and will be able to run 18 drills.—The Golconda mine is shipping zinc ore to the smelter, and the mine is improving with depth. In the winze from the 100-ft. level there are three feet of clean zinc ore running above 50 per cent.

PIINAL COUNTY.

Plans are under way for the consolidation of the Eureka mines with the Globe Consolidated under the name of the Cordova Copper Co., with a capitalization of \$3,000,000.

YAVAPAI COUNTY.

The Vulcan Copper Co., operating in the Jerome district, is ready to start two shifts on its property in Deception gulch. Joe Larsen is superintendent.—The Verde Grande Copper Co., near Jerome, has pulled its pumps and ceased all work. The manager states that he does not know when work will be resumed.—The Arizona Power Co., installing a plant on Fossil creek to develop electricity by water-power, reports that the power-house is completed and one of the three big generators is now in place. The towers are set and the transmission lines have been strung to Jerome. The Jerome sub-station will be ready for business by the latter part of April. Present contracts with the company call for the delivery of 1500 horse-power.

CALIFORNIA.

AMADOR COUNTY.

The Argonaut Mining Co. has been reorganized. The holding company of the Argonaut, the Argonaut Consolidated, was represented by A. H. Carlyle, Jesse W. Lilienthal, E. A. Stent, J. H. Tam, and John Raggio, of Stockton. A board of directors for the year was elected, including J. W. Lilienthal, E. A. Stent, John Raggio, R. S. Rainsford, and B. F. Taylor. J. W. Lilienthal was elected president. B. F. Taylor vice-president, E. V. Zumbiel secretary, and R. S. Rainsford superintendent. The development of the property will proceed steadily.—The shaft of the old Central Eureka mine, has been repaired to within 400 ft. from the bottom of the mine. The company intends, so it is reported, to develop to greater depth. Some assessments may be necessary to get the mine upon a working basis.

INYO COUNTY.

J. W. Rossi is developing his prospect in the Sierra foothills about three miles south of Keeler. Assays of surface rock give returns up to \$12 per ton. The vein was discovered by trenching, cutting the ore at three or four feet underground.

KERN COUNTY.

(Special Correspondence).—The Knickerbocker Mining & Extraction Co. has taken over the Edith and four other claims, and is arranging to work the holdings on a systematic scale. Machinery has been purchased and a force of men will be put to work at once. The main vein is 3 ft. wide and runs about \$25 per ton in gold. Joseph McNight is president and manager.—A gold-bearing vein with tungsten ore is said to have been discovered by J. D. Feris in his claim in Caliente canyon. A new 10-stamp mill has just been completed at the Zenda mine, under bond to Johnson & McCarty. A tramline has also been completed from the mine to the mill and arrangements are being perfected for operating on a large scale.—Johnson & McCarty have taken a bond on the Pearl mine and are about to commence active work. A 40-ft. vein carrying fair ore has been opened up and will be treated at the Zenda mill.—At the Amalie mine the shaft is down 500 ft. and about 50 men are on the pay-roll. The low-grade ore is treated by a Huntington mill and the high-grade is shipped to the

Selby smelter.—The Gold Peak mine is practically idle owing to the large volume of water encountered, and other unsatisfactory conditions.—The shaft at the Atlas is down 150 ft. The vein runs from 3 to 6 ft. wide and assays about \$20 per ton.—It is rumored that a New York corporation is considering the installation of an electric smelter at Paris to treat ore from the numerous properties in the district.

Bakersfield, March 6.

MONO COUNTY.

A new copper and gold camp, situated near Gardnerville, may come into prominence. Four properties are producing ore in the new camp, some of which is reported to have run as high as \$36 a ton. The name of Crystal City has been adopted for the camp. The country has been staked out for three miles.

NEVADA COUNTY.

The orebody on the 1400-ft. level of the Pennsylvania mine continues to show up well. Considerable good ore has been recently taken out. Over 100 men are employed and the mill is running steadily. Bennet Opie is superin-

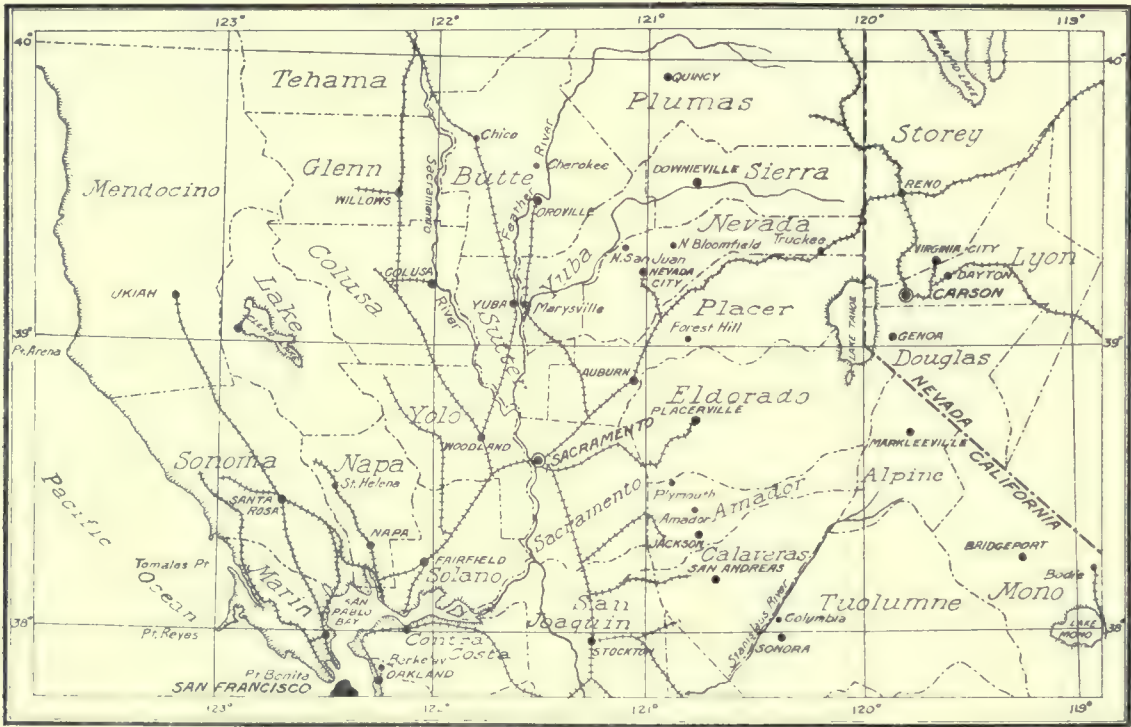

and has disclosed ore more than 9 ft. wide, most of which is of good milling grade. The mine is situated at Maybert, on the South Fork of the Yuba river.

SIERRA COUNTY.

The management of the Snowdon Hill mine is making a large gravel dump and putting in a flume in anticipation of soon striking the channel. The adit is now in nearly 250 ft., and when another hundred feet is run, probably in a little over a month, a raise will be put up into the gravel.—Several men have been laid off at the Papoose mine. There is abundant rock in sight that will mill \$4 and \$5 per ton, but as the sulphides are of the greatest value, and as yet there are no concentrators in the mill, it was thought best to put in concentrators at once. Some of the machinery is now at the mine and the rest in Sierra City. The remaining parts will be hauled to the mine and put in place this week.

TRINITY COUNTY.

C. E. Goodyear, general manager of the Union Hill mine, reports satisfactory conditions at the mine and with the ditches. These are now running full of water, and he has

Map of Central California.

tendent.—A rich pocket of ore has been found in the Greek vein at Union Hill. The mine is showing up splendidly and several men have been recently added to the payroll. Clifford Graham is manager.—At the Empire the 40-stamp mill is running at full capacity and extensive work is going forward in the upper and lower levels. It is understood that the monthly production is considerably over \$50,000. As soon as the new plunger pumps have been installed sinking will be commenced.—Several rumors are afloat to the effect that work will be resumed this summer at the Allison Ranch mine. This famous property has lain idle for several years, although highly regarded by local mining men.—The mill at the Sultana is working steadily and fair-grade ore is being treated. A large force of men is employed and considerable development work is being done.—The adit at the Belle Union is approaching the vein. Some promising ore has been discovered and a test will be made at the Southern mill, which is being placed in shape for active work.—At the Mountain View developments are being actively pushed. Stopping will soon commence. It is expected to have the new mill erected during the coming spring. E. B. Miller is superintendent.—The Hamilton brothers are sinking a shaft in the South Lindsay mine at a point 350 ft. along an adit they have driven to cut the vein. This shaft is at present 16 ft. deep,

three monitors playing on a gravel bank over 600 ft. in width.—It is reported that a good strike of sylvanite has been made at the Yellow Jacket mine in the East Fork mining district.

TUOLUMNE COUNTY.

Operations were resumed last week at the Driesam mine. The temporary cessation of work was caused by the caving of a drift on the 200-ft. level, the mushy falling ground running into and partly filling the shaft.—High-grade ore has been found on the 2200-ft. level in the Eagle-Shawmut mine. The ore is of such unusual richness as to have caused the management to decide to continue sinking the shaft.—The Bonanza mine, situated within the limits of the city of Sonora, is to be worked again. Preparations for re-opening the mine are now under way, and in a short time active work will be commenced.—The Nave-Musso mine, near Jacksonville, have been bonded to A. W. Copp, and active work will be commenced soon. The ore assays \$14 gold per ton and carries 2% sulphides that assay \$492 per ton.—The shaft at the Jubilee mine is being re timbered, preparatory to resuming active work.—It is reported that a valuable strike was recently made in the Arbona mine at Tuttletown.—There is an unusual stillness at the property of the United Mines Corporation, due to the company's failure to pay its employees on March 1,

the majority of whom are owed three months' wages. As a result of the company's failure to meet its obligations, liens and attachments aggregating several thousand dollars have been filed against the property. It is understood that a dispute between some of the stockholders led to the present state of affairs. It seems to be the general belief, however, that the property will not remain idle long.

COLORADO.

BOULDER COUNTY.

The Ward Gold Cyanide Milling Co. has broken ground for the foundation of a mill which will treat custom ore as well as the ore from the company's own property. The mill will be situated on Indiana creek within a short distance of the railroad running from Boulder to Ward.

TELLER COUNTY.

The output from the Cripple Creek district for the month of February is valued at \$1,145,204, or about \$200,000 less than January. The tonnage for the month was 52,716, being 9000 tons short of January. This is explained by the fact that the Wild Horse and Copper mine cyanide mills were closed down during the entire month and that February had three days fewer than the previous month.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence).—Shaft-sinking in the Caledonia mine at Wardner has been stopped for a few days on account of the heavy flow of water. An electric pump with a capacity of 500 gal. has been ordered and as soon as this is installed work will be resumed. In the meantime the drift is being advanced, and from 20 to 50 sacks of ore daily prepared for shipment.—Upward of 1000 sacks of high-grade ore have been sorted and are ready for shipment from the St. Joe Quartz Mining Co.'s property. It is expected that regular shipments will be made throughout the summer.—Operations have ceased at the Galena property at Burke, and the workings of the mine have been boarded up. A small fortune has been spent in development, and recently a shaft was sunk to the 600-ft. level. A considerable amount of drifting has been done, but the showing is said to have been disappointing.—Work on the Hidden Treasure mine in the Lane district has been stopped pending the installation of pumping and other machinery. The whole bottom of the shaft is in mineralized matter showing a stringer of 14 in. of good galena.—The car of ore which was recently shipped to the smelter at Tacoma from the Mineral Point property in the Osborne district has been declared to contain 174 oz. silver, 3.7% copper, 37% iron, and 21.9% silica. It is expected that shipments will be made at regular intervals.—Ben E. Hervey, of Spokane, who took an option some time ago on the property of the Four Ledge Mining Co., has just made the final payment of \$10,000. The property has been well developed and an excellent showing made in all the workings. A contract for 100 ft. of work has just been let to Hugh Mabin and others.—The first cross-cut from the foot-wall to the hanging wall in the drift of the Amazon-Dixie mine in the Lookout district has opened up about 18 ft. of good-grade milling ore, and the hanging wall is not yet in sight. The depth is about 200 ft., and the ore assays from 6 to 10% lead. Arrangements are being made by the company for the use of the Leslie compressor during the installation of their own plant.

Wallace, March 4.

ROOTENAI COUNTY.

The Copper Prince Mining Co., in the St. Joe district, intends to erect a hotel to cost about \$5000, the upper portion of which will be for the accommodation of miners, while a regular hotel business will be conducted on the lower story. In addition to this the company will install a 10-drill compressor and a flume over a mile long. The company owns 12 claims and has a good showing of ore.

KANSAS.

CHEROKEE COUNTY.

The most important recent work in the Galena camp is the draining of Short Creek bottoms, which was once one

of the most famous of Galena's producing tracts. Unusual interest is being taken in the work because it is known to contain rich ore, and old-time miners are hastening to secure leases upon the land. The pumps have now been started and the water is slowly receding. It is thought that it will be only a short time before work can be resumed in the upper levels.

MICHIGAN.

Superior & Boston is now shipping an average of 70 tons of ore daily from the Great Eastern shaft. John H. Rice will be in Globe this week and it is possible an announcement will be made as to the disposition of the Collins-Doyle tract which is optioned to Superior & Boston.—It is possible that Calumet & Hecla will resume exploratory work on the Delaware property next spring. The company owns an immense tract upon which only a little exploration work has been done. It is understood that two diamond-drills will be utilized.—The drift on the thirteenth level of Keweenaw is being driven at a rate that will disclose the west fissure-vein within a few days. This vein carries an encouraging amount of copper where tapped on the level above. The company is milling about 110 tons of 'rock' daily.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—The Trinity mill at Porto Rico has started operations after a period of several idle months, caused by low ore-prices and the litigation in which this company has been involved. This plant is almost new and has a capacity of 500 tons. It works upon sheet ground similar to other properties in the vicinity.—Plans are under way for the installation of centrifugal pumps on the Lone Elm Hollow tract, northwest of Joplin, to drain this old camp which was once the centre of mining in Joplin.—Activities are noted in the Zincite camp, where some large pumps have been installed by Gundling & Maitland. The water has already been drained from the shallow workings, so that a number of old leases have re-opened and are working down to the 80-ft. level.—The Victoria mine in this camp is again producing after battling for some time with heavy water which became almost unmanageable when new prospecting was undertaken. It is a good producer and has again been able to place its name on the weekly production list.—Two large calamine producers have attracted the attention of the camp. On the Hall and south of Duenweg over \$40,000 worth of ore has been taken from less than one acre of ground in the past year. The ore was first taken from the 90-ft. level, but ore was also found in the bottom of the mine, and sinking was continued below the 100-ft. level. Prospecting reveals a large acreage underlain with the splendid deposits, whose extent is unknown, but is sufficient to last many years. The ore is the best grade of its kind and brings the top market price.

Joplin, March 5.

MONTANA.

FERGUS COUNTY.

Twenty-eight tons of ore from the Cumberland mine at Maiden, of which Peter Rosse is superintendent and part owner, netted \$7159 at the Panhandle smelter, where it is reported to be the richest ore yet handled at the plant. The ore was hauled 20 miles by team and then shipped by rail to Idaho. The Cumberland was discovered by Rosse, who four years ago obtained R. M. Calkins and Oscar Stephens as partners. It was being developed when the sudden death of Stephens put a stop to the work, and it has only been pursued at intervals since.

NEVADA.

ESMERALDA COUNTY.

The Goldfield Miners' Union, at its recently held semi-annual election, selected Owen Barnes as president; David Schultz, vice-president; J. J. Mangan, secretary and treasurer, and Chris. Dutler, recording secretary. J. J. McMahon, William Agran, and John Donald were elected to the committee on Finance. A. L. Anderson, Joseph Hamil-

ton, and Richard Egan were elected as trustees for the next six months, while Angus McMillan was chosen as conductor, and Emil Tennant as warden. Four hundred and fifty-one ballots were cast.—The annual report of the Pittsburg-Silver Peak Gold Mining Co. at Blair is being received by stockholders and announces that during the year 1908, 105,670 tons of ore were treated in the company's mill. The bullion receipts amounted to \$848,713, while the operating expenses were \$499,789, making the net earnings \$348,932. The report states that the plant has given complete satisfaction and that all imperfections have been remedied. The mill has been operating on an average 93.1 stamps during the month of January 1909, the balance being held in reserve for emergency use.—The ore tonnage treated and shipped from the mines and leases of Goldfield district during the past week, according to the *Tribune*, amounted to 5975 tons, valued at \$226,700. A total of 685 tons of gold ore was received by the Nevada-Goldfield Reduction Works, the average grade of which was about \$40. Included in the total was a shipment of 405 tons from the Combination Fraction. There also was one carload of 50 tons from Pioneer that ran \$4500. The Consolidated—at both mills—treated approximately 600 tons of ore each day that probably averaged about \$40. This gives a treatment of about 4200 tons to the week, representing a value in the neighborhood of \$168,000. The Florence has thirty stamps running and is turning out about 840 tons per week of ore that will mill, as a rule, about \$20 per ton. The Western Ore Purchasing Co. sent out about 200 tons by the railroads.

HUMBOLDT COUNTY.

(Special Correspondence).—The Seven Troughs district has now been proved for a distance of 12 miles along the mineral belt. Development work is active throughout the whole length, and some bullion is being produced.—The Seven Troughs Mining Co. received a \$13,000 draft last week for bullion sent to Carson City, obtained from a 10 days test-run of ore through the Kindergarten Co.'s mill. This mill is now treating a 100-ton lot of Wihuja lease ore, from the Seven Troughs Coalition estate. Wihuja ore averages \$80 per ton, aside from the high-grade, which assays \$20 per pound. The Florence lease, on the Seven Troughs estate, is fast developing into the greatest mine in this rich district. They have taken out over 100 tons of ore during the progress of development work, averaging \$80 per ton. This ore comes from a vein about 5 ft. wide, cut by stringers of high grade, and shows every indication of great persistence. The deepest workings on the company's estate are now 750 ft. down, and are still in ore, all production of which is sent to the Kindergarten mill. Other smaller properties, but of hardly less importance, are also doing famously.—The Big Dipper, adjacent to the Seven Troughs, shows free gold in a 2-ft. vein which assays over \$50 near the surface.—One hundred thousand shares of Seven Troughs Coalition stock have been sold recently at par, giving some idea of the local esteem in which the property is held.—The Mazuma Hills Co. received \$1500 recently from a clean-up in the company's mill of 125 tons of ore. The mill is now treating ore from the Reagan lease, a rich producer on the same estate.—The mill on the Badger Hill group of claims averages a clean-up of over \$1000 per week.—Three mills are in successful operation, and the fourth is expected to be ready early in April; further, plans have been made for the construction of two more. Altogether the Seven Troughs and Vernon districts have every reason to congratulate themselves.

Vernon, March 6.

LANDER COUNTY.

The Austin Manhattan Consolidated Mining Co. of Austin has almost completed its 6000-ft. drainage adit connecting the mill with the bottom of the Frost shaft. A cross-cut 2800 ft. long from this adit has been cleared out, and the Isabella shaft opened to the 600-ft. level preparatory to mining the ore of milling grade.—The Hardy property is being developed by a drift on the vein, which is 5 ft. wide at the 50-ft. level, and assays \$20 per ton, chiefly in gold. The present 30-stamp mill will be re-modeled to treat the ores

more efficiently. For power the company expects to use California fuel oil in large units of Diesel engines.

NYE COUNTY.

The Nevada-California Power Co. is to build at once to Round Mountain and Manhattan. The company, under the terms of its agreement should have a full power service installed by May 15. Most of the mines in the district are down to a depth which makes gasoline power costly and, in some cases, impossible. The mills now operating in these camps have been using steam-power, but with wood costing \$8, and often more, per cord, the question of economical power became an acute and pressing one for them.

Four hundred and seventy-five votes were cast at the election held by the Tonopah miners' union. The closest contest was that for president, Frank Darrah being defeated by M. J. Scanlon by eight votes. Other officers elected for the year include J. P. Murphy, vice-president; P. A. Lee and R. H. Ralzell, secretaries; and Dennis Murphy, conductor.—The 40-stamp mill of the Montana Tonopah Co. crushed 757 tons of ore from the company's mine and 233 from the MacNamara, a total of 990 tons, returning an average extraction of 89.4%. A total of 228 ft. of development work has been done, which is in excess of any week's record for some time past. The new refining plant is working well, and produced 21 bars of bullion as the result of the half monthly clean-up.—Preparations are being made to unwater and clean out the old Belmont shaft. A sinking pump and small hoist are on the ground, and a pipe-line to convey air for power is being laid. No trouble is anticipated from water, as the cross-cut on the 1000-ft. level, fully 400 ft. deeper, is absolutely dry. When the cleaning of the shaft has been completed a 6-inch churn drill-hole will be put down to connect with the cross-cut on the 1000-ft. level, requiring about three weeks' time. A raise will then be started from this cross-cut on the 1000-ft. level, and when the bottom of the present 2-compartment shaft is reached, the latter will be enlarged to 3-compartment.—During the past week a change in the superintendency of the Jim Butler has taken place. Alex Johnson, who has been the superintendent of the mine for the past 15 months, has resigned, and S. H. Brady, of the Belmont, has been chosen to fill his place. There is no change to note in the appearance of the various stopes this week, the usual output of 300 tons having been extracted and sent to the mill.—The work being done at the end of the 400-ft. level in the extreme westerly workings of the Tonopah Extension Mining Co. is proving an excellent body of ore, showing a width of over 10 ft., all of which is of good milling quality. Raise No. 3, near the boundary of the Tonopah Mining Co., has been advanced 40 ft. in ore all the way. The vein at this place is in two streaks, aggregating 10 ft. in width, being separated by about two feet of porphyry.—The Pioneer lease has started shipping ore from the 210-ft. level. About ten days ago the ore-shoot was reached, and the interval has been consumed in an effort to prepare the ground for smooth production. A 6-drill compressor is expected next week, together with a 60-hp. engine.—The Mayflower mill was started this week and christened with a bottle of champagne. Considerable trouble was experienced at first in the mill by reason of faulty and unadjusted pumps. By Thursday these difficulties had been overcome, and on that day the plant was running smoothly.

WHITE PINE COUNTY.

E. W. Walter, who for the last two years has been general manager of the Giroux Consolidated Mines Co., has left Ely and will go to Hillside, Arizona, where he becomes manager of the Copper Creek Copper Co.—The Nevada Consolidated and the Cumberland Ely Copper companies, which jointly control the Steptoe smelter, have just put into commission a third reverberatory furnace.—It is reported that the power-plant at the Giroux Consolidated mines will be augmented and that large pumps will be installed in the Alpha shaft. Good ore is opened up in the Alpha, Monster, Bunker Hill, Brooks, Morris, and Old Glory shafts.—Considerable impetus has been given to the mining industry in the Ely district by the reports of the early

construction of the Ely-Goldfield railroad.—The lead and silver mines are commencing to attract attention and it is likely that considerable work on these properties will be pushed during the summer.

NEW MEXICO.

GRANT COUNTY.

The enthusiasts of Sylvanite declare that all their ore exceeding \$15 per ton can be shipped at a profit. The rate for hauling ore to Hachita is \$2.50 per ton. Transport to the Douglas smelter for ore worth less than \$50 per ton is \$1. When ore carries 75% silica or less, the smelting charge is \$2 per ton. If over 75% a premium of 15c. per unit is paid, and most of the Sylvanite ore falls into this class.

The Gold Hill mine continues to develop most satisfactorily, and two shifts of miners are employed in both the east and west adits. The west adit is now in 160 ft. and has to be driven about another 60 ft. to strike the ore-shoot opened in the upper workings.—The directors and management of the Monte Cristo Mining Co. are so much encouraged by the result of the first shipment from the Pearl mine that a second consignment is now being prepared.

SOUTH DAKOTA.

CUSTER COUNTY.

(Special Correspondence).—Two new veins have recently been discovered on the property of the Saginaw Mining Co., one of which, east of the mill, shows gold to the extent of \$6 to \$15 per ton; this vein is about 8 ft. wide, and is being largely drawn upon as supply for the mill. The company's mill treats 50 tons per day, and is well equipped for cyaniding. J. W. Herber is manager.—The Ideal Mining Co., of which A. N. Connor is superintendent, is making slow progress with the erection of its mill on account of the bad weather. Connor announces that a full force will soon be employed in both mine and mill.—The New York and White Spar mica mines, belonging to the Westinghouse Electric Manufacturing Co., situated 6 miles west of Custer, has partly closed down for the present, while they are changing machinery and erecting new houses. Joseph Payne is superintendent at the mine.—The 10-stamp mill at the Ruberta has not yet been started, principally on account of trouble with the Forest Service. The company has been forbidden to take timber from one of the claims in its group to be used at the mine and mill which are situated on another claim of the same group.

Custer, March 5.

UTAH.

BEAVER COUNTY.

The Cactus mines of the Newhouse Mines & Smelters Corporation ceased production on the first of the month. T. R. Drummond states that during the six weeks or so that the mill will be undergoing changes, the work underground will be reduced to that of about 30 men kept on development. It is expected to get under way again about the middle of April, and then treat an average of about 25,000 tons of ore per month.

SALT LAKE COUNTY.

A deal is on foot at Bingham whereby the Butler Liberal, Utah Apex, and the Red Wing properties are to consolidate and be called the Utah Northern. It is said that there are English and Scotch capitalists behind this consolidation.—Stockholders of the Boston Consolidated Copper Co. have been asked to authorize the issue of 50,000 shares at \$11.25 per share. It is said that the new issue is to meet floating debt, due to drawing on copper when the price was much higher than at present. Then there was trouble at the mine when it temporarily became necessary to abandon steam-shovels, and there has also been much delay in getting the mill into commission. All of which accounts for the poor position in which the finances of the company now stand.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence). The last carload of ore

shipped by the New Republic Mining Co. went to the Granby smelter, at Grand Forks, B. C. Its gross value was estimated by the management to be about \$15,000, or \$357 per ton. The company is now employing 54 men and expects to slightly increase the force in another week. The new machinery for the mine is reported to be at the railway depot and will be delivered and installed without delay. It consists of a Fairbanks-Morse 5-drill air-compressor, a 25-hp. electric hoist, a 3-phase dynamo, 3 St. Clair air-hammer drills, and 1 heavy piston-drill. The compressor has a capacity of 355 cu. ft. of force-air per minute at this altitude, and it will be installed close by the hoist and drill-sharpening machine. At the first regular meeting of shareholders there was elected an executive committee consisting of L. W. Anderson, J. L. Harper, and J. E. McFarland.

Republic, March 5.

LEWIS COUNTY.

The little village of Mayfield has been enlivened during the last two months by the staking of numerous claims by prospectors and by the farmers of the region. The main belt of ore is said to run in a southeasterly direction across the Cowlitz river and across Winston and Salmon creeks for a distance of eight miles. It is essentially low-grade and free-milling, but no gold is visible without assaying. William Harper was the man who made the first discoveries, and George Robinson, of Chehalis, has taken them up with considerable activity.

STEVENS COUNTY.

In the adit of the Copper Cliff mine, near Chewelah, ore was discovered unexpectedly 162 ft. from the portal, and several stringers have since been cut. The property will be incorporated, with Chicago and Seattle people holding the controlling interest. The working force will be increased and the adit advanced to the 300-ft. point, where it is expected the main vein will be found.

CANADA.

BRITISH COLUMBIA.

The Consolidated Mining & Milling Co. has obtained from J. P. Swedburg a 30 months bond on the Queen Victoria mine at Beasley, eight miles west of Nelson. The property is equipped with the most modern machinery, and shipments will be made almost immediately to the smelter at Trail. It is a low-grade copper property, carrying much lime, which adapts it for mixing with the Rossland ore as flux.—An official of the Grand Trunk Pacific has been expressing surprise that the region opened by the new railroad is as yet not attracting much attention from prospectors; but he says that in the Babine range, drained by the Peace river, a good many claims have been staked, and there are indications of copper, silver, and gold. Furthermore, the bed of the Peace river shows black sand, and quite sufficient 'colors' to induce further prospecting. Unlike many of the streams of the southern part of the Province, the bars of the Peace river are almost entirely free from boulders, which would greatly favor the possibility of working them with dredges.—L. R. Broadbent, of the Dominion Geological Survey, is collecting British Columbia ores for the Alaska-Yukon-Pacific Exposition.

MEXICO.

TEPIC.

The Tepic Gold Mining Co. has been organized in Los Angeles, with a capital of \$300,000, to take over and work the Certuchena y Anexas gold mines. S. W. Garretson is president of the company, C. M. Shannon vice president, and J. W. Roberts secretary. The mines were purchased a few months ago from Loneragan & Stanhope, an English firm of Tepic, for \$50,000, the deal being made by Marshall P. Wright, of Los Angeles. There is a small reduction plant at the mines. The plans of the new owners call for modern reduction machinery, and the installation of a hydro-electric plant about five miles from the property. The construction of the Southern Pacific extension through Tepic will place transportation within five miles of the Certuchena mines.

Special Correspondence.

DENVER, COLORADO.

New Processes—Dredging.—Tungsten Mining.

New metallurgical methods of treating ores are receiving much attention at present in Colorado. The management of the Portland Mining Co. at Cripple Creek believes that it has found a method of successfully treating the raw ores of that district. According to the annual report, their metallurgists made thorough tests of the Tippet-Crowe and Clancy processes in their experimental plants and made numerous experiments with a process that will be known as the Portland process. The company believes that this process will save 76 cents per ton for roasting and also \$1 per ton in freight now paid for transporting the ore to Colorado Springs. Exhaustive tests have been made at Black Hawk, in Gilpin county, for the purpose of ascertaining the percentage of extraction in the local mills. The best extraction is said to be about 86% and the average extraction 60%. Nearly all the mills are equipped with amalgamating plates, Gilpin bumpers, and additional concentrators below, of recent patent. The saving in concentrate is nearly constant and the variation in extraction is found to be in the saving on the plates. Various cyanide processes are being tried for the purpose of bettering the extraction. In Clear Creek county, the Western Metals Co. has been organized to build a mill for the treatment of ores by the dry-chlorination process. The Griffith mines at Georgetown and the Stanley Mines Co. at Idaho Springs will be the first to install a plant with this process.

An additional levy of 10% has been made by the Cripple Creek Drainage Tunnel Co. This will amount to \$40,000. About \$150,000 of the original subscription remains unexpended. A total of 6021 ft. had been driven by February 17 and the completion is expected in 11 months. The Reliance dredge at Breckenridge, Summit county, has been steadily operated throughout the winter. This is the first time in this district that a dredge has been operated during the winter months, and the accomplishment of this feat will probably result in the operation of all the dredges next winter. The Colorado Gold Dredging Co. has two dredges in the field and will probably build two new ones of the latest make, as the first season's run has demonstrated that the operation is profitable. Both the Colorado Gold Dredging Co. and the French Gulch Gold Dredging Co. will resume work about March 15. The expense of operating the dredges has been lessened considerably by the entrance of two big power companies, the Central Colorado and the Summit County. It is confidently expected that the big dredges can be successfully operated on the bench deposits above the present placers. The Primos Mining Co. at Eldora, Boulder county, is shipping two cars of tungsten concentrate per day to their chemical works at Primos, Pa. Tungsten concentrate is now worth about \$6 per unit for a 60% product, and an advance to \$8 per unit is expected should the proposed new tariff bill go through. The Primos company is the leader in a movement toward a combination to promote the interests of the tungsten industry.

The shortness of the month, coupled with the severe weather and heavy snow-storms, cut down the ore production for February from all the camps in the State. The precipitation was the heaviest in eight years. In the San Juan district and in some of the more exposed camps of Hinsdale, Chaffee, Gunnison, Eagle, and Summit counties, mining had to be almost entirely abandoned. The enforced idleness at the mines, and the blocked transportation, combined to close the Durango smelter temporarily. The Camp Bird mill at Ouray has also been forced to shut down. At both of these plants the time is being improved in making needed repairs. There is considerable uneasiness in this district over the possibility of disastrous snow-slides as soon as the weather moderates. The production from Cripple Creek fell off 9012 tons, with a decrease in value

of \$217,071. Leadville also suffered severely, but the figures are not yet obtainable.

The Elkton Consolidated Mining & Milling Co. has paid its first bi-monthly dividend for 1909 to stockholders of record on February 13. The dividend was at the rate of one cent regular and one-half cent extra per share, amounting to \$37,500. This makes the total dividends to date \$2,279,466. The Camp Bird mine also paid its regular quarterly dividend of one shilling per share, making a total paid in dividends from this famous property since 1902 of \$5,188,550.

The Denver Y. M. C. A. has instituted a course of lectures

The Central Part of Colorado.

on mining. The work is similar to that carried on by the Y. M. C. A. organization in Pennsylvania some years ago, when special courses of instruction were given in coal mining at the principal mining centres in that State. The lectures remaining to be delivered are: Ore Formation at Leadville, by J. C. Hersey, March 10; Chemical Treatment of Ores, by Philip Argall, March 17; Milling and Concentration, by F. E. Shephard, March 31; Mining Law Applied to Apex and Cross-lodes, G. L. Stevic, April 7; Prospecting, by R. C. Hills, April 21.

The State Land Board met in Denver on March 3 to sell Routt county coal lands. There had been charges of fraud against the old Land Board under the Buchtel administration in connection with the disposal of these same lands,

so the transfer of the land had never taken place. The charges of fraud were not upheld by the present board, and the land was sold in 160-acre tracts at prices ranging from \$10 to \$11.75 per acre. Out of the 5000 acres sold, 3820 acres went to H. H. Eddy and associates. Under the agreement the State reserves the right to collect royalties at 10c. per ton on all coal mined under this land. The land is also valuable for agricultural purposes, as water is available for irrigation.

MAZATLAN, MEXICO.

Transportation Facilities. — Rosario. — El Tajo Mine. — Milling Process. — Bullion Output.

Steamships from Manzanillo to Mazatlan, stop on the way at Las Peñas and San Blas, both ports on the coast of Tepic. Mazatlán, on the Sinaloa coast, has long been one of the most important western seaports of Mexico, and its prestige is now enhanced by connection with the Southern Pacific's west-coast railroad, just finished from Guaymas to Mazatlán. This road is being extended to Guadalajara. But the proposed harbor-improvements at Mazatlán have hardly commenced, the ocean steamships have to anchor in the bay a mile from the shore, and depend upon lighters to convey passengers and freight to and from the shallow landing. Las Peñas is a small town where sloping hills covered with cocoa-nut palms and banana trees come close to the water-front and overlook an open harbor; near by a river empties into the sea and here one gets a view of the trop-

Tajo Mill, Rosario, Sinaloa.

ical verdure of the valley. San Blas is a squalid little seaport, situated close to the mouth of the Santiago river, and from it extends a stage road to the town of Tepic, 40 miles easterly. Mazatlán is a city of 40,000 people, and has some large mercantile houses, but still clings to mule-power for its street cars. The Southern Pacific Co. has its main yards at the head of a small arm of the bay, but has built a spur to the principal wharf. From here wagon roads radiate to different places in the Sierra Madre—to Rosario, Copala, Panuca, Guadalupe de Los Reyes, and Concordia. To Rosario is 55 miles, and the trip is usually made at night, so one cannot see the cloud of fine dust in which he travels.

Rosario is on the river of that name, in the State of Sinaloa, 12 miles from the coast, and only 100 ft. above sea-level. Here is situated the Tajo mine, first opened by Spanish operators 300 years ago. It belongs now to the Bradbury estate of Los Angeles, that family having owned it since 1870. Since February, 1906, the property has been managed by Geo. A. Tweedy. The mine-workings disclose a complicated system of veins in a fractured zone that strikes northeast through an andesite country. The orebodies are irregular, have a dip of 35° to the east, and in some places have a width of 150 ft. The holdings cover 4000 ft. on the strike of this zone. A big tonnage of ore is taken from open-cuts, the main pit from which it is hauled being 100 ft. below the surface. The two principal shafts are 1200 ft. apart, each reaching a depth of 500 ft., though one of these is being sunk below that level. It is a 2-compartment shaft, and is equipped with an electric hoist. There are 80 miles of workings above the 500-ft. level, which is therefore 400 ft. below sea-level. A considerable volume of water has to

be handled, all of which is lifted from one shaft by an electric-driven Gould triplex pump. Much timbering is required, and for this purpose mahogany, ebony, and mesquite are employed. The ore consists of quartz carrying gold, and silver sulphide, but it contains no copper, and particularly no iron, nor other base metals. It is, therefore, capable of yielding a high extraction by simple processes. The old mill, which was in operation prior to the time when the present management took charge, was a pan-amalgamation plant. The new mill, designed and erected under Mr. Tweedy's direction, is situated on the bank of the river, 3800 ft. from the main shaft, and the ore is hauled to the mill by a steam locomotive. The mill has 60 stamps, which crush 3.8 to 4 tons of ore per stamp per 24 hr., through 0.75 mm. punched screens. The crushing is done in a weak cyanide solution. No amalgamating plates are used, nor is there any concentrating equipment or re-grinding machinery. The pulp passes from the batteries to settling tanks, four in number, each 35 ft. diam. by 5 ft. deep. The slime overflows from these tanks, the settled sand is distributed to 14 leaching vats, each 35 ft. diam. by 5 ft. deep; the slime goes to another set of settling tanks, each 35 ft. diam. by 10 ft. deep, thence to 10 tanks, each 24 by 10 ft., having mechanical stirrers and centrifugal pumps. Following this agitation in cyanide solution the slime is passed through an Oliver continuous filter, a second one of which was being installed. The capacity of each press is 70 tons. It is stated that the consumption of cyanide is 1.3 lb. per ton of ore, and that the milling costs amount to \$1.50 per ton. The ore milled averages \$8 per ton, the value-ratio of gold to silver being 2 to 1. The December bullion production was 41,601 oz. silver and 2020 oz. gold, the value of which was \$63,068. It is claimed that the sand and slime tailing average one ounce silver per ton of ore, and but a trace of gold.

SALT LAKE, UTAH.

Copper Production. — Leaching Low-Grade Ore. — Ohio Mine and Mill. — Iron Blossom, Tintic. — Newhouse Mines and Smelter.

The estimated copper output from Utah mines in February is 7,380,000 lb. This is a slight decrease, due to February being a short month and to storms interfering with operations and shipments. At the Utah Copper the output was reduced considerably by the blocking of the railroad line between the mine and the milling plants, but in spite of this interruption the output was approximately half the entire copper tonnage of the State. The transportation question has been a most vexing one for the Utah Copper, and in case anything extraordinary occurs demurrage of plant is sure to follow. D. C. Jackling, manager for the Utah Copper Co., has stated that they have eighty acres of overburden, that carries from $\frac{3}{4}$ to 1% copper, which will give 20,000,000 tons of metal. They have conducted experiments, with the result that it has been proved that a profit can be made from the treatment of this product by leaching. The treatment of this deposit, however, is a question of the future.

Developments in the Ohio Copper properties at Bingham have been the most important in the history of the property. The vein has been opened on the tunnel level, which proves its continuance from the surface, or a distance of 1400 ft. on the dip of the vein. This orebody is 400 by 500 ft. and carries an average of 1.75% copper, and with the by-product of silver and gold, it is one of the big copper properties now being opened in the Bingham district. Colin McIntosh, manager for the company, says that they have ore sufficient to keep their milling plant, with a capacity of 2500 tons daily, in operation for more than 20 years. That is in addition to the tonnage of porphyry ores. The sulphide vein at the Mascotte tunnel level is stronger than it was near the surface, and indications point to continuance below the 1800-ft. level. The tunnel and shaft were completed Sunday, and after the shaft has been straightened up, the ore will be run from the various levels and sent by gravity to the mill at the mouth of the tunnel. The mill will be made ready by April 1, and from that time

forward the Ohio Copper will be one of the greatest producers in Utah.

Iron Blossom is claimed to be the greatest bonanza that Jesse Knight has ever opened up in the Tintic district. He says the vein is traceable more than 4000 ft., and the average high-grade ore recently found shows 40% lead, 113 oz. silver, and \$13 gold per ton. This ore is sent direct to the Tintic smelting plant, which is also controlled by the Knight interests.

Samuel Newhouse has just returned from New York, where he has been promoting the Fink Smelters Company. He says they are now working out plans for the formation of a company that will take over the Newhouse mine in Beaver county, and consolidate it with the Fink smelting concern. This will mean the organization of a large company, and the Fink furnaces will be installed at the Newhouse mines at once. The Newhouse mill is closed while the low prices of copper prevail. The plant is being overhauled to admit of increased capacity. It will be capable of treating 25,000 tons of crude ore per month.

TORONTO, CANADA.

Nipissing. — Dividends by Cobalt Mines. — Canadian Institute Meeting.

At the Nipissing property the Fourth of July shaft is down 165 ft. During February ore valued at \$75,000 was taken from this shaft while sinking. The shaft will be sunk to a depth of 200 ft. before driving is started. The five veins found in the shaft have united, making 8 in. of solid ore carrying 4000 oz. silver per ton. At the 100-ft. level in the Right of Way a good 6-in. vein has been struck. It is probably an off-shoot from the main vein. The company has declared a quarterly dividend of 6%, with a 9% bonus. At the La Rose driving is being done at the 180-ft. level in both directions from the raise, between the 110 and 200-ft. levels, and rich ore is being extracted. A somewhat discouraging report was presented at the general meeting of the Cobalt Lake Co. held at Ottawa Feb. 27. Working expenses for the year were \$142,554 and receipts \$83,547. E. L. Fraleck, the engineer, hopes shortly to cut the McKinley-Darragh vein, and is also endeavoring to strike ore at the north end of the Right of Way. But so far the actual results from extensive development have been disappointing. The Temiskaming & Hudson Bay Co. recently declared a dividend of \$3 per share, or 300%, the shares being \$1 each. This makes total dividends since 1905 of 12,400%. At the Beaver, where for some time endeavors have been made to find the big Temiskaming vein, ore was struck in driving at the 200-ft. level 244 ft. from the main shaft. The vein is smaltite carrying silver. Crown Reserve is looking up in the market, as some rich ore is being worked at a depth of over 150 ft., and is yielding assays of 10,000 oz. per ton. In the Silver Leaf, in endeavoring to pick up a vein which had yielded rich ore, but which some time ago pinched out, a 3-in. vein with silver was cut, the wall-rock also yielding silver. The Otisse mine in the Montreal River district is yielding well. A narrow vein, struck at 43 ft., has developed at the 55-ft. level to a considerable width, and carries silver to the extent of about 3000 oz. per ton, with the wall-rock carrying much silver also. The Elk Lake Discovery in the same district has a rich vein, 1 in. wide, on which a shaft is down 40 ft. On the Big Six a shaft is down 75 ft. on a vein showing silver. A plant has been ordered.

The eleventh annual convention of the Canadian Mining Institute was held at the Windsor Hotel, Montreal, commencing on March 3, with an attendance of several hundred. Willet G. Miller, Provincial Geologist of Ontario, president of the Institute, gave the opening address, reviewing the history of the organization. It was founded in 1898, and its growth and influence had been proportionate to the development of mining industry in Canada, the annual output of the Dominion having increased in the interval from \$38,000,000 to \$87,000,000. The membership of the Institute had meanwhile increased from 65 to 830. He pointed out that the development of Canada's mineral wealth was just beginning. The tendency in the past had been to regard

the maritime provinces and British Columbia as the great mineral areas and the interior provinces as purely agricultural. This was a fallacy, as the formation of pre-Cambrian origin which constituted 2,000,000 of the 3,700,000 square miles of Canadian territory contained great mineral resources. It was in this formation that the Sudbury and Cobalt ores occurred.

The election of officers resulted in the following selections: President, Willet G. Miller, Toronto; vice-presidents, A. E. Barlow, Montreal, and J. Obalski, Quebec; secretary, H. Mortimer Lamb; councillors, W. R. Brock, Ottawa; J. Stevenson Brown, Montreal; Thomas Cantlay, New Glasgow, N. S.; C. J. Call, Stellarton, N. S.; John Donnelly, Kingston, Ont.; E. L. Fraleck, Cobalt; H. E. T. Haultain, Toronto; L. Milton Hersey and J. P. Bonsall, Montreal.

A. C. Lane, State Geologist of Michigan, submitted an illustrated paper on 'The Mine Waters of Michigan', presenting tabulated results of the chemical analyses of waters of the iron mines in explanation of theories as to the mode of deposition. Other papers presented were 'Notes of Mine Examination and Investments Considered from a Commercial Standpoint', by J. C. Haas, of Spokane, Washington; 'Mine Accidents', by E. T. Corkill, Ontario Inspector of Mines; and 'Nitro-Starch Dynamite', by A. Moscovici, Montreal.

MEXICO.

Torreón Smelter. — Smelter Competition. — Monterrey Steel Plant. Zinc Tariff. — Minas Prietas.

According to Ernesto Madero, president of the Torreón Metallurgical Co., the deal that was pending for the sale of that company's interests, including the smelting plant at Torreón and the mines and leases at Cabrillas, Monterrey, Santa Barbara, and Sierra Mojada, to the International Smelting & Refining Co., has been declared off. As the Torreón plant is the only really available one for the International to acquire that could greatly annoy the American Smelting & Refining Co., it would look as though heavy competition against the latter was not yet probable in Mexico. It was rumored that the International was negotiating for Smelter No. 2 of the Monterrey M., S. & R. Co., and also that threats were made that unless Torreón came to terms the International would erect a competing plant at Gomez Palacio, a couple of miles farther north. To anyone familiar with the smelting situation in Mexico, neither of these rumors is worthy of much consideration. The Monterrey company, commonly spoken of as Smelter No. 2, is an independent Mexican concern, and while it has some good mines and leases, and does a good business at its refinery, and usually pays satisfactory dividends, nevertheless the smelting plant is rather a tumble-down affair, consisting of 8 small furnaces, using hand slag-pots, and it is poorly situated. It would not greatly attract a prospective buyer, and to be a worthy competitor in the smelting business in Mexico it would have to be entirely re-built. The Torreón company owns a number of mines and leases, and is thoroughly established after 7 years of operation. Just west of Torreón, in Durango, is the Velardeña plant of the American Smelters' Securities Co., operated by the A. S. & R. Co.; south of the city, near enough to be a strong competitor, is the Aguascalientes plant of the A. S. & R. Co.; east of Torreón, at Saltillo, is the new plant of the Mazapil Copper Co., which does some custom smelting, and at Monterrey are Smelter No. 2 and Smelter No. 3, of the A. S. & R. Co.; while north of Torreón, at Santa Rosalia, is the Encinillas plant, which has finally resumed operations, and by virtue of its recent contract for the San Pedro ores of Naica, and others of Parral, Almoloya, and Sierra Mojada, must be given consideration. Finally at Chihuahua is the new plant of the A. S. & R. Co., now operating three furnaces, to which two more are likely to be added. With a well established plant now operating at Torreón, and others surrounding it on all sides, it does not seem probable that another will be built. Ernesto Madero also states that the A. S. & R. Co. has made no attempt to get the Torreón

plant since the negotiations of three or four years ago.

The Monterrey steel plant is busy getting out its order of 25,000 tons of 85-lb. rails for the Mexican National railroad, and this is a great help to the city commercially, but there is some doubt as to whether the steel company will be able to win a profit on this the largest order it has ever had. The plant itself is apparently satisfactory, but it is stated that the waste and the losses are large. Largely for the protection of this plant was the duty adjusted on iron and steel products, and unless the company can make good there will be no reason for retention of the present tariff.

The decision of the United States courts in declaring zinc carbonates entitled to free entry has added to the good feeling at Monterrey. The petitions of the Missouri and Colorado Legislatures for a tariff on zinc as well as lead ores, however, causes anxiety.

The Creston-Colorado Mining Co., operating in the Minas Prietas district, State of Sonora, is under the management of M. F. Perry. There is an 1100-ft. shaft on the Creston at Minas Prietas, and an 800-ft. shaft on the Colorado mine at La Colorado. These villages are one mile apart, and the mills are at La Colorado. An Otto aerial tramway, 4000 ft. long, carries the ore from the Creston mine, and a shorter tramway from the Colorado, both delivering to the 30-stamp mill, which crushes 7500 to 8000 tons of ore per month. This mill, in addition to the 30 stamps, has 8 Huntington

treated in the leased Butters mill by an all-slime process, consisting of tube-milling, classifying, re-pulverizing, and cyanidation in slime-tanks. The electric precipitation employed in the slime-plant is regarded as satisfactory. Geo. A. Schroter, of New York and Denver, is consulting engineer for this company, and C. E. Cleaveland is superintendent of the cyanide plants. Among the other mill-men are Ed. Powell, P. H. Crawford, and F. E. Steele. Gus. Schoglund is mine superintendent, and R. R. Wheeler master mechanic. The company owns the narrow-gauge railroad that operates between Torres and Minas Prietas, a distance of 15 miles.

JOHANNESBURG, TRANSVAAL.

Metallurgical Progress.—An All-Cyanide Scheme.—Mineral Production. — Electric Power Station.—Accident Rate. — Flood.

A month or two ago, I was able to publish a few notes in these columns with reference to the improvements in metallurgical practice being effected by the Consolidated Gold Fields group. The experiments at the Simmer & Jack and at the Simmer Deep batteries principally affect the operation of pulp-classification. The Eckstein group has also been actively working on experimental lines, and the scheme proposed for introduction on a small working scale at the Bantjes Consolidated (a newly resuscitated mine in

Minas Prietas, Sonora, Mexico.

mills, one Krupp tube-mill, with 14 leaching tanks and hydraulic sizers. The stamp batteries reduce the ore to only $\frac{1}{2}$ -in. size; the Huntingtons follow, and crush to 16 mesh. The pulp from the latter goes to classifiers, the coarse sand passing to the sand-vats, and the fine to the tube-mill. The product of the tube-mills is classified by cone-sizers, the overflow passing through a settling device, thence to the slime-plant; the underflow is re-ground in the tube-mill, and then goes to the slime-plant, in which all pulp treated is 200 mesh or finer. The sand is 80 mesh size. The sand-treatment consists of three washes, each of cyanide solution containing 6 lb. KCy per ton of solution, followed by three washes of a $4\frac{1}{2}$ -lb. solution, then by four washes of barren solution, and finally a water-wash. The first six washes consist of 33 tons of solution each, the charge of sand being 120 to 130 tons. The slime-plant consists of 6 main-tanks, 2 collecting-vats, and 4 agitating tanks. The slime is subjected to agitation for 12 hr. before it passes to the main-tanks. The strength of the solution used is $2\frac{1}{2}$ lb. KCy per ton of solution. After being settled in the main-tanks the solution passes through Butters filters to the precipitating boxes. The ore thus treated contains 7 to 8 oz. silver, and \$6 to \$7 gold per ton, making an average of about \$11 per ton. It is stated that the extraction amounts to 75% of the silver, and 85% of the gold. The silver is mostly present as argentite, and the gold is associated with it. The company has leased and is operating the old Grand Central mill, which now belongs to the Butters Co. It is handling 180 tons of tailing per day that accumulated at the old Colorado mill when the latter was operated as a Boss continuous pan-amalgamation plant. This tailing is said to contain about \$8 per ton in silver and gold. It is

the Florida district of the Rand) contains numerous points of novelty and interest. The idea has been worked out by W. K. Betty, who appears to have obtained the keen support of W. W. Mein, general manager of the Central Administration mines, to which group the Bantjes belongs.

The scheme in its initial stage embodies the idea, not yet attempted upon the Rand, though put into practice elsewhere, as in the Waihi mill, New Zealand, of establishing an amalgamation-house apart from the battery. The advantages of this system are several, and have often been discussed in technical writings. Not only is time saved by the continuity of full crushing when plates are being dressed, but the dangers of theft are materially reduced. The change fits admirably into the recent plan of employing only white men in places where gold—in amalgam or slime—is actually handled. According to the present proposal, the extractor-boxes and the plates will be under the same roof, further minimizing the risks of gold-stealing. To what extent the mills are robbed by dishonest employees, it is impossible to suggest. Judging by actual convictions, the amount taken is small, but unfortunately the police records have in the past provided an inadequate guide for the estimation of the Rand's 'undeclared output'. It is certain that companies can afford to bear considerable expense for the purpose of checking the illicit buying of gold.

The Bantjes scheme, in its first stage of development, goes further than this centralization of gold-recovery. In order to obtain higher stamp-duties, with tube-mills as auxiliaries, it has been necessary on the Rand to adopt coarser and coarser screening. The particles thus liberated from the boxes are consequently of such a size as to have an undesirable scouring effect upon the tube-mills, and the

shaking amalgamating tables. A big proportion of the stamp-battery product will therefore be cyanided, as sand or slime, without previous amalgamation, while the coarse sand will be separated by means of the usual spitskasten for re-grinding in the tube-mills. A certain amount of coarse free gold may be caught below the stamps in the launder which carries the pulp to the pumps used for elevating to the classifiers, in the same manner as in a riffleless sluice-box. In any case this could not be lost. The plant being erected at the Bantjes is of a comparatively small capacity (10,000 tons per month, on an estimated stamp-duty of 10 tons per day) and the advantage of economy of labor in this case will be of small account. In a large plant, however, the scheme would result in a substantial saving in costs of supervision.

That the above ideas will be put into practice, as soon as the Bantjes reaches the producing stage, is assured; but it is possible that the occasion will be seized for working on still more original lines. It is tentatively proposed to attempt gold-recovery without employing the amalgamation process at all. The plant would then comprise 35 stamps weighing as much as 1650 lb., a tube-mill, and a sand and slime plant, with essential classifiers. The Adair-Usher process of slime-treatment would be employed to facilitate operations. Such an experiment would involve no abnormal risk, for, if unsuccessful, shaking plates could be easily introduced below the tube-mill to bring the sequence of units into the range of proved practice. If the Bantjes company undertakes the experiment at its own cost, however, it will be performing pioneer work of a promising character, meriting the thanks of all Rand metallurgical engineers. Although technical gratitude is long-lived on the Rand and well appreciated by those who win it, there seems to be no objection to the proposal that such experimental work should be undertaken with the financial support of the lately-constituted Mines Trials Committee under conditions which would give the industry as a whole the greatest possible benefit from the lessons derived.

The Government Mines Department has published its monthly statistics for December, so that the records for 1908 are now complete. In spite of a heavy fall in the value of diamonds produced, owing to the market weakness, the aggregate output of all minerals for the Transvaal shows a satisfactory increase as compared with the figures for 1907. The declarations for the two years stand as follows:

	1908.	1907.
Gold	£29,980,526	£27,400,992
Diamonds	1,549,815	2,268,075
Coal	794,949	773,649
Base metals	246,766	192,296
Silver in gold bullion....	85,032	91,893
	£32,657,088	£30,726,905

According to these statistics, the increase in gold yield is £2,579,534, and the decrease in the value of diamonds, £718,260. Forecasting the future development of the various mineral industries, the most confident prediction which may be attempted is that the output of gold and its associated silver, and of base metals—notably tin—will increase steadily for some years to come. Apart from the favorable indications attending prospecting in several areas, which give promise of increased tin production in the near future, strength is given to the assumption of a greater output of this metal by the more advanced operators of the Weynek and the Rooiberg companies in the Waterberg district. The former venture commenced milling on a small scale recently, and the latter promises to become a producer in March next. The expansion of the diamond industry is dependent solely upon the market. Shortly, new plant will be erected at the Premier mine, giving the company a producing capacity of about twice its present standard.

The future of the coal mines has been rendered less promising by the recent announcement of the Victoria Falls Power Co. to the effect that, through an important amalgamation of interests, it has secured contracts for supplying all the mines under the Eckstein control with electric

power. In a couple of years the steam-plants on these properties will be maintained merely as auxiliaries in case of break-downs, and will eventually be discarded. The contracts obtained render it safe to lay down a new power-station with an initial capacity of 90,000 kw. This will supply companies treating, at the time of the station's completion, seven or eight million tons of ore per annum, and it is estimated that the scheme will save the consumers in power-costs 8d. per ton of ore milled. A subordinate part of the scheme involves the erection also of three central compressed-air generating stations on the Rand.

The electrification of the Rand began three or four years ago upon certain mines in the Germiston district. With the completion of the present scheme, a great advance will have been made toward the ideal steadfastly advocated by electrical men upon the field for many years, namely, the utilization of electricity to a maximum degree in all the major branches of power-consumption. It is to be hoped that the Victoria Falls Power Co. will now change its name so that the mistaken idea may not get abroad that the former scheme of serving the Rand mines with electricity generated at the Zambesi river has been carried into effect, though there is still hope that the vast Rhodesian fall will be harnessed for service in Charterland. Existing power-stations are situated where coal can be cheaply obtained to operate the prime-movers and the new station will be within thirty miles of the Central Rand.

The Rand's accident rate for the past year shows a gratifying decrease as compared with 1907. A broad classification may be arranged comparatively as follows:

	1908.		1907.	
	(Total employees, 180,000.)		(Total employees, 160,000.)	
Accidents due to:	Killed.	Injured.	Killed.	Injured.
Fall of ground.....	204	245	197	221
Explosives	209	177	280	263
Miscellaneous	299	644	333	576
	712	1066	810	1060

Unfortunately the current year has commenced unpropitiously from the accident point of view, and the record to date has been rendered exceptionally unfavorable by the occurrence of two or three serious disasters. On January 22, during a sequence of abnormally heavy rains, the dam of the May Consolidated burst and, carrying with it the Glencairn's old slime-dam, poured as a great wave down into an old prospecting shaft on the northern outcrop of the Witwatersrand gold mine (commonly known as Knight's). The mine speedily filled with water, and almost every man at work below was believed to be drowned. Until all hope has to be abandoned by the actual recovery of the men's corpses, however, every effort will be made to de-water the mine and explore every possible place where refuge may have been taken. Owing to the rapidity of the occurrence, little hope of saving life was entertained. On January 29, the pluck and determination of the management, however, was rewarded by a wonderful discovery. In a small back-stope, from which the water had been excluded by the pressure of the confined air, 25 natives were found alive after seven days foodless imprisonment. Their physical condition must be described as little short of miraculous and has been a surprise even to those with the most intimate knowledge of the Kaffir's powers of physical endurance. Three of the 'boys' even anticipated the labors of the rescue party by swimming for some distance along the drive—though one of these sank with exhaustion. The others, after receiving nourishment, speedily regained strength and vitality, and begged to be allowed to return to their fellows in the compound before such a request could possibly be granted. One of the Kaffirs, who had been entombed in an isolated place, made his way to the mine captain's office upon reaching the surface to enquire anxiously if his 'ticket' would be duly signed for the seven double shifts he had spent below. Up to the time of writing (Jan. 31), 25 men and 26 bodies have been recovered, out of the 160 working below at the time of the disaster

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Mexico contains 20,000 Americans, who are engaged in enterprises involving a capital expenditure of \$900,000,000.

Epigenetic deposits of ore are those which have resulted from replacement or alteration of rocks and minerals. Similarly the term is applied to any mineral which has been derived from the alteration of another.

Platinum has been found in quartz veins in gneissoid syenite, associated with gold, near Santa Rosa, Antioquia, Colombia. This occurrence has been known for nearly a century, and was described by Boussingault.

Copper at Corocoro, Bolivia, occurs in Permian sandstones and conglomerates, the metal being in metallic form. The distribution of the copper is not uniform through the deposit, which offers an obstacle to economical mining. The ore is accompanied by gypsum, and in the lower parts of the bed native silver is found.

Latest additions to the table of atomic weights by the International Committee are two in number. Urbain, a French chemist, has proved that ytterbium is a mixture of two elements which he has named neoytterbium and lutecium, the former having an atomic weight of 172.0, and the latter 174.0. There are now 81 elements recognized by the Committee.

Steam turbines are considered to offer the following advantages over reciprocating engines: they develop high efficiency at low loads; their rate of rotation continues uniform, decreasing the liability of 'hunting', and lessening the strains on the foundations; smaller size, weight, and space for equal power; and lessened cost for attendance, maintenance, and repairs.

The point system was adopted in 1883 by the Typefounders Association of the United States, to introduce a unit of measure whereby types from different foundries might be made interchangeable. With the introduction of this system the old names of typebodies were abandoned; for instance, brevier became 8-point, and long primer, 10-point. These columns are printed in 10-point, and 72 points are equivalent to an inch.

Burnt clay roads are made by laying brush wood to a suitable depth on the surface, and then throwing the earth from each side upon the bed of fuel. The clay after being burnt loses its power of becoming plastic, and will sustain vehicular traffic without cutting into deep ruts, as happens in clay lands where such treatment has not been given. The clay will often vitrify to some extent, giving a gravelly texture to the surface. When vitrification occurs the artificial road-metal produced possesses superior efficiency. Such material has been used with considerable suc-

cess as railroad ballast, although some disappointments have attended its use for this purpose.

Gold-bearing gravels cannot be tested by shafts when water is found rising to any considerable height above bedrock, without large expense in coffer-dam construction. Even then, the tendency of sand to run in from the sides is great. This will carry gold into the shaft and falsify the sample to an extent which cannot be estimated. Under such situations the drill-samples must be relied on, and safety reached through multiplicity of drill-holes.

Calamine violet is the name given to a variety of the crow's foot violet which changes its natural brilliant blue color to an equally brilliant yellow when zinc is present in the soil. It is one of the few well established instances of alterations in the color of flowers due to metallic salts. The subject might properly engage the attention of some of the Experiment Stations in the West. Other like relationships might thus be proved to have significance for the prospector.

Determination of the degree of concentration effected in the milling of a uniform ore may be rapidly done with a fair approximation to accuracy by the use of the specific-gravity bottle. Knowing the weight of the bottle filled with water to a graduation-mark on the neck, a sample of the dried concentrate weighing 5 to 10 gm. is introduced into the bottle, and distilled water is then added until the meniscus rests on the graduation line. The bottle with its contents is then weighed. The specific gravity of the concentrate is then calculated from the formula:

$$\text{sp. gr.} = \frac{W}{(W + A) - K}$$

where W = weight of concentrate taken.

A = weight of bottle filled with distilled water.

K = weight of bottle and concentrate, with water filled to graduation mark.

Adiabatic curves are the graphic representation of the relation between the pressure and volume of a gas during its change of volume through expansion or contraction without absorbing or evolving heat. When adiabatic lines cross isothermal lines they are always inclined to the horizontal at a greater angle than the isothermal lines, because as the gas expands the pressure diminishes more rapidly than for an isothermal line, since the temperature is reduced by the work done in expanding under pressure. When air is compressed without cooling it is said to be adiabatically compressed, and under such conditions the pressure rises in more rapid ratio than the volume of the air diminishes. Therefore the power required is greater than when, by means of cooling, the air is compressed so as to approximate a uniform temperature throughout the operation, that is, isothermally. Neither form of compression is attainable, the net result being a combination of the two. The relation between the curves of actual compression and the ideal adiabatic and isothermal curves, is an indication of the mechanical efficiency of the compression.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Mr. Ralston and the Institute.

The Editor:

Sir—Two surprises awaited me on Saturday last: one that I had been nominated for the office of Vice-President of the American Institute of Mining Engineers, and the other that the MINING AND SCIENTIFIC PRESS objected to me personally on grounds stated. I feel constrained to answer your editorial, much as I dislike newspaper controversy on personal matters. Why you should protest against my nomination seems to me rather strange, if only in view of the fact that I have been a full member of the Institute for the past nineteen years and have already served one term in 1900-1901 as Vice-President. Eligibility for membership in the Institute naturally means also eligibility for holding any of its offices. It is not confined to mining engineers only, but to "all professional mining engineers, geologists, metallurgists, or chemists, and all persons practically engaged in mining." I may say that up to four years ago, when for two years I accepted the presidency of the Fulton Iron Works, I had followed the business of mining for a period of nineteen years. During that time I served my apprenticeship as ditch-tender, surface and underground miner, shift-boss, foreman, superintendent and manager of both gravel and quartz mines, constructor and operator of mills, etc., and am still interested directly in legitimate mining. I am at present, among other things, a director and treasurer of one of the most productive gold mines of the world, and sharing its active management. It is true that I am not a graduate of any school of mines, a fact which I regret more than anyone else can, but I was obliged to go to work and earn my own living at the age of sixteen, a few years after the death of my father, first starting as a helper in the assay-office of the Selby Smelting & Lead Co. I subsequently went to work as a miner in Placer county, and after that took a special course in mining in the University of California for six months, which was all I could afford at the time. I recite these facts merely to show that I have been "practically engaged in mining," which is one of the requirements for membership in the Institute.

I fancy I may have been selected by the nominating committee as a candidate for Vice-President merely for the reason that they wished someone from the far Western mining States. I was not an applicant for the honor in any manner, nor did I know of their action until I read of it in your paper.

You say I am "a politician and a broker," which is true, and seem to consider that this should effectually dispose of any claim I might have for the office in question. I see nothing to be ashamed of, for in my opinion if more men would talk less about

reform and serve their States in the Legislature properly, we would have less vicious legislation. As a politician, I had the honor of being chosen Speaker *pro tem* of the Assembly; of being Chairman of the Committee of Mines and Mining; and the ranking member of the Ways and Means Committee. The following session, as a member of the State Senate, I was appointed Chairman of the Committee on Mines, and during my term was a member of the committee of five who commenced the real reform movement against graft by recommending the expulsion of four Senators for receiving bribes, which recommendation was concurred in. I confess I feel somewhat proud of my record as a politician and intend to continue my interest in the public affairs of my City, State, and Nation. In my way of thinking, the man who takes no interest in politics is not a good citizen.

For the fact that I am a member of the San Francisco Stock & Exchange Board I have no apology to make, nor is it necessary. A market value for the shares of the mining corporations cannot well be established except by listing them on stock boards. Of course all stocks so listed do not necessarily have intrinsic value, and some changes in methods would improve the business. No one has tried more earnestly than I have to bring about such changes. The business of a mining stock-broker is as legitimate and honest as any. If it be wrong to buy and sell mining shares on commission, it is also wrong to buy and sell them for personal profit. Yet I have among my clients in the purchase and sale of mining shares, some of the most distinguished mining engineers on this coast and elsewhere. It may then be also wrong to advertise the prices brought by the purchases and sales, yet your paper prints these quotations weekly, obtained I may incidentally remark, from my own office. If there be anything morally wrong in any part of this business of mining share dealing, it is wrong in all, but this I deny. Of course there may be dishonest brokers as well as dishonest mining engineers, but neither business should be condemned for this reason.

You have always seemed to enjoy 'taking a fling' at the California Miners' Association. Let me say that in the past this Association has done much for the mineral industry of this State and in the near future will doubtless be called upon to prevent vicious legislation. While little or nothing has been accomplished in the past two years, yet the strength of the Association may be shown at very short notice when occasion arises. The Association merits the assistance of a paper like yours, rather than adverse comment.

I wish to be permitted to say that you are utterly and unqualifiedly mistaken in your conclusion that I "depreciate and repudiate mining engineers as a guide to the development and operation of mines." I never made any such statement, nor am I a believer in it. You have doubtless heard me say "that the tendency of the average School of Mines graduate is a desire to start in as a boss and is unwilling to start in at the bottom and gain some practical experience; that he is generally of an age when it is objec-

tionable to him to perform the labor of a miner." I have said this and repeat it.

I was born in San Francisco and raised in California, and while my education has been of the mountains and my advancement slow, yet my reputation and standing in the mining world, such as it may be, I think permits me to call myself a mining engineer fully as much as others who are not at the present moment following that line of work.

W. C. RALSTON.

San Francisco, February 1.

[The following correspondence is published in order to explain the delay in the appearance of Mr. Ralston's rejoinder.—EDITOR.]

Mr. W. C. Ralston.

Care of Mr. J. D. Irving,

Yale Univ., New Haven, Conn.

My dear Ralston:

Your letter in reply to my editorial arrived after we had gone to press with the part of the paper in which it would naturally appear, that is, the Discussion department. Therefore, I held it over for this week. In the meanwhile, Mr. Kinsman came to see me, and I received a letter from Mr. Benjamin. This morning, Mr. Creswell was here, and I had a long chat with him. He authorized me not to publish your letter thinking that it was to your interest that it should not be published, for I told him that if I did publish it, I would have to give chapter and verse for my statement that you repudiated the mining engineer as a factor in mine development. My authority is Mr. De Kalb and another friend to whom you spoke rather carelessly, saying that you had no "damn use for a mining engineer's report." and that when you had a mine to sell, you would not have a mining engineer examine it, etc.

As the controversy is not with you, but with the powers of the Institute for the irregularity of their method of nominating officers, I was glad to accept the suggestion of Mr. Creswell that your letter be not published. The letter is an excellent one, and makes a good retort, and I would have been very glad to have published it except for the last paragraph but one, in which you deny the accuracy of a statement of mine, for which I have ample evidence.

Trusting that you will absolve me from any personal motive in this matter, I am,

Yours faithfully,

T. A. RICKARD.

San Francisco, February 8.

T. A. Rickard, Esq.,

667 Howard St., City.

My dear Mr. Rickard:

When in the City of New York I received telegrams from some of my friends in this city suggesting that my letter to you of the first day of February, 1909, should not be published by you. Having other matters at the time to think of, I requested Mr. Creswell to see you and use his own judgment in the premises. Since my return I have been unable to take up this question before today.

I am writing now for the purpose of informing you

that after inquiring into the whole subject matter, I see no reason why my letter to you should not be published in your paper as a reply to your editorial. I would be pleased to have you publish it as written if you will kindly do so.

Yours truly,

W. C. RALSTON.

San Francisco, March 4.

Geological Hierophants.

The Editor:

Sir—I have laughed with you at the verbal singularities of that scrap of petrographic literature over which you made merry in a recent issue, but one may laugh and not agree. There are many, however, who will not only laugh at the playful humor of your editorial, but will seriously accept your pleasantries as a denunciation of the efforts of technologists to describe a rock in accurate terms without having to write a chapter to avoid mistake. The common names of rocks are misleading; even when qualified as to predominant accessory minerals, they fail to convey definite ideas of composition and structural peculiarities. It is by no means certain, for example, what character of rock is implied by the term anorthosite. The tendency would be to think of the type-rock, composed almost exclusively of labradorite, although close conformity to such an ideal is rare through extensive areas. The rock is almost certain to approximate the gabbros, and a mineralogical description would be necessary to convey accurate information of its composition. The thing to aim at in description, whether it be scientific or popular, is to use terms adequate for the purpose. If one refer to a dike cutting a certain formation, and the point at issue concerns structural relationships, it would reveal a pedantic streak in the brain to call it a dike of augite-basalt-porphyry, when basalt would be quite enough for the purpose; but if it be intended to call attention to related physical phenomena the fact that it was a porphyritic augite-basalt or melaphyre would be important: it would indicate more narrowly the composition of the original magma, and some of the circumstances attending its consolidation, which would at once call to the mind of a man competent to appreciate the practical significance of the record probabilities of more extended relationships. If the important point be the approximate chemical composition of the rock, it may be stated in the form of a chemical analysis, which might be misleading because too exact to cover the unavoidable variations within a magma of any size; it may be stated cumbrously in so-called plain language which would promptly involve the description in obscurity through mere verbosity; or it may be systematically described by terms of precise meaning according to the system which you have made the subject of jocular remarks. In Professional Paper 62 where a syenitic rock is described by the system of mineralogico-chemical analysis the characteristics accurately indicated are important. In other parts of the report other terms sufficient for the purpose are employed.

The almost hopeless confusion which has existed

in petrographic classification, resulting from the complexity of the subject, was the moving cause for the effort at reform on rational lines. It is a cardinal principle that the old familiar words of common speech are unsuited for exact technical definition because they are inevitably taken with a tincture of the old meaning. Thus the committee on quantitative rock-classification wisely introduced new and unfamiliar terms with definite significance, but so suggestive of names in common use as to indicate well understood relationships. It certainly marks a long step in advance over any system previously employed, and tends to deliver petrographic descriptions from chaotic confusion.

The pity of scoffing at the employment of accurate nomenclature where such decisiveness be necessary is that it serves the purpose of those whose joy is to cast aspersions upon the economic geologist, in order that nefarious schemes may be promoted under cover of hazards taken in the dark. Wild-cat promoters do not wish the revelations of science; they care not for truth; they care only for the money of the gudgeons; and the jesting of a technical editor, making ridiculous the efforts of economic geologists to say what they mean in unequivocal terms, plays directly into the hands of those whose practices you have ever stoutly condemned. Your 'Geological Hierophants' must have been written in a moment of inadvertence.

NORM.

San Francisco, March 2.

[This is a reasonable protest, and if Professional Paper No. 62 had been intended to form part of the proceedings of a scientific society, it would be conclusive. But the publications of the Geological Survey are not addressed to scientific men only, or even largely; they are made under an appropriation from Congress with the idea of proving of general service to those engaged in the development of the mineral resources of the continent. As thus regarded, one cannot forbear from seeing the humor of such a hierophantic performance as that quoted from No. 62. Imagine a mine superintendent at Wardner lighting on the offending paragraph—it is fit subject for a cartoon! At the same time we appreciate the value of terms of precision and admire writers who try to use them in a scientific manner. If read to an audience of mineralogists that description of the syenitic rock in the Coeur d'Alene would be admirable; as a means of imparting information to those engaged in mining operations, it is absurd. —EDITOR.]

Fink Process.

The Editor:

Sir—In a recent issue you make a statement concerning the Fink process, as follows: "At 10 o'clock Saturday night January 16, the first pouring of blister copper ever made in a single process furnace was accomplished at the Edward Fink plant at Garfield, Utah," etc. While not wishing in any way to detract from the value of the results attained by Messrs. Fink and Newhouse with their new furnace, I still think the statement made is an error, as J. E.

Knudsen at Sulitjelma in Norway has for several years been operating a converter on ore direct, producing at will either high-grade copper matte or blister copper. This plant has been inspected by many of our best copper metallurgists and their reports as to the efficiency and capabilities of the method are on record. In Mr. Knudsen's furnace, which is a simple style of 'converter', the ore is charged onto a small body of fuel, either slack coal or wood being used; the blast is introduced through suitably situated tuyeres, and thereafter until the pouring of matte or copper the combustion of the sulphur and iron furnishes all the heat of the smelting process. Mr. Knudsen does not pretend to make a clean slag at this one operation; he pours the slag or transfers it to a settling-furnace where it has a chance to clear itself of mechanically contained shots of metal or matte. The costs of the Knudsen method are to be had on inquiry, the Metallurgical Co. of America being the representative for this country. I do not think that Mr. Knudsen claims to treat fine ore, concentrate, or slime, with success; a large percentage of such material would naturally interfere with the reactions in the vertical converter, or would be lost, temporarily at least, in the gases.

The Knudsen plant is not running as an experimental or test plant but as a regular smelting operation every day; the ores are pyritic, carrying from 3.55 to 6.31% copper, 32 to 34.5 iron, 24.4 to 29.1 silica. The matte resulting from these charges carries from 45 to 72% copper and is as a rule poured and taken to regularly operated converters. This is done because it is found cheaper to carry out the process in two vessels and in two stages, rather than to confuse the reactions in one vessel by attempting to perform two operations either together or consecutively. The slags from this operation carry, after settling, about 1% copper and 35.5% silica.

Ralph Baggaley of Pittsburg has patented a horizontal smelting vessel, or converter, lined with basic brick, in which he proposes to carry on both the smelting and converting reactions, the latter at least in part; this furnace, however, was not built and tested in Butte at the time Mr. Baggaley's other inventions were tried out, therefore we cannot give him the precedence in this matter. Verily it sometimes seems that "there is nothing new under the sun!"

JAMES W. NEILL.

Pasadena, March 1.

Progress in Cyanidation.

The Editor:

Sir—In your issue of January 30, I notice the appreciative reference of Capt. Francisco Narváez, of Pachuca, to my article upon 'Progress in Cyanidation', and note that Capt. Narváez now does all his crushing by Chilean mills. This is interesting news, and I hope he will give us the benefit of his most recent results, including wear and tear, working costs, horse-power, consumption, fineness of original feed and of crushed product. It will probably interest him to know that his work is being keenly followed elsewhere, and that in Rhodesia particularly

Chilean mills are being largely employed. My reference to soft ore is evidently due to a misunderstanding of his precise expression when he was so good as to personally give me details of his work. The feed to the Chilean mills was obviously finer than that sent to the ball mills, as Capt. Narvaéz now confirms, and I understood him to say it was also softer. The correction apparently makes my statement as to the work of his mills all the stronger, for it now appears that he is able to crush 15 metric tons per diem for a consumption of 10 hp. from 1½ in. cube to 80% through 200 mesh at a cost, including 10% depreciation, of 0.7 peso (17¼d.) per ton on the general average rock produced by his mine. Possibly these results have already been improved on by him.

ALFRED JAMES.

London, February 17.

Titular Prefixes.

The Editor:

Sir—I note your remarks on the misuse of titular prefixes, in the issue of the 20th inst., in all of which I fully concur. In the note immediately preceding, you speak of Senator Henry M. Teller. Would it not have shown greater consistency if you had referred to that gentleman as Mr. Henry M. Teller, United States Senator for Colorado?

A. JEWELL.

Berkeley, February 22.

[Yes; "consistency is the jewel of small minds."—EDITOR.]

Researches in Diamond Making.

The Editor:

Sir—Referring to Mr. D. Mosher's letter in your issue of the 20th inst., concerning my article on 'Researches in Diamond Making', appearing in your issue of December 5, 1908, I think he has not quite followed the drift of the article. I did not understand, nor was it my intention to convey to the reader that Mr. Threlfall used the excessive temperatures, in his experiments, with the idea that diamonds would crystallize at those temperatures; but rather, that the high temperatures were used to insure the liquefaction of the carbon, in the hope that as it cooled—under excessive pressure—it might re-crystallize in its most beautiful allotropic form. It was this idea that I hoped to convey to the reader when I wrote: "The ideal condition, as Mr. Threlfall points out, would appear to be the heating of carbon at a high temperature for a short period with some substance with which it is soluble, and then maintain it at a temperature at which carbon would begin to separate for a long period, and keep it under a high pressure the whole time."

While graphite, under comparatively low pressure (less than one ton per square inch), and at no greater temperature than is caused by its compression, is known to behave physically like a fluid, it cannot be considered, chemically, to be in the liquid state. There would be little hope of its re-crystallizing, upon solidification, in any form other than that in which it existed prior to liquefaction. That diamonds may,

however, crystallize at a high temperature is evidenced by the fact that Moissan, in his successful experiments, heated highly carburized cast-iron with carbon in the electric furnace, and quenched the product in molten lead. The iron was afterward dissolved in nitric acid to which chlorate of potash was added; the residue was treated first with caustic potash, and then to prolonged boiling in hydrofluoric acid, followed by similar treatment with sulphuric acid, and finally fusion with caustic potash. The residue remaining from this treatment was carbon—but in the form of diamond. The largest diamond Moissan produced was 0.5 mm. in diameter.

F. H. MASON.

Paso Robles, California, February 22.

Smelter Fume.

The Editor:

Sir—At many smelter-sites the wind blows the greater part of the time from one direction, that is, there is a 'prevailing wind'. It will be observed, when the wind is blowing at a considerable velocity, say, 10, 20, or more miles per hour, that the fume from a smelter will be mixed with a large volume of air, and will be but little noticed in the country over which it passes. If, on the contrary, only a light wind be blowing, or a calm prevail, then the fume is but little diluted, the atmosphere becomes heavily charged with fume, and damage results. With sufficient dilution harm from smelter fume may be largely avoided. This idea may be applied practically. From the site of a smelter, construct a conduit at right angles to the direction of the prevailing wind, in one or both directions, for such a distance as may be required; depending upon the amount of fume produced. At intervals of 100 ft. provide openings from which to permit a small portion of the fume to escape. Thus in the distance of one mile there would be 52 openings from each of which a small amount of fume would escape. Suppose that in the case of a large smelter 10 miles of such conduit would be required. Then there would be 528 openings, from each of which a small amount of fume would escape, and the fume would be subjected to extreme dilution, so that no harm could ensue.

Those who have lived in the vicinity of large smelters will have observed that with a constant wind in one direction, the fume will be carried away with but little spreading out of the smoke-stream. In a distance of 12 or 15 miles I have frequently observed such a stream to be no more than half a mile wide, and still capable of injuring susceptible vegetation. If this volume of fume were emitted through a conduit 5 or 10 miles long, a small amount escaping through each of a number of openings, extreme dilution would result, and no harm could follow. The smoke-stream would be 5 or 10 miles wide at the beginning. Such a conduit would not need to be of large size, since the fume would be forced by blowers at high velocity. The conduit, moreover, would diminish gradually in size.

L. F. BASSETT.

Redding, California, February 25.

MINING METHODS IN THE NORTH.—III.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

'Drifting' aided by steam-thawing is the mining method characteristic of Alaska and the Yukon. It deserves detailed description.

On the claim known as No. 11 Below Discovery on Cleary creek, near Fairbanks, I had an opportunity of seeing this method applied in a systematic fashion. Henry Riley was in charge of the operations and gave every facility to observe the work in progress. The shaft is 7 ft. square and 70 ft. deep. It is sunk several feet below bedrock so as to serve as a sump for the drainage of the mine and afford the gradient necessary for the easy movement of the cars. To this one shaft comes all the product of the mine, both water and gravel. The former is pumped to surface; the latter is raised in a self-dumping bucket. Fig. 1 gives a plan of the workings, looking up-stream. As soon as the shaft has been sunk, a main level is started in both directions along the creek-bottom. An area 360 ft. long and 250 to 300 ft. wide is then blocked out, preparatory to extraction. Going up-stream the main gangway was 200 ft. long, while in the opposite direction the limit was the old workings. As the sketch shows, the removal of the gravel had resulted in the formation of cavernous openings. At the upper end, two pillars (D and E) had been left in place to hold the ground. Stopping was progressing on each side of the main level, toward the shaft, as indicated by the arrows. From 6 to 7 ft. of gravel is removed and also 1 ft. of the bedrock on which it lies; thus the excavation or room is 7 to 8 ft. high. As the gravel is extracted, the roof thaws, drops, and forms a flat arch. The material falling from overhead forms a slope inclined at about 7° and leaves a void about 5 ft. high, as against the original 7 ft. in the stope. Since the ground when broken should occupy about $1\frac{1}{2}$ times the space it filled before removal, it is a fair inference that the ice in the gravel must represent about 50% of its total bulk, for it is the melting of the ice, and its removal as water, that prevents the caved ground from filling the stopes.

Thawing is done with steam-points. A battery of them in action is shown in the accompanying photograph. They are applied in groups of four or five, united by a cross-head, with a valve for each 'point.' In Fig. 1 the position of steam-points is shown by small stars. The space at A has no points; it is a 16-ft. pillar left to support the roof. In the near stope to the left there were 38, and in the right-hand stope 42, points. The driving of the points is effected with hot water, fed by an injector at about 150° F., so as to keep the aperture clear at the working end. The point is inserted into the gravel just above bedrock and driven forward gently by the tap of a hammer as a way is made by the thawing of the ground. The use of hot water minimizes the amount of steam in the workings and tends to diminish caving. After the points are in position and have been driven to their full length, the steam is turned on. Steam is

then passed for 24 to 30 hours. This is the 'sweating' period. If the point is working well, no steam will be seen escaping at the head, for all that is entering the pipe is being emitted at the inner extremity, where the work of thawing is being done.

When the ground has been thawed in this way, the 'points' are removed to another place in the mine and the work of extracting the softened de-

Fig. 1.

posit begins. The gravel is broken with a pick, and shoveled into wheelbarrows. At C and B, where the cross-cuts meet the main level, there is a landing; here the wheelbarrows are emptied into a car, which transports the material to the shaft. The bucket comes to rest below the floor of the level and

Fig. 2.

the car is discharged into it. The men trundling the barrows have to maintain a regular gait, for there are six of them on each side and they have to advance in procession. Each man picks, shovels, and wheels his own share of the gravel. At the time of my visit, on August 5, the total force numbered 44 per day; of these 30 were working in the mine. The miners are paid \$5 and board; the hoist-men, \$6 and board. Two point-men work 10 hours by day and one point-man works for the same length of time by night; each of these is paid \$7 and board. Board is worth \$3 per day. All the main gangways are tim-

bered, but there are no collar-braces. The top and sides are lagged with round poles.

The method of mining is fundamentally a modified long-wall system, the ground being allowed to cave in the rear as the working-face is advanced. The air is like that of a cold-storage plant. As the visitor goes through the workings he hears and feels the effects of the thawing, for the distant thump of dropping gravel may be accentuated by a tap on his own shoulder as a pebble performs the duty allotted to it by the immutable law of gravity. To avoid danger, it is well to keep close to the frozen face and avoid all cavernous spaces. The use of a steam-point, as compared to the old wood fire, localizes the thawing and does not heat the air of the workings so as to cause the arch to collapse too fast. When burn-

workings is shown in Fig. 3. The shaft is 88 ft. deep to bedrock and is then continued 12 ft. deeper into the bedrock, so as to facilitate drainage and grade. The main drift A B runs up and down the longer axis of the gravel deposit lying on the creek-bottom. Cross-cuts E F, G H, K M, C D, are extended at regular intervals to the limit of the pay. The shaft is 6 by 6 ft. in the clear; the drifts are 6 ft. wide and 6½ ft. high. Bedrock is soft schist; in places it has been disintegrated to the condition of clay. The gold has penetrated the bedrock; in places it is profitable to dig 18 in. The alluvial deposit is topped by 30 to 40 ft. of muck, most of it being ice. The underlying gravel and débris carries a little gold all the way down to bedrock, but on the bottom there is a layer rich enough to warrant extraction. A thick-

Steam-Points in Action Underground.

ing wood, the air was warmed and the roof of the working tended to cave suddenly. But at its best this thawing with steam is a dangerous method. It is necessary to take chances, for the presence of interstratified layers of ice may cause big slabs of gravel to fall. As a rule the cracking of the ground affords a warning. Protection for the miners could be obtained by using a stull with a head-board, at intervals, where gravel is being removed. This temporary timbering could be pulled out as the work progresses.

Any gravel supposed to be worth less than 2 cents per pan, that is, \$2.75 to \$3 per yard, was not mined. This was stated to be the economic limit.

A few days later, on Esther creek, I saw several good examples of this type of mining. One of the best was on the Reutter fraction next to Claim No. 3 Below Discovery. John Jesson was in charge and explained his operations clearly. A sketch of the

ness of 3 to 7 ft. is mined. The width, across the creek-bottom, reaches in places to a total of 600 ft. and it is doubtful whether it does not connect with a bench deposit that is 400 ft. more. The mine, as I saw it, had workings reaching laterally for 180 ft. and lengthwise for 250 ft. The intermediate cross-cuts (G H and K M) are called 'emergency tunnels.' In case the main stopes are lost, by reason of caving ground, so as to stop extraction, these additional avenues enable a new working face to be started. Extraction proceeds in a wedge-shaped room or stope, the outer end (as at G, N, O, and P) being kept far ahead of that portion of the stope which abuts against the main gangway. The purpose of this is evident: it protects the main artery of the mine and also the main entrance (the shaft). When the block of ground is worked out there survives a diamond shaped or rhomboid remnant around the shaft. Successive advancement, as the stopes enlarge, is indi-

eated by the dotted lines. In case of a cave, such as is illustrated by the area A B C D in Fig. 4, a new cross-drift, E B, is driven from the main gangway, in order to reach the uncaved part of the stope.

Steam-points are used in the ordinary way. From 35 to 40 of them are inserted in the face of one room, while picking and shoveling is going on in the three other rooms or stopes. The points are placed 2 to 2½ ft. apart.* They are 8 ft. long and thaw the ground for 2 ft. beyond their inner extremity. They thaw a thickness of 4 to 5 ft. Therefore the duty of each point is 100 cu. ft. or nearly 4 cu. yd. They are allowed to sweat for 24 hours. While the point is being driven into the gravel, it is fed with water forced by a Worthington pump and having a temperature of 120° to 200° F.

The air underground is chilly. In one stope I saw a layer of ice on the bedrock. In vertical seams traversing the overlying gravel, I saw slabs of ice projecting. The clear ice melts slowly and survives after the frozen gravel has disintegrated.

The force engaged in this mine during the day shift consisted of 18 laborers at \$5, 1st point-man at \$6, 1 man at the dump-box at \$6, 1 man at the boiler at \$6, 1 foreman at \$10; while at night there were 1 point-man at \$7 and an assistant at \$6; also 1 boiler-man at \$5. In each case the cost of board (about \$3) must be added to the wages specified, for the operator feeds the men, and he feeds them well. Most of the thawing is done at night. Wood costs \$8.50 delivered and 5 cords are used in the 24 hours.

There were 22 men underground at the time of my inspection. Each laborer engaged in moving gravel is expected to make 100 trips with his wheelbarrow in his 10-hour shift; this is equivalent to 10 cu. yd. The barrow-men come out of the stope in regular order, in three crews of six each. Six barrows fill a bucket. The bucket-tender at the shaft pulls a wire that rings a bell in the main drift and this serves as a signal notifying the barrow-men when they are to start in procession toward the shaft. This is so timed that the loaded barrows meet the bucket on its descent; thus the whole performance is intelligently regulated.

The clean-up takes place weekly. The riffle-poles are worn out and require replacement in a month. The gold is 861 to 863 fine. It travels 50 to 60 ft. down the sluice-boxes. Of these there are 10; each is 18 in. wide and 12 ft. long. The dump-box is 32 ft. long, 3 ft. wide, and 2 ft. deep. The total length of gold-saving apparatus is 152 ft. About 350 oz. are obtained as the result of a week's work.

The largest operation by drifting and thawing in the Fairbanks district was on No. 8 Below Discovery on Esther creek, where Clarence J. Berry and J. H. Hamil are conducting systematic work. To Mr. Hamil I owe the opportunity of seeing this interesting mine. (See Fig. 5.) It is entered by two shafts, placed at an equal distance from the dump-box, which is at the head of the sluices that extract the gold from the gravel. A block of ground 640 ft. long and 400 ft. wide, is divided into four parts by the

central position of the dump-box and the sinking of shafts midway between this centre and the extremities of the ground to be attacked. This is shown in the sketch (Fig. 5). At a distance of 40 ft. on each side of each shaft, a stub-drift is made; and at intervals of 50 ft. similar stubs are dug, allowing just room enough for a car. The profitable portion of the creek-bottom has a width of 400 ft., therefore the main drift has 200 ft. of ground on each side. The claim is located across the creek, so that it covers 660 ft. lengthwise and 1320 ft. across. This is unusual; ordinarily the longer measurement is up and down the creek. A cross-drift is run from the main drift along the end-line for a distance of 150 ft. each way and then stoping is begun, widening for 50 ft. more to the pay (Fig. 6). Thus a triangular area, A B C, is worked out, extracting the gravel farthest from the main drift. Then if the roof caves, as is likely, the working face is lost, usually at D. Now the stub-drift at H comes into play. A new cross-drift is extended from G to the caved stope, cutting into it at E. Then the block E B G F is mined. This leaves a triangular area, F G H, next to the main gangway, serving to protect it until the next stub-drift, at K, is brought into action. Finally the remnant F G H is mined and the ground allowed to settle, as it will. As the mining proceeds, the overlying gravel caves up to the covering of muck. The roof cracks and breaks away slowly. A warning is given by the ripping noise. Short stulls are placed in dangerous places, so that the crackling of the timber may give warning to any men close-by.

In driving the main drift it is customary to use steam-points, but the trimming of the drift is effected with a Worthington pump, using a half-inch nozzle. Then a set of timber is erected and the track laid. Sills are spread for the first 40 ft. from the shaft; after that the posts are set in the bedrock itself. There is danger of loosening too much ground if steam-points are used too freely, especially in the roof. Moreover, the thaw due to a point spreads unevenly, hence the employment of a small nozzle.

Thawing is done with steam-points 10 ft. long. They thaw 2 to 4 ft. beyond the inner end and through a vertical height of 4½ to 5 ft. They are placed 2½ to 3 ft. apart. Therefore the average duty of a point is 170 cu. ft. or about 6 cu. yd. The gravel is shoveled into a low car. The distance from the track to the top of the car is 32 in. and the capacity of the car is 18 cu. ft. The car holds the contents of six wheelbarrows or one self-dumping bucket.

The shaft is 90 to 92 ft. deep. In sinking, 42 to 45 ft. of muck is first cut. Sometimes a seam of sand is intercalated. The bedrock is a soft schist. In places the schist is blocky and then the yield of gold is best, reaching into the crevices for a depth of 2 or 3 ft. When the schist is soft as mud, the returns are low. From 3 to 3½ ft. of bedrock is mined. Usually 6 to 8 inches would include all the gold, but the uniform removal of bedrock to the depth mentioned is required to keep the floor level, the surface of the bedrock being uneven. The gravel itself carries but little gold; the metal is practically all on, and in, the bedrock. Mr. Hamil informed me that

*Sometimes the 'points' are placed as much as 5 ft. apart.

the overlying 40 to 45 ft. of gravel contains fine colors of gold, but as it is rarely tested no accurate information is available. The width of the gold-bearing channel varies suddenly at different places along Esther creek. On the flat a quarter of a mile below No. 8 claim the 'streak', as the width of pay is termed, is 1000 ft. wide and yields 75 cents per square

Fig. 3.

foot of bedrock. It has been tested by shafts and cross-cuts. On No. 7 Below the pay was only 150 ft. wide at the upper end-line and 400 ft. at the lower end-line, 1000 ft. apart. On No. 8 the channel widens until the edges of it are unprofitable.

The sump at the bottom of the shaft is sunk 15 ft. into bedrock. No live water is found. The same

Fig. 4.

engine and engineer work the buckets from both shafts, the discharge of gravel being made alternately. The dump box tends to store the gravel so that it is not all washed down the sluice-boxes right away, and it seems proper to ask why it is not possible to arrange for the systematic feeding of the gravel into the washing apparatus. Near the north shaft I saw a dump in which four steam-points were at work thawing the gravel accumulated during the pre-

vious winter. This was on August 8. The steam was conducted in a half-inch pipe for 150 ft. without any covering and connected with 200 ft. of pipe wrapped with asbestos packing and canvas. The radiation of heat was visible in the vibrating air.

Fig. 5.

Slabs of ice and patches of snow lay uncovered at the foot of the dump, where shoveled the night previous. The water from the sluice-boxes is re-used.

Self-Dumping Bucket Discharging on the Apron Above Dump-Box.

It runs into a ditch and is pumped back into the dump-box. This water, used for saving gold, is thick with mud and no effort is made to settle the slime. These criticisms are made because this was the best-managed drift-mine that I saw in the North and the

Fig. 6.

skillful operators who are doing the work are well able to meet such friendly comment.

Before beginning extraction of gold by sluicing, the development and equipment of this mine cost \$35,000.

OIL MEASURES IN THE COALINGA DISTRICT.

Written for the MINING AND SCIENTIFIC PRESS
By WILLIAM FORSTNER.

The Coalinga district has within the last few years taken rank as a prominent oil producer in California. This district can be divided into two portions: the Coalinga field proper, and that portion of the district lying south of the Coalinga field, extending southward to the Antelope valley. These two portions are separated by a stretch of country lying between the Waltham and Jacalitos creeks, wherein considerable disturbances of the formations render it quite impossible that commercially valuable oil deposits will be found. The Coalinga field proper lies north of Waltham creek, and is actually developed and producing oil over a distance of 15 miles north and south, and over a width varying from 1 to 2 miles. The stretch of country south of the Jacalitos creek, to the Antelope valley, 32 miles long, will be herein referred to as the Kreyenhagen field. In this field development is in progress, and numerous investments have been made.

Until last fall the only publication treating of the geology of this region was: 'A Stratigraphic Study in the Mount Diablo Range of California,' by F. M. Anderson, Proceedings of the California Academy of Science, 3rd. series, Vol. II, No. 2. In this treatise nothing, however, was stated regarding the occurrence of oil. The U. S. Geological Survey has made an examination of this region, and in the fall of 1908 the results were published in *Bulletin* No. 357, 'Preliminary Report on the Coalinga Oil District', by Ralph Arnold and Robert Anderson.

In discussing the probabilities of finding commercially available oil deposits within the Kreyenhagen field this report expresses an unfavorable opinion. An opinion stated by such an authority must carry weight, and being unfavorable, would tend to discourage investment for the development of a region so condemned. After a careful study of this region I have come to the conclusion that this opinion is more unfavorable than is warranted by the conditions.

On the east slope of the Mount Diablo range we find strata belonging to all the series included between the Franciscan and the Quaternary. The Cretaceous, Eocene, and Miocene formations occur in disconnected bands or lenses, showing that the subsidence of various parts of the region, or their erosion during the periods of uplift, were not uniform. There are in the Coalinga district two belts of brown shale, weathering white or light-yellow, forming conspicuous features in its topography: one of these belts is of Eocene and the other of Middle Miocene age. These shales are believed to be the source from which the oil is derived, not only in this, but also in other fields in California. There is a marked difference between the distribution of these shales in the Coalinga field proper, north of Waltham creek, and in the Kreyenhagen field, south of Jacalitos creek. In the Coalinga field the Eocene shales are prominent, while the Miocene shales are absent, the Middle Miocene being represented in this part of the district by sands and clays (*Bull.* 357, pp. 36, 37).

In the Kreyenhagen field the Middle Miocene brown shales form a very prominent feature; their outcrop can be followed uninterrupted from the Jacalitos creek to the Antelope valley, a distance of 29 miles. They are underlaid from the Jacalitos to Little Tar canyon, in Sec. 35, T. 23-17. It must be noted that the canyon called Little Tar in the map of *Bull.* 357, is the Esperanza canyon, and that Little Tar canyon lies about half-way between Esperanza and Big Tar canyons, by the Lower Miocene Vaqueros formation. Farther south this is probably overlapped by the Middle Miocene, and does not show again at the surface until east of the Devils Den. The Eocene shales are found only in this field, underlying the Vaqueros, between the main fork of the Zapatos creek, Sulphur Spring canyon, and Little Tar canyon, and are not found at the surface north or south of this exposure.

In defining the possible oil territory in this field Arnold and Anderson have started with the premise that: "The shale in the upper part of the Tejón is thought to be the source of the petroleum found in the Coalinga district. * * * Petroleum has not been found in this district except in beds associated with the Tejón and where the Tejón is absent the beds of the other formations are dry" (p. 28). They base this statement on the following:

(1) That the oil in the Coalinga field, the only proved part of the district, is derived from the Eocene, and (2), that in the Kreyenhagen field the oil seepages are found in the Tejón sands or in the Vaqueros, and not in the sands overlying the Miocene shales. As to the first, it has already been shown that the Miocene shales are absent in this part of the district. And as to the second, west of the Miocene shales the formations are cut by deep gulches and exposed at considerable depth: at these points the seepages are found. On the east slope of the Miocene shales the inclination of the strata is less, the surface is to a great extent covered by debris, and the canyons cut only to the solid rock, but hardly into it. The absence of seepage may be due to topographic causes. In a large portion of the Kreyenhagen field the Miocene brown shales are overlaid by a wide belt of clay shales, which may locally have prevented the accumulation of oil in the overlying sands. There is a belt of oil sand east of, and in a general way parallel to, the Miocene brown shales, which can be followed from the Jacalitos to a point east of Dagany Gap. This is probably the sand to which Arnold and Anderson refer as "supposed oil sand outcrop" (p. 111). I have taken a number of samples of this sand, tested them with chloroform, and obtained the following results:

LOCATION.	Reaction.
North line of Sec. 4, T. 22-15, bed Jacalitos creek.	Slight.
Sec. 24, T. 22-15, bed Zapatos creek.	Good.
Sec. 28, T. 22-16, bed Canoas creek.	Slight.
SE. $\frac{1}{4}$ Sec. 16, T. 23-17.	Very slight.
SW. $\frac{1}{4}$ Sec. 15, T. 23-17.	Very good.
Same locality, farther south.	Very slight.
W. $\frac{1}{2}$ Sec. 23, T. 23-17.	None.
NW. $\frac{1}{4}$ Sec. 6, T. 23-17.	None.
NE. $\frac{1}{4}$ Sec. 17, T. 24-18, near road from Dudley to Lemoore.	None.

I have further taken a number of samples of the Miocene brown shales in the Kreyenhagen field, and for comparison two samples of the Eocene brown shale in Big Tar canyon, where an important seepage is found, and where two wells have proved the existence of oil. Besides testing these samples with chloroform I had a microscopical examination made of some of them by W. Harold Tomlinson of Germantown, Pennsylvania.

Eocene, have proved that it is oil-bearing, although, due to the steep dip of the strata, they have not been commercially remunerative.

The territory east of the Miocene shales has not yet been tested. Three wells are being drilled in that part of the Kreyenhagen field: the Golden Crest, in Sec. 12, T. 22-15; El Cerrito, in Sec. 14, T. 23-17; and Pluto, in Sec. 19, T. 25-19. The results will furnish data to decide whether the unconditional con-

LOCATION.	REACTION.	PETROGRAPHICAL ANALYSIS.
Eocene shale, Big Tar canyon, lower strata.	Slight.	Argillaceous; hydrated iron oxides and globules of bitumen.
Eocene shale, same location, upper strata.	Medium.	Argillaceous; glauconite casts; bitumen markings along lines of strata; bitumen globules.
*Miocene shale, Upper Jacalitos, near Devil's gorge.	Good.	
*Miocene shale, at West Fork, Zapatos creek.	Medium.	
*Miocene shale, Main Fork, Zapatos creek, upper strata.	Medium.	Argillaceous; glauconite casts; globules and lines of bitumen.
*Miocene shale, same location, lower strata.	Slight.	Argillaceous; glauconite casts; bitumen stainings along lines of strata.
Miocene shale, Big Tar canyon.	Slight.	Argillaceous shale.
Miocene shale, west of the Devil's Den Co. oil well.	None.	Clay base, diatom spicules and tests, glauconite.
Miocene shale, north of the Devil's Den Co. oil well.	None.	Silicious shale; diatoms.
Miocene shale, Pyramid hills, between Esperanza canyon and road from Dudley to Lemoore.	Slight.	Argillaceous; glauconite and bitumen.
Miocene shale, Pyramid hills, east rim, west of the Pluto oil well.	None.	Silicious, diatomaceous, shale; butumen stains along fractures; globules of bitumen.

*There are no Eocene shales underlying these four samples of Miocene shales; in the Devil's gorge the Vaqueros rests on the Cretaceous, and in the two gorges of the Zapatos no Eocene brown shale was found.

The above shows conclusively that a great similarity exists between the Eocene and the Miocene shales, which is also recognized by Arnold and Anderson (pp. 23, 38). It cannot be denied that both have been deposited under similar deep sea conditions, conditions favorable for the production of oil, as the minute marine organisms have probably been the main source of the oil. In other parts of California the origin of the petroleum is ascribed to formations of similar character, of different age than the Eocene, and all conditions point to the diatomaceous or foraminiferal nature of the deposits as the determining factor in the occurrence of oil, rather than to the age of the formations (ibid. pp. 28, 29). Mr. Tomlinson writes me that the glauconite, which occurs in most of the shale specimens, is usually supposed to possess an organic origin.

We have then here a belt of brown shale, showing in many places organic remains, overlaid by sands giving in places reactions for bitumen, and it must be noted that all my samples were taken from the surface. This shale-belt varies in width from 50 to 2000 ft., and I cannot see any reason for denying its oil-producing possibility. The argument for the underlying similar Eocene shales rests on the presence of oil seepages close to their border, and in the fact that several wells, drilled in former years in the

demnation of the Kreyenhagen field as a possible oil producer is correct or not. Until then opinion as to future possibilities of the territory must be speculative. In justice to Arnold and Anderson, it must be stated that *Bulletin* No. 357 is only a 'Preliminary Report' on the Coalinga district. A great amount of money is being expended in the development of this field.

Lead in alloys offers some difficulties in analysis. Elborne and Warren announce a process depending on the insolubility of $PbCl_2$ in alcohol, the chlorides of most other metals (Pb, Sb, Cu, Fe, Zn, etc.) being soluble. 1 gm. of the alloy in fine shavings is treated in the cold with 50 c.c. concentrated HCl , and a slow current of Cl passed through for 24 hours. Such a current of Cl may be generated by the action in the cold of concentrated HCl on lumps of pyrolusite. Occasional agitation of the flask containing the alloy may be necessary. With some refractory alloys an occasional heating may prove desirable. After solution has been effected, evaporate the solution in a small weighed porcelain dish over a water bath. Cool, then pour over it absolute alcohol, stir, and immediately pour off through a dry weighed filter-paper. Repeat three or four times. Finally dry the dish and filter at 100° for 3 hours and weigh $PbCl_2$.

CYANIDING SILVER ORE IN HONDURAS.

Written for the MINING AND SCIENTIFIC PRESS
By GEORGE E. DRISCOLL.

At San Juancito, Honduras, the New York & Honduras Rosario Mining Co. has recently changed the system of ore treatment from pan-amalgamation and concentration to an all-slime filter-press cyanide system, concentration and amalgamation being discontinued entirely. As the ore is of a kind that a few years ago would have been considered unsuitable for treatment by cyanide, and as the results have been successful, a description of the changes made in the reduction plant and in the process may be of interest.

The ore is dumped over grizzlies at the mine, the coarse going to a sorting floor. It is washed and the waste rejected. The large pieces are crushed to about one inch, dropping from the crushers into a bin. The crushed ore is loaded into tram-buckets for delivery to the mill. The wash-water carries a large amount of slime in suspension, and to recover it, lime is added, the water being then settled in vats. The capacity of the vats at the sorting plant is not sufficient completely to settle all the slime produced by washing the ore; the overflow carrying away an extremely fine and light material, amounting to about 2¼ tons per day of 12 hours. This is collected at the mill and is treated apart from the ore.

At the mill the tram-buckets empty into a hopper above the ore-bin, from which the ore is drawn into a car and is weighed before being emptied. The car employed holds about 1400 lb. From the bin the ore passes by inclined chutes into Challenge automatic feeders at the stamps.

The stamps are 50 in number and weigh 750 lb. each when newly shod. The drop is 6 inches, 100 to 102 times per minute. The mortars are of the double-discharge type, with screens of 30-mesh steel wire-cloth. The stamp-duty is 2 tons per stamp per day of 24 hours. The ore is crushed in cyanide solution. Under the former system of treatment the pulp from the batteries flowed to two sets of pointed boxes; the classified product being concentrated on 12 Wilfey tables, the coarse product from the first box passing over an amalgamated copper-plate. Lime is added to the pulp after leaving the batteries.

The overflow from the last boxes was formerly conveyed to two conical bottomed settling-boxes with bottom-discharge, which de-watered and thickened the pulp for concentration; the tailing from the slime concentrators was also elevated by a centrifugal pump and passed over 12 canvas tables. The tailing from the canvas and Wilfey tables was all conveyed to a 4-in. centrifugal pump and elevated to a launder which discharged into the pan settling-vats, the coarse sand being first separated and fed to two Smidt tube-mills. The sand from the tube-mills was re-concentrated, the material settling in the vats was treated by pan-amalgamation, and the slime overflowing from the settling-vats, amounting to 15 or 20 tons daily, was conveyed to the cyanide plant.

This treatment was costly and complicated, while

the best extraction obtainable was 86%. In the summer of 1907 the company decided to adopt the cyanide process exclusively, and a 60-leaf slime-filter was purchased from the Charles Butters Co. The cyanide plant was enlarged to treat the entire output from the mill. On March 8, construction being completed as far as possible, with the works in operation, the mill was hung up to permit the final work to be done. The mill was stopped only six days; except for stops for a few trifling changes of a mechanical nature, which were made after starting, the mill has run constantly since, and the process has been pronounced a success.

The ore is crushed through 30-mesh screen in cyanide solution, and flows in wooden launders to a 4-in. centrifugal pump which elevates the pulp to three conical classifiers. The coarse sand is delivered to two tube-mills; the slime overflowing from the cone goes to two circular wooden settling-vats with peripheral overflow. The clear solution overflows into a vat to which is connected a 3-in. centrifugal pump; as the solution accumulates, the pump is started and the solution is raised to the mill-tank, from which it flows by gravity to the batteries to be re-used. From the tube-mills the sand is returned to the cones for classification, the final product going to the cyanide plant. This consists of material of which 90% will pass a 200-mesh screen. About every hour the slime in the settling-vats is drawn off and discharged by gravity into a wooden launder, which conveys it to the cyanide plant. This consists of 7 circular wooden agitator-vats, and two receiving vats, into one of which the pulp from the mill flows. The approximate capacity of the agitator-vats is 50, and of the receiving-vats 90 tons each of dry slime. The pulp from the mill flows into one of the receiving-vats, cyanide being added as the tank is filling, so that when filled the solution will be brought up to 0.2% strength. From the receiving-vats the pulp is transferred to one of the treatment-vats, where it is agitated from 40 to 60 hours before going to the filter. While being agitated, aeration is accomplished by circulating the pulp with a 6-in. centrifugal pump one hour, twice a day.

Samples of the pulp and solution are taken from the agitator-vats twice daily. These are filtered, the solution titrated, and, if needed, cyanide is added by suspending a perforated tin can, filled with this salt, in the pulp.

The exceedingly fine slime from the washing of the ore proved to be difficult to handle and required a large space to settle it. Attempts were made to utilize pan tanks in the mill, but without success. The only available method was to settle the slime in stone tanks below the mill, where it was de-watered, partly sun-dried, and returned in wheelbarrows to the mill. There it receives a preliminary treatment by agitation in solution in pans and settlers before going to the cyanide plant with the mill slime.

The pulp from the agitator-vats is pumped to one of two filter-vats immediately above the filter-box, into which it flows by gravity. When the filter-leaves are covered, the vacuum pump is started and

clean solution is drawn out until a cake of the thickness of $\frac{3}{4}$ to 1 in. has formed on the filter-leaves. A valve on the suction pipe is then opened, reducing the vacuum to about 5 in., which is found sufficient to hold the cake on the leaves. The surplus pulp is pumped out of the filter-box, returned to the vat, and the filter-box is re-filled with barren solution. The valve is then closed and cake given 40 min. solution-wash, which is followed by a 20-minute water-wash, after which the vacuum-pump is stopped, water is admitted to the filter-leaves, the cake drops off, and is discharged through a 10-in. pipe from the bottom of the filter-box. The time required for handling a charge is about 2 hours, the charge varying from 12 to 18 tons. The filter is operated by one native workman per shift.

After being in use about 3 months, an incrustation of lime forms on the filter-leaves, rendering them almost impermeable. To remove this the leaves are immersed in a 2% solution of hydrochloric acid, experience here having demonstrated that an immersion of 1 hour in an acid solution of that strength is

pumped through a small 40-frame filter-press, formerly used for filtering slime. When the press is full it is opened, the precipitate shoveled into sheet-iron cars and run into a drying-furnace. The cars are usually left in the dryer over night, and a fire is kept burning until the moisture has been reduced to 3% or less. On being removed from the dryer, the precipitate is spread on a cement floor. The entire lot is then passed over $\frac{1}{8}$ -in. mesh screen, after which it is weighed into lots not exceeding 770 lb. The different lots are carefully sampled and put into oiled canvas sacks, which are boxed and shipped to New York.

The plant produces about 4 tons of precipitate per month, a force of four laborers and one shift-boss being required to attend to the zinc-boxes, cleaning-up, drying, sacking, and boxing of precipitate. The solution entering the zinc-boxes contains an average of 14 oz. silver and 0.12 oz. gold. The out-going solution contains merely a trace of gold and seldom exceeds 0.08 oz. silver.

General View of San Jacinto, Honduras.

sufficient to entirely remove the lime, and will leave the canvas soft and clean. On being removed from the acid bath the leaves should be washed thoroughly until the acid is entirely displaced; otherwise the canvas will be quickly destroyed. It was found also that leakages in the leaves first occurred under the wooden ribs, and it has been found beneficial to sew a 4-in. strip of canvas under the ribs, this reinforcement adding indefinitely to the time a leaf may be used before undergoing repairs.

Precipitation is accomplished by means of zinc shavings, cut on the premises, six compartment boxes being employed. The precipitation from the solution may be regarded as perfect. The zinc in the head box is packed and replenished from the next box daily, the zinc being moved up, and new zinc added to the lower box. The boxes are cleaned out every three or four days, depending upon the richness of the ore treated. The precipitate and the solution from the boxes flow in launders to the sump-vat, into which they are washed through a 40 mesh screen. At intervals the agitator in the vat is set in motion, the pump is started, and the precipitate and solution

San Jacinto. Mill of New York & Honduras Rosario Mining Co. in Middle Distance.

Sodium cyanide of 127% strength is used exclusively. After the plant had been in operation a few weeks, potassium cyanide of 98% strength was tried, but the results were so unfavorable, in extraction and precipitation, that the use of it was discontinued. A two days' trial sufficed to show the superiority of the stronger sodium cyanide.

In the six months ending October 31, 1908, the plant treated 14,529 tons of ore of an average content of 40.05 oz. silver and 0.467 oz. gold. The tailing averaged 3.43 oz. silver and 0.019 oz. gold. The difference between the actual and theoretical extraction during this period was less than 1%. The cost of material, including zinc, cyanide, lead-acetate, hydrochloric acid, and lime, was \$5.21, or, at the present rate of exchange, slightly less than \$2 gold per ton. The chief item of expense was cyanide, the large amount consumed per ton of ore treated (almost 8 lb.) being due principally to four causes: moisture in the ore and slime, amounting at times to over 30%, which decreases the strength of the solution; to cyanide consumed in dissolving the precious metals; to the presence of cyanicides in the ore, the most active

of which are antimony and copper; and lastly, to loss in precipitation. This last amounts to approximately half a pound of cyanide per ton of solution passing through the zinc-boxes.

As the treatment-costs at present closely approximate the costs when pan-amalgamation and concentration were employed, the advantage of using the cyanide process lies chiefly in the lower labor-cost and in the higher extraction. As the material this plant is treating is a hard quartz, containing—in addition to the gold and silver—lead, copper, iron, and antimony, the results attained should aid in a revision of the opinions held by many writers, that silver ores are not readily amenable to treatment by cyanidation.

Tellurium determination has been subjected to close study by Leuker and Hornberger, whose results are given in detail in the *Journal of the American Chemical Society*. A brief review is given of the different methods proposed. Gutbier's method with hydrazine gave good results but requires slow addition of the reagent, taking too much time. NaHSO_3 requires a 24 hr. standing in a warm place, the solution being warm when mixed. A freshly prepared material for the reagent is necessary. SO_2 is also effective if the acidity of the (HCl) solution be fully 10% and the solutions kept hot. Twenty-four hours standing is necessary. By means of a combination of SO_2 and hydrazine, complete separation can be effected in a much shorter time. The Te as TeO_2 or as tellurate in HCl with approximately 10% free acid, is heated to boiling, and 15 c.c. of a saturated solution of SO_2 added, then 10 c.c. of a 15% solution of hydrazine hydrochloride, and again 25 c.c. of saturated SO_2 solution. Boiling is continued until the precipitated Te settles readily. This should not require over 5 minutes. Wash on a Gooch filter until all Cl is removed, then with alcohol, dry at 105° and weigh.

Cold-blast pig-iron, which is still made in Staffordshire, England, is chemically purer than hot-blast, partly because ores of good quality, containing but little phosphorus, are used to feed the furnaces. The cold-blast furnace, moreover, works at a lower temperature than the modern blast-furnace, and smaller percentages of silver, manganese, and other substances are reduced with the iron. The pig costs more to produce by cold-blast, but it brings a higher price, as it yields better castings for such purposes as the manufacture of chilled and grained rolls, hydraulic presses, or where great strength and closeness of grain are of importance. Cold-blast charcoal pig-iron is the purest and toughest made.

Anhydrite occurs in the Cactus mine at Newhouse, southern Utah. The mineral accompanies the chalcopryrite of that copper mine as a primary gangue mineral and is associated with tourmaline and a small amount of calcite and siderite. The hydration of the anhydrite results, of course, in the formation of gypsum, which mineral is abundantly found throughout the mine.

The Prospector.

G. B. U., Stanton, Arizona.—No. 1, epidotized metamorphic sediment—probably an arenaceous shale originally; No. 2, granite pegmatite; No. 3, pegmatitic granite; No. 4, ferruginous quartzite; No. 5, silicious shale.

C. E. S., Sweetwater, Nevada.—No. 1, dense aggregate of quartz with crystal-lined cavities (more probably vein quartz than quartzite but no certain determination is possible except in the field or on larger, more definite specimens); No. 2, quartz; No. 3, azurite or linarite in quantity too scanty for definite proof; No. 4, weathered pyritized quartzite; No. 5, hematite; No. 6, weathered andesitic lava.

H. L. S., Mexico D. F.—No. 1, pyroxene-amphibole plagioclase rock of porphyritic texture—hence a diorite or gabbro-porphyry; No. 2, gray-green garnets with calcite; No. 3, quartzite with development of garnet and epidote; No. 4, epidote and chalcedony with limonite and manganese oxide; No. 5, a lava with pellucid plagioclase and brilliant hornblende phenocrysts with a small amount of quartz set in a felsitic groundmass—hence, probably, a basic rhyolite; No. 6, biotite granite; No. 7, marble or crystalline limestone; No. 8, pyrite in altered granite; No. 9, porous quartz with limonite; No. 10, quartz-calcite-garnet rock with pyrite; No. 11, metamorphosed granite or granite-porphyry; No. 12, garnet in porous metamorphic rock; No. 13, crushed granite; No. 14, green garnets and calcite with chalcopryrite and hematite; No. 15, amphibole granite with pyrite; No. 16, weathered and metamorphosed granite; No. 17, basalt; No. 18, contact phase of granite with development of green garnet and pyrite; No. 19, impure limestone; No. 20, quartzite; No. 21, coal—probably bituminous because lighter in weight than anthracite but harder to ignite than many bituminous coals; No. 22, carbonaceous shale.

ELMORE VACUUM PLANT.

Written for the MINING AND SCIENTIFIC PRESS
By an Occasional Contributor.

The Elmore 'vacuum' plant for separating metallic particles and sulphides from gangue is tolerably well known to mining engineers and metallurgists, who are naturally watching it with close interest to see how it works in practice. The largest installation yet erected is at the Zinc Corporation's works at Broken Hill, New South Wales, where dumps of zinc tailing are being treated. The plant has been running for about a year and its capacity and possi-

The bulk of the material thus far treated has an approximate assay as follows:

Zinc	20%
Lead	5.75%
Silver	8 oz. per ton of 2240 lb.

The remainder is mostly heavy gangue of rhodonite and garnet, which cannot be separated by ordinary water concentration.

The concentrate obtained from the vacuum plant averages:

Zinc	43%
Lead	11%
Silver	17 oz. per ton.

The treatment on the Wilfley tables produces a

Removing a Dump of Zinc Tailing.

bilities definitely gauged, so some account of its performance will be of interest. The accompanying flow-sheet shows the operations to which the material is subjected. The material is first sized and such part as requires further comminution goes through a series of wet-grinding pans, so that everything shall pass through a 30-mesh screen. The pulp is divided into 16 parts and is distributed through 16 units of Elmore plant, each consisting of a cone-settler for thickening the pulp to the right consistence, a mixer for incorporating with it the oil and the acid, and a vacuum separating chamber. The concentrates obtained from these separators meet together again and are passed through de-oiling ovens, in which the oil is removed. To obtain more saleable products the concentrate is then passed over Wilfley tables and some of the lead separated. In this way separate zinc and lead products are obtained.

zinc concentrate and a lead concentrate assaying as follows:

Zinc Concentrate.		Lead Concentrate.	
Zinc	46.5%	Lead	58%
Lead	7.25%	Zinc	15%
Silver	16 oz. per ton.	Silver	39 oz. per ton.

The actual recovery by the Elmore plant is approximately 90% of the zinc, 73% of the lead, and 85% of the silver. Naturally some of the loss is due to the fact that the sulphides have been partly oxidized. There is also a slight loss on the Wilfleys, but it is not more than about 3%. The sulphuric acid used in the plant is manufactured on the spot and is of the usual commercial quality and the consumption varies from 10 to 20 lb. per ton of the material treated. The oil employed is Texas fuel oil and the consumption varies from 6 to 8 lb. per ton. When the plant was installed it was assumed that the capacity would be 500 tons per 24 hr. or about 30 tons for each unit.

As time went on the daily capacity has been considerably increased and each unit regularly deals with from 40 to 45 tons per day. The amount of labor required is small, for it is only necessary to have one man on each of the three floors to look after the separators, the mixers, and the discharge respectively.

The average costs as given by the Zinc Corporation are:

	s.	d.
Grinding	1	3.96
Elmore plant	2	4.00
Drying and de-oiling.....	1	3.64
Willeys		7.48
Total	5	7.08

In these costs are included: labor and salaries, general supplies, oil, sulphuric acid, power, water, fuel for de-oiling, repairs and maintenance, sampling and assaying, and sundries.

Up to the end of 1907 the plant has treated 150,000 tons and produced 57,000 tons of zinc concentrate and 3000 tons of lead concentrate. It is estimated that a profit is being made of 11s. per ton of material treated. The final figures cannot yet be obtained for several reasons, one being the nature of a contract for the sale of the products.

The latest information issued by the Zinc Corporation deals with the results obtained during January. The material treated was 16,560 tons, and the yield was 4845 tons of zinc concentrate and 410 tons of lead concentrate. The estimated contents of the zinc concentrate were 2717 tons of zinc, 397 tons of lead, and 90,597 oz. silver, and of the lead concentrate 229 tons of lead and 15,990 oz. silver. The estimated income from the products and also of sulphuric acid was £17,415, taking spelter at £20 per ton. The total expenditure, including treatment, management, and royalties, was £7707. The cost of material treated was £4140, so that the net profit for the month was £5568. It should be noted that the lead product is disposed of locally, and that the zinc concentrate is sold in Europe.

A method for determining lead in ores is thus stated by A. H. Low: Treat 0.5 gm. of the ore in the usual manner with acids, finally obtaining a mixture of PbSO₄ and insoluble portions of the ore on a 9-cm. filter. Dissolve the PbSO₄ through the filter by means of NaC₂H₃O₂ solution containing some free acetic acid, running the solution back into the flask in which the ore was originally treated. Add 10 c.c. of a 5% solution of K₂Cr₂O₇, boil to granulate the precipitate, filter, and wash but once. Now spread the filter-paper flat, and rinse all the precipitate from it into a beaker, with a hot solution of H₂C₂O₄ (1 vol. cold saturated solution to 3 vol. water). Heat nearly to boiling, add alcohol and boil to reduce CrO₃. Filter and wash thoroughly with cold water. Put the filter with the precipitate in a flask with 120 c.c. water and 5 c.c. H₂SO₄. Heat and titrate with standard permanganate. Theoretically, the oxalic (H₂C₂O₄, 2H₂O) value of the permanganate multiplied by 1.642 should equal Pb. In practice the factor 1.669 is more nearly correct.

BLAST-FURNACE TUYERE.

Written for the MINING AND SCIENTIFIC PRESS
By L. S. AUSTIN.

The Traylor Engineering Co. advertises a novel blast-furnace tuyere which strongly recalls one designed by the writer in the year 1900, a section of which is shown herewith. The upper end of the four-inch blow-pipe was connected to the bustle-pipe by a swing joint made of two 4-in. 45° ells. Connection was made between the blow-pipe and tuyere by a cast-iron sleeve having a ball and socket, or spherical joint, and the two parts were held together by a link. There was a turned sliding joint between the

sleeve and pipe, and leakage was mostly prevented by so-called air packing grooves turned on the sleeve as shown. It was expected that when the tuyeres were pulled, the link would be thrown off, the sleeve slid up, and the pipe allowed to hang vertically from the bustle pipe. No exact adjustment between the bustle-pipe and the tuyere was needed. For the peep-hole a plug and cap with a sight-hole was provided. A liberal slag-escape was arranged, which would be either closed with a plug of wood or with cotton waste. It was calculated that in the event of the tuyere being slagged, the sight-plug and the sleeve could be taken out and the tuyere in many cases cleaned. The tuyere was flanged and was secured to the jacket by studs, as shown in the transverse section. The design is not patented.

Resistance of surfaces moving through the air, according to experiments recently carried out by Albert Frank, and published in the 'Zeitschrift des Vereines deutscher Ingenieure', when the surface is perpendicular to the direction through which it is moved is 236 times that of the same surface moving through the air when it is parallel with the direction of motion. Thus the resistance offered to the motion of a thin plate normal to the direction of motion is 118 times that of a plate of the same area cutting through the air in a direction parallel to the motion, resistance in this case being offered by both sides of the plate.

MINE-TRACK SWITCH.

Written for the MINING AND SCIENTIFIC PRESS
By R. H. TOLL.

The device described herewith is so simple that I am constrained to apologize for publishing it, my justification being the hope that there may be other mine superintendents who had not thought of exactly this form of switch-tongue and to whom it may prove useful. The nearest approach which I have

Fig. 1. Mine-Track Switch.

seen to it was at the Congress mine, in Arizona, a number of years ago, where they welded a solid iron block to the butt of the rail, drilled a bolt-hole vertically through this, and countersunk the hole, at a cost of over \$2 per switch for extra material and labor.

The switch here described may be made in a few minutes by anyone with a cold-chisel and a drill, exclusive of the pointing, which is best done at the mill but may be done quickly at any forge. Cut out one to two inches of the leg of the rail about six inches from the butt, drill a $\frac{5}{16}$ -in. hole through the lower

flange, and secure it in position by a 60d. or an 80d. wire-nail driven into a tie. It may be necessary to put the spike in the hole in the rail and drive by striking the rail on top. Fig. 2 shows the hole cut in the leg of the rail, the drill-hole in the flange, and the method of trimming the end. Fig. 1 shows the switch in position on a straight track, dotted lines indicating the position on the curve.

It is well to place flat bars of iron on the ties under the switch-tongue to facilitate it sliding; also, to drive a track-spike inside each stationary rail in such position that the head of the spike will tend to hold the point of the switch against the rail and require a slight lift to release it. This form of switch may be used satisfactorily even on sharp curves. Mine-car wheels are so wide that a bend of two or three inches may be made in the switch-tongue, if necessary, without danger of derailing cars.

THREE-LEGGED TRESTLE.

Written for the MINING AND SCIENTIFIC PRESS
By MATT. W. ALDERSON.

The usual form of trestle or saw-stool employed by a carpenter has four legs. When used around a mine in framing timbers and in work of like character,

Handy Trestle.

it is not easy to make it stand solidly without leveling the ground with pick and shovel. This is not always convenient, especially where the ground is rocky or frozen. A preferable form of trestle is one with three legs, as shown in the accompanying illustration. It accommodates itself to inequalities in the surface and stands as solidly as a four-legged

Fig. 2. Switch-Tongue.

trestle under the best conditions. The mine carpenter should have a level place on which to do his work if possible, but sometimes circumstances will not justify this expenditure of time. A trestle of the kind here shown is more handy even in the shop than one with four legs. A board or timber may be sawed off close to the end with the single support without interference, and it facilitates the work of hewing.

Pyridine produces no precipitate in Mn (-ous) salts, but when added in slight excess will throw down $\text{Fe}_2(\text{OH})_6$ entirely free from manganese.

TABLE FOR CONVERSION OF METRES TO FEET.

The following table, prepared by Lee Fraser, will be found of assistance in the conversion of metres to feet. The two examples submitted will show the method of operation.

1. Required the equivalent in feet of 780.344 metres.	
Metres.	Feet.
780.000	2559.0474
0.340	1.1155
0.004	0.0131

zine, and tin so recovered in this country. To distinguish them from the so-called primary metals, which have been produced directly from ore, these metals are called secondary. A part of these secondary metals is sold as raw metal, but a large amount is turned out as alloys, such as brasses, bronzes, bab-bitt, and type metal. The following table gives the results obtained:

PRODUCTION OF SECONDARY METALS.		Approximate
	Short tons.	value.
Secondary copper as raw metal		
and in alloys	30,240	\$11,188,800
Secondary lead	9,990

Production of lead in the United States in 1907, according to the United States Geological Survey, reached a total of 365,166 short tons, or 33.3% of the lead production of the world. The production of Spain was 18.7% of the total, that of Germany 14.5, and of Australia about 9.7%. The following tabular statement gives the general items regarding domestic and world production and consumption :

LEAD STATISTICS IN 1907.		Short Tons.
Production of refined lead in the United States....	414,189	
Production of desilvered lead in the United States..	314,241	
Production of soft lead in the United States.....	129,607	
Production of antimonial lead in the United States.	9,910	
Total production of lead in the United States from domestic ores	365,166	
Production of secondary lead in the United States..	25,498	
Excess of exports of refined lead over imports.....	37,748	
Consumption of lead in the United States (disregarding stocks)	386,351	
World production (approximate).....	1,095,064	
World consumption (approximate).....	1,083,556	
United States percentage of world production.....	33.3	
United States percentage of world consumption....	35.6	
World rank of United States in production of lead..	First	
World rank of United States in consumption of lead	First	

Economy in the use and recovery or reclamation of metal products often wasted is of great importance. The extent to which old metals are recovered and re-used in the United States has been heretofore a matter of conjecture. A similar lack of information has existed as to the extent to which economy in the use of metals is practised by their recovery from skimmings, drosses, by-products, and the like. For 1907 the United States Geological Survey made a systematic attempt to ascertain the amount of copper, lead,

Llamas.

Analysis of llama dung, which is used as fuel in the high plateau of western South America, shows :

	%.
Moisture	0.5
Volatile matter	86.5
Fixed carbon	0.8
Ash	12.2
<hr/>	
Calorific power	100.0
Specific gravity—powder.....	2950 (Berthier)
Specific gravity—lump.....	0.30
	0.26

Average price per ton in Peru is 6.5 soles, equivalent to \$3.25 U. S. currency.

When determining zinc in zinc-dust by the volume of H evolved in treating with acid, it has been found that the use of rubber connections in the apparatus must be avoided, otherwise the results are too low. The phenomenon seems to be due to diffusion.

MINING AND METALLURGICAL PATENTS.

BALL GRINDING-MILL.—No. 910,761. Charles E. Wyman, Pekin, Indiana.

In a ball mill, an interior winding drum, a revoluble casing, an exterior grinding drum comprising an annular die immediately attached to said casing at the top thereof, another annular die rotatable with but slidable longitudinally of said casing held beneath the first-mentioned die, means to adjust the pressure between the first mentioned die and the interior drum comprising a bolt extending through said interior drum, a collar provided with arms held upon said bolt at the upper end thereof, rollers mounted upon said arms and adapted to bear against said first-mentioned die, a handled nut mounted on said bolt above said collar, and a spring held between said nut and collar, and separate means to adjust the pressure between the exterior die and the exterior drum, comprising a plurality of bolts attached to said casing, yokes carried on said bolts, nuts mounted on said bolts above said yokes, and springs between said nuts and said yokes, said yokes being rigidly attached to the said die.

HAND-POWER DRILL.—No. 911,755. Leroy S. Pfouts, Canton, Ohio.

In a drill of the class described, a base supported in proper elevation, slidable members carried thereby, a drill head bearing carried by said sliding plates and a drill head located therein, and a drill carried by the head, the drill head provided with a worm gear wheel, a worm adapted to actuate the worm gear wheel and drill head, a reciprocating hammer head, means for reciprocating the hammer head, and means for holding the hammer head out of action and means for rotating the drill head and drill independent of the reciprocating movement of the hammer-head, substantially as and for the purpose specified.

ART OF TREATING ORES.—No. 912,485. Robert McKnight, Pittsburg, Pennsylvania.

The art of treating thorium ores which consists in treating the ore with an alkaline chloride and heating the resulting mixture until volatile and soluble chlorides of the thorium have been formed, condensing what is volatilized and treating the residue with an aqueous liquid, substantially as described.

PROCESS OF MAKING CYANIDE BRIQUETTES.—No. 912,538. Julius Bueb, Dessau, Germany.

A process of making cyanide briquettes consisting in forming cyanide crystals into briquettes and subsequently

heating the briquettes in a vacuum to a degree sufficient only to drive off the water and not sufficient to decompose the cyanide.

MILLING AND LIKE MACHINE.—No. 911,841. Georg Reyher, Berlin, Germany.

An attachment for universal milling and like machines for converting said machine into an automatic machine consisting of a casing or support having means for detachably connecting it with the reciprocating table of the milling machine, a driving member and driving connections supported thereon for giving a forward and backward movement to the table, and driving connections also carried by said detachable support for giving a step by step movement to the dividing head of the milling or like machine, the driving connections first mentioned comprising gearing for giving the forward movement to the table, gearing for giving a backward movement thereto, a clutch with means for operating it to throw into action either one gearing or the other, means for controlling said clutch from the movement of the work table, and the driving connection last mentioned comprising gearing and a clutch operated at a certain point to cause said gearing to move the dividing head with means for throwing said clutch out of operation automatically when the dividing head is adjusted, substantially as described.

BORING-MACHINE.—No. 911,639. Moses L. Andrew, Delhi, Ohio.

A boring machine comprising a horizontal rail provided with a central horizontal slot and with a slot above and below the central one, a splined shaft journaled to the rear of the central slot of the rail, a block fitted to slide in the central slot, a bracket lying against the face of the rail and provided with vertical slots across the upper and lower slots of the rail bolts engaging the vertical slots of the bracket and the upper and lower slots of the rail, a vertically movable boring spindle journaled in the front of the bracket, a shaft journaled in said block, bevel gearing connecting the front end of the shaft with the boring spindle, bevel gearing connecting the rear end of the shaft with the splined shaft, and a work-table disposed below the boring spindle, combined substantially as set forth.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

AIDS TO SHIPPERS is the title of an unusually valuable compendium of information compiled and published by Oelrichs & Co., 5 Greenwich St., New York. It gives instructions concerning packing and marking goods for ocean shipment, consular invoices, customs entry, drawbacks, insurance, lighterage, and the like. The tables are equally useful, comprising conversion of metric into United States weights and measures, and values of foreign coins in great detail. A large array of foreign weights and measures is gathered into the most elaborate table of the kind we have ever seen. While going to such lengths it seems unfortunate that it was not made even more thorough. For example, the Spanish and Spanish American *almud* is entirely omitted; the *manzana* is given only for such small countries as Costa Rica, Nicaragua, and Salvador; *ganado* and *caballeria* are not included, and other lack of judgment is displayed in this collection. But it is nevertheless a remarkable little book, and will be of great use to all persons going to foreign parts.

HYDRAULIC TABLES: THE ELEMENTS OF GAGINGS AND THE FRICTION OF WATER FLOWING IN PIPES, AQUEDUCTS, SEWERS, AND OTHER CONDUITS. By Gardner S. Williams and Allen Hazen. 2d. ed., 8vo., pp. 104. New York: John Wiley & Sons, 1909. Price \$1.50.

These famous tables are presented with careful revision, and may be assumed to have eliminated errors as thoroughly as may be possible. A further explanation of the Hazen & Williams formula, as to the last term, is given; also additional new matter appears in relation to submerged weirs. Other expansions have been made in the text relative to weirs, this feature of the book being one that will meet with cordial welcome by all engineers. The work is a necessary adjunct to the equipment of any man having to deal with hydraulic problems.

TEMPERATURE ENTROPY DIAGRAM. By Charles W. Berry. 2d. ed., revised and enlarged, 8vo., pp. 290. New York: John Wiley & Sons, 1908. Price \$1.25.

This admirable treatise has been of great service to all students of thermodynamics, and to engineers dealing with the application of steam and gas and hot air in power-development where high efficiency is sought. The book is intended as an introduction to the advanced study of thermodynamics. The discussion is illustrated by diagrams. The chapter on the flow of fluids has been re-written and treats at length of the irreversible process. One chapter deals with mixtures of gases and vapors, and another describes the principle and use of F. Mollier's total energy-entropy diagram.

TEXT-BOOK OF PETROLOGY. By F. H. Hatch. 8vo., pp. 404, ill. London: Swan Sonnenschein & Co. New York: The Macmillan Co.

This is the fifth edition of a little book that has proved most useful; it contains a summary of the modern theories of rock-origin, a description of the rock-forming minerals, and a synopsis of the chief types of igneous rocks, as illustrated by their distribution in the British Isles. The author describes the mineral constituents and internal structure of igneous rocks, their mode of occurrence at the surface, and their origin beneath the exterior of the earth. The book has won well deserved success.

MINERAL RESOURCES OF THE UNITED STATES for the calendar year 1907. In two volumes: Part 1, metallic products; Part 2, non-metallic products. Published by the U. S. Geological Survey.

El Noticiero has reached its fourth number, and continues the promise of usefulness given in the preceding issues. The copy before us contains an important article on the

concession for a national bank of issue for the Republic of Honduras, granted to A. J. Moisant. Difficulties over the recent decision of the Court of Cartago lend peculiar interest to financial arrangements in Central America.

REPORT OF THE DIRECTOR OF THE MINT UPON THE PRODUCTION OF THE PRECIOUS METALS IN THE UNITED STATES. Issued by the Treasury Department, Washington, D. C.

THE INTERPRETATION OF TOPOGRAPHIC MAPS. By Rollin D. Salisbury and Wallace W. Atwood. Professional Paper No. 60 of the United States Geological Survey.

ECONOMIC GEOLOGY OF THE GEORGETOWN QUADRANGLE, COLORADO. By Sydney H. Ball. Professional Paper No. 63 of the United States Geological Survey.

Commercial Paragraphs.

THE BYRON JACKSON IRON WORKS, West Berkeley, Cal., has recently received an order for a number of 5 and 6 in. turbine pumps to be used on a sugar plantation near Honolulu. This order is a duplicate of one filled by the same company six months ago.

BETTLES, MATHEZ & Co., of Salt Lake City, have a metallurgical and chemical laboratory for custom assaying and making tests for the guidance of those who contemplate erecting ore reduction plants. The principal members of the firm are A. J. Bettles, manager of mills for the Newhouse interests, and Augusté Mathez, mining engineer. A. F. Bardwell, formerly of Aspen, Colorado, is manager.

THE NATIONAL WOOD PIPE Co., Los Angeles, has recently made the following sales: To the Southern Pacific railway, 6000 ft. of 6-in. machine banded redwood pipe for use at Santa Barbara; to the Ash Meadows Water Co., 20,000 ft. of 6-in. pipe for use at Rhyolite, Nevada; and to the Grand Canyon Electric Light & Power Co., 15,000 ft. of 4, 6, and 8-in. pipe for use at Williams, Arizona. The company has just opened a general sales office at 210 Wells Fargo Bdg., Portland, Oregon.

THE POWER & MINING MACHINERY Co. of Cudahy, Wis., reports the following sales of mining machinery: Through the International Mach. & Eng. Co., Mexico City: Cia. Minera de Tenamache, one 10-stamp mill with crushers and 5 by 18 ft. tube-mill; Cia. Minera la Victoria y Topada, one 10-stamp mill complete with 5 by 18 ft. tube-mill; Cia. Minera San Antonio, one 10-stamp mill with 5 by 14 ft. tube-mill. Through the San Francisco office: Harris Mining & Milling Co. of Nevada, 10-stamp mill equipment; Seoul Mining Co. of Korea, one 5 by 22 ft. tube-mill.

Catalogues Received.

THE BLAKE & KNOWLES STEAM PUMP WORKS, New York, are distributing four new Bulletins, No. BK 825, 826, 827, and 828, covering vertical triplex power pumps, deep well pumps, and ammonia pumps.

THE DU BOIS IRON WORKS, Du Bois, Pa., has just published its 1909 catalogue descriptive of Du Bois gas engines and producer gas plants. Anyone interested in this rapidly growing industry would do well to send for this catalogue.

THE KELLY FILTER PRESS Co., Salt Lake City, Utah, is distributing its 1909 catalogue which describes and illustrates in detail the Kelly filter press. It should be in the hands of anyone interested in filtration.

THE HARRISON-WALKER REFRACTORIES Co., Pittsburg, Pa., has just published a handsome catalogue bound in leather, with gilt edges. That fact in itself does not mean much, but when one realizes that the contents of the book are well worth the elaborate binding, then the reason becomes apparent. Every person interested in the use of fire brick or other refractory materials should have a copy. An interesting feature is 60 pages devoted to detail drawings of different furnaces, boiler settings, and the like. In addition to the complete dimensions of the various shaped brick, there is included a number of pages of useful information.

EDITORIAL.

OUR London correspondent makes mention of the highly satisfactory report presented at the recent annual meeting of the Exploration Company. Many of our readers will share our pleasure in being informed of the successful operations of this pioneer among the houses of issue responsible for important mining enterprises. We note also, with interest, that Mr. R. T. Bayliss, the chairman, announced the formation of a new company financed by his associates with the purpose of carrying out a systematic scheme of exploration in Mexico. The undertaking is to have a capital of £250,000, and Mr. Robert M. Raymond, the present manager of the El Oro and the Mexico mines, at El Oro, is to be general manager. The enterprise will start under the best auspices and should prove both successful and useful.

IN his speech, as retiring president of the Chamber of Mines of the Transvaal, Mr. Lionel Phillips spoke most cheerfully concerning the local mining industry. Although local in a sense, the operations around Johannesburg are of world-wide importance. Since 1884 the Transvaal has produced £227,084,385—pounds, not dollars. In 1908 the tonnage treated was increased by 2,670,000, and the dividends distributed by £1,659,700. Up to date the gold mines of the Transvaal have paid £55,041,587 in dividends. At the present time the earnings of the producing companies yield a return of 8.79 per cent on the market valuation of the shares. Working costs, in 1908, were reduced 2s. 9d. per ton, and thereby the ore reserves of the 67 productive mines have been increased by 5,400,000 tons, or 9 per cent on the previous estimate. These are large figures, but they are in keeping with a mining district that yields one third of the gold being produced in the world.

IT IS presumable that the production of zinc ore in Mexico for shipment to the United States would have increased under the stimulus of high prices for spelter, had such continued, and no one would have been concerned to thwart the Mexican producer while all went merrily at home; but when depression came, and one mine after another in the zinc regions of the Mississippi Valley was forced to close, the increase of 25 per cent in importations of ore from Mexico in one year challenges attention. The average zinc-content in the Missouri ores is about 60 per cent; in the Mexican it is 40. The Mexican ore costs the smelter about \$16 per ton. As one ton of the American ore is equivalent in metallic content to one and a half of the imported ore, for equal amounts of recoverable spelter the cost of the Mexican would be \$24, as opposed to a cost of production at the Missouri mines of nearly \$38. It is proposed that in the interest of the zinc miner a tariff of 11½

cents per pound be imposed on the metal in the imported ore, which would enable the American to command a price of \$42 per ton. That would allow him a profit of \$4, which is reasonable. Certainly it is not reasonable to protect the smelting companies by a tariff on spelter, which sustains an industry that benefits comparatively few, while the mines which afford work to many are left without assistance. If the public be asked to tax itself for one or the other, it should answer by taxing itself for both or for neither.

PLATINUM at the present time comes mainly from the placer mines of the Iss and Tura rivers, tributaries of the Tiumen, on the eastern slope of the Urals. The mines are owned by a French syndicate, which thereby controls the platinum market, but the neighboring Russian proprietors, notably Shuvaloff, have contracted to sell their output at a fixed figure to the French syndicate. For purposes not understood the price of the metal has been lowered to \$24 per ounce as against \$39 not long ago; the reason being either that the consumption has not kept pace with the supply, which has been cornered, or that the producers are afraid of competition on the expiration of existing contracts in the Ural, as well as from Colombia.

COLLAPSE has overtaken the independent smelter at Ponderay in Idaho. Disaster was inevitable from the beginning. A small plant, dependent solely on smelting with a lead base, and having no means for treating matte, had no chance for survival. Complaints of discrimination by the railroads are freely made, but without having in hand specific allegations on this point, we may observe that the regulations approved by the Interstate Commerce Commission would of necessity operate against Ponderay. The Montana Mine Owners' Association would have done better to have erected a new plant at Helena or Tacoma. They might at least, in that event, have actually competed with, or, in other circumstances, have sold out to the 'enemy'. As it is, they have been paralyzed by a 'chill' that bespeaks poorer business judgment than metallurgical ability.

WHEN the brothers Cowles produced aluminum alloys direct from ores in the electric furnace at Lockport, New York, and the pure metal was made electrolytically by Charles S. Bradley, the arrival of the aluminum age was confidently announced. That was nearly twenty years ago. Today the revolutionary effect of introducing a great new factor into the metal industries of the world is on the verge of realization. The claims of inventive genius have been paid off, the utilization of aluminum on a grand scale having been delayed until the obligation was satisfied. With an unfettered opportunity this metal will draw the attention of metallurgists henceforward equally with iron and copper. An interesting article on some characteristics of aluminum will be found elsewhere in this issue. It should be pointed out that the alloys of aluminum offer a remarkable field, and will probably expand rather than reduce the consumption of copper.

A BILL is now before the Russian Duma to introduce into Russia a complete system of workmen's insurance. The plan as proposed has been drafted by the Ministry of Commerce and Industry and in general follows the German system. It will probably soon become a law and will be a boon to foreigners operating mines or other industrial enterprises in Russia, removing vexatious liabilities and at the same time raising the efficiency of labor. Special insurance companies are to be formed under the joint control of the Ministry of Commerce and Industry, the local administration, and representatives of the mine or factory owners. Funds will come from premiums paid by workmen, taxes on employers, fines, and voluntary contributions. In case of accident totally disabling a workman, he receives an amount equivalent to two-thirds of his regular wages until able to resume work or given a pension for permanent disability. If he is able to return to work, but with decreased earning power, a proportionate allowance is made to him. In case of death provision is made for his widow and children; benefits are paid in case of illness as well as accident; women and children workers, as well as men, participate in the insurance. The insurance companies will also give attention to the improvement of workmen's conditions, sanitation, hospitals, safety-devices, and so forth. What a lot of damage suits, expensive litigation, and needless suffering this enlightened law would save if adopted in the United States!

Deep Metal Mining.

As our readers are aware, the deepest gold mine is the Victoria Quartz at Bendigo, in Australia; this mine has a vertical shaft that has been sunk to 4300 feet and a winze that is 225 feet deeper, making the total depth 4525 feet. In these deepest workings a saddle-reef has been cut, but it does not carry pay-ore, in fact, the Victoria Quartz Company has asked the Government of Victoria for a grant of £10,000, and the Minister of Mines has replied that he would provide the money if the company would agree to sink another 1000 feet. In California, the main shaft of the North Star mine at Grass Valley is down 5400 feet on the vein, which has a dip of 28°, so that the maximum vertical depth is only 2086 feet. At the bottom the vein is larger and shows more gouge than on the upper levels; in consequence, more waste is mixed with the ore, reducing the average yield to \$12 per ton for a width of 6 feet, as against the 18 inches of \$18 ore that was extracted from the upper workings. No defined ore-shoots exist, the mine is becoming less wet, but the prospects of profitable exploitation continue undiminished with increase of depth. The neighboring Empire mine has an incline shaft that is down 3500 feet on the vein but only 1570 feet vertically below the surface. This mine is said to be in a highly productive condition. The Kennedy, on the Mother Lode, in Amador county, is one of the famous mines of California. The maximum depth attained is 3254 feet, with stoping in progress from 2000 to 3000 feet, and an excellent showing at the bottom. The shaft is now being sunk. Speaking in a general way, on the Mother Lode the rich ore found

at surface reached to about 300 feet; between that depth and 700 feet there was, in many cases, an impoverishment, which was succeeded at 1000 feet with another zone of profitable ore, extending to 1700 feet; then the lode became poor again until about 2500 feet, at which depth a few mines obtained another lease of life. On the Comstock the deepest mining now in progress is on the 2300-ft. level of the Ophir, which is 2552 feet below the Gould & Curry outcrop. It will be remembered that the greatest depth attained on the Comstock was in a winze in the Mexican mine, which, before the flooding of the workings in 1884, reached down to 3308 feet, or 3554 feet below the Gould & Curry outcrop. On the Rand the shaft of the Cinderella Deep is down to 4200 feet and that of the Jupiter to 4230 feet. Before long Johannesburg will have many deep mines. In Brazil the Morro Velho shaft of the St. John del Rey has reached a depth of 4264 feet. But the deepest metal mines are still in the Lake Superior copper region. There the Red Jacket shaft of the Calumet & Hecla mine is 4920 feet vertical; while the Tamarack has two shafts over 5000 feet deep, namely, No. 5, which is 5180 feet, and No. 3, which is 5230 feet vertical. These Tamarack shafts were sunk to extract ore from the copper lode first exploited in the Calumet & Hecla, and they cut a lode having a dip of 38° at a vertical depth of 4660 feet. By attaining a depth of one mile underground and by showing with what ease operations are conducted at that great depth, these Lake Superior mines have demonstrated that man is likely to be able to penetrate at least as profoundly into the earth as the ore persists.

Protection of Investors.

We have given our space freely to the discussion of the question how best to protect mining investors, believing that it would tend to the formation of a healthy public opinion on the subject. In this, as in many other matters of public interest, there is more danger in drifting than in perverse steering. Even if no panacea for the ills of the speculating portion of the community may have been discovered, it is well to note that no one has dared to express opposition to the effort to cure the ills that afflict the business of mining. No one, for instance, ventures to say in print that shareholders ought to be kept in the dark as to the doings at the mine, or that the directors are entitled to pervert their position as trustees into advantageous gambling, or that the manager is warranted in doctoring his reports according to the needs of his stock speculations. Men may do these things, but we are at least so far on the road to reform that none dare advocate such doings openly. On the contrary, public opinion is becoming clarified; that is one of the functions of serious journalism; that also is one of the functions of professional associations such as the Mining and Metallurgical Society of America. Laws are useless without the momentum of public opinion; that is why so many new statutes are still-born and so many old enactments have become dead letters. In America, particularly, the protection of mine investors is a ques-

tion that needs ventilating because the misuse of money in fraudulent or foolish schemes is one of the heavy taxes paid by the mining industry. England has the Companies Acts to protect the investor, but better than any Act of Parliament is the public opinion gradually developed in London by force of example and by compulsion of criticism. Even an English company is compelled by law only to furnish a balance sheet, and it is obvious that this constitutes a small part of the information required by anyone wishing to understand the condition of a company's affairs. English mining companies do more; they have learned to treat their shareholders fairly and to give information frankly. Why? Because, in the first place, those in control of meritorious mining enterprises desired to win the confidence of the conservative type of investor; they had something to show and were willing to show it, thus compelling others by force of example to follow their lead in the hope of winning a similar reputation for honorable dealing. As soon as it became the characteristic of successful mining companies to give full and prompt information to their shareholders, it also became advisable for doubtful enterprises to imitate such practices. It became fashionable; which means that the public expected it. When the Exploration Company, John Taylor & Sons, Bewick, Moreing & Company, the Consolidated Mines Selection Company, and similar houses of issue, showed some respect for the intelligence and property rights of shareholders, it became incumbent upon the Whitaker Wrights, the Hooleys, and the Bottomleys, to go through the motions, at least, of giving information, in order to avoid public censure. Thus an excellent custom was created. And at a time, eight or nine years ago, when the custom suffered from lax observance, a group of mining engineers in London forced the hands of the company-promoters and stock-jobbers by furnishing criteria for the valuation of mines and explaining the methods of appraisal. That again put the company-managers on their mettle and led to the publication of real information, so that today the minority shareholder is fairly well protected. If he consider himself ill treated, he may attend the annual meeting, and raise a rumpus. If properly done, he will win support; if improperly, he will waste time. This feature of company-management has humorous aspects, and brings the proceedings occasionally to the verge of burlesque. Directors find it well to permit recalcitrant shareholders plenty of chance to air their grievances, recognizing that nothing will alienate support so readily as even an appearance of lack of fair play. In consequence, lawyers and others seeking notoriety will occasionally make themselves a nuisance; yet on the whole this publicity is an excellent safety-valve for discontent, and an admirable corrective of directorial superciliousness. We should have more of it in America; in England a director is made to feel, by law and by public opinion, that he is a trustee, not a privileged insider with first access to information and a prior chance to buy and sell stock advantageously. A sense of honor curbing selfishness would improve the management of mining companies.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

FRANCIS L. BOSQUI is at New York.
JAMES A. GILMOUR is at Leon, Nicaragua.
C. W. GEDDES is at Calabacillas, Chihuahua.
GEORGE E. FARISH is here from Mexico City.
FRED L. MORRIS has returned from New York.
HOWARD D. SMITH was at Oroville during the week.
EDWARD SIMPSON is returning from Tacoma to Dawson.
R. R. MOORE, of Garfield, Utah, is temporarily in Mexico.
W. H. STAYER, of Freeport, Illinois, is now at Hemet, California.

JAMES W. ABBOTT of Pioche, Nevada, was at Salt Lake recently.

CHARLES T. MINER has returned from Sinaloa, Mexico, to Salt Lake City.

FREDERICK G. FARISH, of Denver, was in San Francisco during the week.

GEORGE WHELOCK, of New York, is examining mines in Nevada and Idaho.

O. B. PERRY was at Oroville this week, and is now on his way back to New York.

EMERSON GEE is in Oaxaca, Mexico, but will return to Los Angeles early in April.

OSCAR S. MARKS, lately at Winnemucca, Nevada, is temporarily in San Francisco.

R. A. KINZIE has returned to San Francisco from a visit to Goldfield and Ely, Nevada.

BEN S. REVETT, of Breckenridge, Colorado, was in San Francisco during the past week.

H. C. SANDIFER, who is operating at Seven Troughs, Nevada, was in San Francisco lately.

ALTON L. DICKERMAN has returned to Boston from Northern Ontario and will proceed shortly to Mexico.

CURTIS L. KNIGHT, former superintendent of the Valcalde mine, Silver Peak, Nevada, is at Salt Lake.

VICTOR C. HEIKES, statistician of the U. S. Geological Survey, stationed at Salt Lake City, was at Butte recently.

J. M. NICOL has returned from a visit to Trinity county.

F. R. CARPENTER and ARTHUR HOWE CARPENTER, of Denver, were recently in Nevada and Utah.

FRANK ELMORE, having put into successful operation the 12-unit vacuum concentration plant at the Sulitjelma copper mine in Norway, has left for Trondhjem.

CHARLES W. WRIGHT, of the U. S. Geological Survey, has returned to Washington from Sardinia, Italy, where he made an examination of the Pertusola lead and zinc mines.

The Pacific Coast section of the Mining and Metallurgical Society of America met in regular session on March 13 at the Key Route Inn, Oakland. The following members were present: S. B. Christy, A. C. Lawson, F. W. Bradley, R. A. Kinzie, George W. Starr, Charles Butters, C. C. Derby, E. A. Hersam, T. A. Rickard, M. L. Requa, and W. H. Shockley. Also the following guests: Ross E. Browne, Charles Hoffmann, George Hoffmann, E. H. Garthwaite, and E. B. Durham. The next meeting will be late in April.

Obituary.

HENRY BAUSCH, who died at Atlanta, Georgia, recently, will be gratefully remembered by microscopists for his many original contributions to the advancement of that branch of science. He was a good example of the man who brings high technical qualifications into alliance with commercial enterprise. He was vice-president of the Bausch & Lomb Optical Co., of Rochester, N. Y., and was fifty years of age at the time of his death.

General Mining News.

ARIZONA.

The copper production in Arizona last month, as reported by interests which yield nearly 90% of the output, was 26,500,000 lb. The Copper Queen led with 9,150,000, the Calumet & Arizona and Superior & Pittsburg made 4,000,000, and Senator Clark's United Verde mines produced almost 3,000,000 lb. Arizona in 1908 produced almost 295,000,000 lb. of copper. Twenty-five years ago Arizona was almost at the bottom of the copper-producing camps of the West. Arizona's copper production has more than doubled in 10 years. In 1908 Arizona produced more copper than any other State, making 33,000,000 lb. more than its nearest rival, the State of Montana.

GILA COUNTY.

Work on the extension of the Gila Valley, Globe & Northern railway to Miami has been begun and will be completed as rapidly as possible. This will give a great stimulus to the activity of the mining district of Miami flat.

CALIFORNIA.

NEVADA COUNTY.

E. H. Wilson has secured a bond on the Oustomah mine, and has already taken charge of the property. A new wire cable has been ordered and the shaft is to be sunk deeper, while the 10-stamp mill will be started presently.—Mark B. Kerr, of the Pittsburg-Gold Flat-Potosi mines, has completed a contract with the Bay Counties Power Co. to furnish electric power for the mines of which he is manager. In the past the Pittsburg was operated by water-power. The machinery at the mine is being overhauled and placed in good condition for work. Men are making headway in cleaning out and repairing the old drain adit.

SAN BERNARDINO COUNTY.

The Montana lease, in the Big Chief tunnel, has struck a bonanza, from the richest portion of which assays up to \$2000 per ton have been obtained. The high-grade streak, varying in thickness from 3 to 8 in., is one of the richest deposits discovered in the Hart district. In the same drift, about three weeks ago, Charles Hammer found another bunch of rich ore, but in a few feet it pinched out, owing to a fault occurring at that point. Foster & McCluskey, the owners of the Jumbo, have been finding ore on the 100-ft. level of their mine which surpasses anything they had previously opened. This vein is about 4 ft. wide and shows an abundance of free gold. The east cross-cut has exposed the Jumbo vein as being 25 ft. wide, all of which is of sufficient grade for milling purposes. William L. Foster has issued his report on the Big Chief and Long Shot claims at Hart. In the east side adit about 300 ft. of work have been done, while in that on the west side more than 700 ft. of progress have been made. Three veins have thus far been cut, all of which are of milling grade, with some streaks of quite rich ore. A special meeting of the stockholders will be held in Phoenix, Arizona, on March 30, to effect the merging of the Hart Consolidated and Big Chief estates. As soon as this is accomplished active work on the Consolidated will be begun, and a 40-hp. hoist installed to sink a shaft.—Twelve miles west of Hart a discovery of uranium ore has been made by W. J. Murphy; it occurs in calcium phosphate, and an analysis by W. B. Meade, of Barnwell, shows 11% of uranium oxide. The pure oxide is quoted at \$3.50 per pound.

TRINITY COUNTY.

(Special Correspondence). The Union Hill mine near Weaverville are running successfully and doing good work,

using three Marysville giants. C. G. Goodyear is manager and H. E. Crowell secretary.—The Trinity Gold Milling Co., with headquarters at Kansas City, is operating the old Baudrey mines near Weaverville. They have about 15 miles of ditch line. An open flume built of steel, by the Risdon Iron Works, leads down to their pipe-line. This flume is set at a grade of 30°, is 1000 ft. long, 3 ft. wide at the top and 18 in. at the bottom, and 4 ft. deep. It discharges into a large penstock from which the pipe-line starts. A steel flume was installed, as it was found that on a steep grade a wooden flume wore out too rapidly. The pipe-line is over 2000 ft. long and is equipped with four branches at the lower end, two of which go to the mine, one to the small electric lighting and hoisting equipment, and the other to the sawmill. Operations at the mine are carried on by means of three large giants, No. 5, 6, and 8 respectively. The banks are about 100 ft. high and the sluices are set at a grade of about 8 inches in 12 ft. I understand that one very good clean-up has been made and that prospects look bright for a successful run this season. W. V. Whipple is general manager.—The Trinity River Mining Co. has practically completed its tunnel through the big bend and is now contemplating the installation of a power-plant to develop pressure water by pumping, for the purpose of operating in the river channel, which will be exposed as soon as the water has been turned through the tunnel. John M. Nicol, hydraulic engineer of the Joshua

The Sierras as Seen in San Bernardino County.

Hendy Iron Works, has recently been on the property for several days, making plans and estimates for the complete equipment. The project seems feasible, and prospects are good for an early installation.—The Boomer mine near Denny, on the New river, has been pushing development work all through the winter and they expect at an early date to cut the vein in the new cross-cut which is being driven. R. A. Skinner is lessee and manager.

TUOLUMNE COUNTY.

J. L. Tonkin and M. E. Sanford have brought suit against W. H. Remington and J. D. Barber to recover possession of the Patricia, Marie, and Sanford mining claims, in Wet gulch, near Columbia. In addition to the payment of the purchase price of \$8000, the defendants were to sink a shaft at a designated point in the Patricia 100 ft. deep, unwater the old shaft, construct a hoist, and to install a small mill. The plaintiffs claim that the machinery placed on the mines was of poor quality and that the shafts and drain tunnel, by reason of poor work and neglect, caved in, causing damage to the amount of \$3500.

COLORADO.

CHATEAU COUNTY.

Fred Kuenzel hopes to blow in four of his new process furnaces at Buena Vista early in May, each having a capacity of 50 tons per day. The steam and electric plants are being installed, and a spur track from the D. & R. G.

railroad has been laid to connect with the ore-bins of the smelter.

CLEAR CREEK COUNTY.

(Special Correspondence).—Records have been filed with the county clerk whereby the Silver Creek Mining Co. and Kate Bullis, deed to the Alice Development Co. the Alice group of mines situated in the Alice and Yankee districts. The consideration is said to have been \$300,000, a cash payment of \$88,000 having already been made. The territory embraces over 1100 acres of mineral-bearing ground. About a year ago A. H. Roller and W. L. Shaffer, both of Idaho Springs, secured an option on the Alice mine, and tested for the best method to extract the gold. A 5-stamp mill was erected, equipped with an electro-chemical process, and demonstration was made that the entire vein matter could be handled at a profit. It is now intended to construct a reduction plant with a capacity of 150 tons per day.—The Fall River Power & Light Co., with a capitalization of \$100,000, has been incorporated to construct reservoirs for the storage of water on upper Fall river, where electricity is to be generated to be sold throughout the lower end of the county. A big group of claims is controlled, and work is to be put under way at an early date. A. H. Ristedt, of Idaho Springs, is the moving spirit in the enterprise.—Development is progressing in the Seven-Thirty and Dives-Pelican mines, most of which is being done through the Burleigh adit workings. The ore now being broken in the stopes of the Phillips vein is sent to the Pelican mill for concentration. This mill is running one shift only, but next week a night shift will also be put to work. The aerial tramways running to the Pelican dump are doing excellent work, about 200 tons of ore being delivered daily. The bins have a capacity of 1500 tons, and now that they are practically full, a heavy tonnage of concentrates will be marketed from this time on.

Georgetown, March 13.

LAKE COUNTY.

Dudley M. Gray, manager of the Dinero mine, is making good progress in connecting the adit of the mine with the old shaft, which is now full of water. Three raises are being put up from the adit level, and are drawing much of the water-flow from above, besides developing abundant ore which assays about 75 oz. silver per ton. When within a reasonable distance of the Dinero shaft, a drill-hole will be run from one of the raises to obviate the danger of a rush of water.—The Ontario tunnel near Twin Lakes is producing good ore from a 3-ft. vein which was discovered last fall, and the owners are now contemplating the erection of a mill.

OURAY COUNTY.

Among the transfers recently recorded in Ouray is one by Thomas F. Walsh to John W. Benson of an eighth interest in the Goodluck, Goodluck Extension, Tarmagan, and Groundhog, and a 92% interest in the Pocahontas lode mining claims, all in Sneffels district and situated near the Camp Bird mine.

TELLER COUNTY.

John H. Nicholls has been appointed superintendent of the El Paso Consolidated Gold Mining Co. at Cripple Creek. He has formerly been general manager for the Prince Albert Mining Co. in the same district.—The Portland Gold Mining Co. made an exceptionally good showing in February. The properties are now operating in a way that indicates the certainty that the \$2,000,000 mark for annual yield will be attained this current year. The total production last year was 94,311 tons, of the gross value of \$1,835,000, the average value per ton being \$19.45.—Frank O. Ganson has opened up a flat vein in the Mary McKinney mine which is now exposed for a length of 18 ft., and is from 3 to 6 ft. thick. Part of this is shipping ore worth 2 oz. gold per ton, and the remainder when sorted will be a good grade of milling ore.

IDAHO.

BONNER COUNTY.

H. D. McLeod, of Cleveland, is at Sandpoint on the shores of Lake Pend d'Oreille, superintending the construction of

the Midas galena mill from his own designs.—John Mo-cine, secretary and treasurer of the Idaho Smelting & Refining Co., has been appointed receiver of the Panhandle smelter at Ponderay, owned by the Greenough Bros. and the Montana Mine-owners' Association. Shippers have been advised to stop consignments of ore, and it is given out by Thomas L. Greenough, general director of the company, that 1000 tons of ore on the ground will be treated under the management of the receiver. The Idaho Smelting & Refining Co. was organized six months ago to take over the holdings of the old Panhandle Smelting Co. and assumed its indebtedness. This now amounts to about \$200,000.

CUSTER COUNTY.

The Golden Sunbeam Mining Co., operating on Jordan creek, 4 miles from Custer, has free-milling gold ore in a vein that strikes through rhyolite. Ore averaging \$25 per ton is being run through a crusher and a Monadnock mill fitted with amalgamating plates. It is reported that a recovery of \$1600 in gold was made in 10 days in February. C. E. Gable is in charge.

OWYHEE COUNTY.

The Overlook Mining & Development Co., of which J. W. McCaw is president, has acquired two full quartz claims in the gold-bearing region 70 miles south of Boise, to develop the vein, said to be 20 ft. wide. Neil Campbell, of Walla Walla, is manager. The company has owned three claims on the lode, two carrying timber, and a mill-site since 1907, and it is intended to erect a 15-stamp mill there this coming summer.

SHOSHONE COUNTY.

George A. Cunningham, general manager of the Empire Mining & Development Co., has entered into a contract with Felix LeMarinel and D. C. Nicholson to run a cross-cut 1000 ft. long in the mine on Revenue gulch, two miles north of Wallace. The cross-cut is expected to strike the vein when 800 ft. of advance have been made, at a depth of 280 ft. The vein is on what is known as the Osborn Fault, as defined by the United States Geological Survey.

MICHIGAN.

The Superior is resuming rock shipments to the Atlantic mill. The south drift on the seventh level shows a remarkable richness. This drift is largely responsible for the high mineral returns from the past mill runs, which averaged 37 lb. copper per ton during the month of February.—The Michigan is sinking shaft A below the 16th level. It is now over 2000 ft. from the surface. From the 12th to the 15th level the ground shows some slight enrichment. The 16th level shows the lode narrow, but with greater enrichment. A large tonnage is blocked out in the old Minnesota branch, which may soon be stoped.—Victoria's drift west on the 22nd level is getting into exceptionally good copper ground, about 400 ft. from the shaft. The company is operating a single shift, owing to the scarcity of water. There is small likelihood of the force being increased to any extent for another 60 days.

MONTANA.

SILVER BOW COUNTY.

H. V. Winchell, consulting geologist of the Amalgamated Copper Co., and former chief geologist of the Great Northern railway, has made an examination of the East Butte mines and declares their condition excellent and the prospects promising.—The Anaconda Co. is still engaged in re-timbering the Belmont shaft from the 1000-ft. level to the surface, and work will not be completed for several months.—It is understood that new capital has been interested in the properties of the Amazon-Butte Co., which owns a valuable group of claims south of the Pittsburg & Montana properties. It is expected that operations will be resumed within the next six weeks. The work was suspended more than a year ago, because of the financial depression. The Amazon-Butte Co. owns six claims, with a shaft 400 ft. deep.—On the Badger State the Amalga-

mated Copper Co. is enlarging the shaft from 2-compartment to 4-compartment, and the shaft is now down nearly 1200 ft. It is understood that it is the intention of the company to eventually use the Badger State on the north, and the Belmont on the south, as the two principal working shafts for all of the mines controlled by it. This will minimize the cost of hoisting and reduce the cost of mining materially.

NEVADA.

ESMERALDA COUNTY.

J. H. Mackenzie, of the Goldfield Consolidated, is giving up the management of that property, now that he has accomplished the construction of the new mill and has organized the development of the mines' orebodies. He will still retain general direction of the undertaking, leaving the execution thereof to his staff. Mackenzie is now turning his attention to the oil fields at Coalinga, in which he is interested together with Messrs. Wingfield, Nixon, Bradley, and Requa.—The new process of gold extraction from the concentrates by an acid process devised by J. W. Hutchinson, superintendent of the Consolidated mill, is doing good work. It is recovering a high proportion of the total content, and is also saving an immense amount of freight and smelting expense to the company.—A test run of about 100 tons of the ore now exposed at the Valcaldia mine, near Blair, controlled by Samuel Newhouse, will soon be made with a view of determining the efficiency of the plant; and if results are satisfactory the capacity will be increased to 150 tons at least per day.

HUMBOLDT COUNTY.

The Imlay Mining Co. has made arrangements for the construction of its mill at Imlay. The contract for both equipment and buildings has been given to the General Engineering Co. of Salt Lake.

LINCOLN COUNTY.

Some fine specimens of vanadate of lead taken from the property of the Noble Five Co., four miles east of Morgantown, are being displayed in Crescent.—A. J. Peak was the sole owner of the Silver Sphinx at Nob Hill prior to the present incorporation.—It is now called the Oxnard-Eldorado Mining Co., with a called-up capital of \$30,000. Present arrangements for development entail sinking the shaft 500 ft., installing a gasoline hoist, and erecting new mine buildings.—It is said by officials of the Nevada Utah Co. that a large body of high-grade ore has been uncovered in the May Day mine, and has been proved down to the 800-ft. level.

NYE COUNTY.

The Tonopah Co. sent 3200 tons, the Belmont Co. 850, the Montana-Tonopah 781, the Midway 100, MacNamara 350, West End 135, and Jim Butler 200 tons to the mills, making a total shipment for the week of 5616 tons, with an estimated value of \$140,000.—The most notable development of the week at Pioneer has been a strike of rich ore in the 300-ft. level of the Mayflower mine. The new mill is handling ore of good quality. The ore is delivered from the mine to a Blake crusher set at 1½ in. The broken ore is passed to the 5 stamps crushing to 40 mesh, and thence to the amalgamating plates. The stamps weigh 1000 lb., drop 100 times per minute, and were furnished by the Joshua Hendy company of San Francisco. The mill has a capacity of from 12 to 15 tons per day. It is estimated that sufficient ore is blocked out to keep the plant running for six months.—The Taylor Bullfrog Mines Co. is arranging to resume work at its properties in Gold gulch. A 10 hp. engine will be installed.

(Special Correspondence).—The Dronham lease on the Balloon Hill has opened up a 4-ft. body of good grade ore. The shaft is being sunk to the 150-ft. level.—The Royal Mines Co. has resumed work on its lease on the Royal-Tiger. The incline shaft will be sunk from the 440 to the 500-ft. level. John E. Pelton is general manager.—The Rawhide Mountain Leasing Co. has relinquished the Big Four lease on the Rawhide Consolidated. Lack of funds is the reason

given.—The Weiss mill is running through 50 tons of \$15 ore from the Mint lease. The Mint management has leased the Murray mill and in the future will treat most of its low-grade ore at this plant. The mill has a capacity of 30 tons per day.—The Gold Reef Co. has taken over the lease on the Grey Eagle Fraction and is pushing work on the tunnel. The life of the lease is three years.—The Mother Lode lease has uncovered a 4-ft. vein on the estate of the Rawhide Queen Co. The vein has been developed for about 80 ft.—The shaft at the Royal Regent is down 50 ft. and it is intended to install a hoist in the near future and sink the shaft deeper. The vein is apparently a continuation of the orebody opened up in the Walters' Boys lease on the Czar claim.—The Bradshaw lease is arranging to install a 25-hp. hoisting plant at its recently completed vertical shaft. This lease is making steady shipments of good ore.—San Francisco and Rawhide capitalists are promoting a new bank and plan to erect a large custom mill. The plans of the promoters are said to be practically completed.—The camp is very quiet, although considerable work is going on, most of this being performed by lessees. Between 60 and 70 hoists are in commission.

Rawhide, March 10.

WASHOE COUNTY.

An immense deposit of iron ore has been discovered in the Fort Sage range of mountains near the California-Nevada line, within about four miles of the Western Pacific railroad. Analyses of the ore show 68% iron, only 0.007% phosphorus and no sulphur. The deposit is in the shape of a dike 400 to 1000 ft. wide, and has been followed for a distance of five miles. With electric smelting of iron ores a demonstrated success, western Nevada may some day become an iron manufacturing district. The principal owners of the deposit are W. H. Paul, of Salt Lake City, John S. Phillips, and Orlando McNabb, Nevada mining men.

WHITE PINE COUNTY.

The Scott Mines Co., a Salt Lake corporation, is reported to be negotiating for the purchase of 363 acres of land, containing extensive deposits of iron ore, in the Ely district, owned by the Ely-Calumet Co., controlled by Tex Rickard, Al D. Meyers, and John K. Turner. It is said that the deal involves about \$500,000.

OREGON.

JACKSON COUNTY.

Abe Lamb, manager of the Ashland Peak mine, situated three miles south of Ashland, states that the adit, which is being driven on the vein by machine drills, is now in 250 ft. The vein is 7 to 9 ft. wide, stands vertical, and is well-defined between clean-cut walls. After the orebodies are well opened up a quartz mill will be installed at the mine.

UTAH.

JUAB COUNTY.

(Special Correspondence).—The shaft of the Gemini mine, at Eureka, has reached a depth of 1900 ft., the last 200 ft. being below water-level and in sulphide ore. The extensive workings above the 1700-ft. level were entirely in oxidized and carbonate ores, the silver found there being chloride, bromide, and iodide, associated with cerussite; while below water-level the silver occurs as stephanite, argentite, and combined with galena and gray copper, with some ruby silver. There is also, in these sulphide ores, an improvement in the percentage of copper over that found in oxidized ores. The sulphide ore is of excellent grade and the vein structure below water-level is the same as that above it. The Gemini is in the limestone and, while there are deeper mines in this formation in the Tintic district, it is the first to reach sulphide ore.

SALT LAKE COUNTY.

Connections have been made between the main shaft and the raise from the Mascotte tunnel, at the mine of the Ohio Copper Co. in Bingham canyon. The two workings came

together exactly, and has caused genuine satisfaction to Colin McIntosh, the manager. The complication and length of the survey was very considerable, and McIntosh says that much credit is due to Frank Goodman and John Berg, the two surveyors who laid out the work.

George and Jerry Peterson, brothers, who were entombed in St. Patrick's mine in Hughes canyon, at the lower end of Big Cottonwood, as a result of a cave-in of a tunnel of the mine, were rescued after fifty hours of heroic effort upon the part of the rescuers. The men were imprisoned about 300 feet from the mouth of the tunnel, and were threatened with death from three sides—starvation, suffocation, and drowning. Samuel Newhouse and several of the district managers were on the scene superintending the rescue of the men, who are now reported to be well on the way to recovery.

TOOELE COUNTY.

The mill of the Boston Sunshine at Mercur is nearly complete, and will be ready for its daily capacity of 200 tons per day within a couple of weeks. The process has been so designed as to obviate the necessity for roasting.

SOUTH DAKOTA.

LAWRENCE COUNTY.

(Special Correspondence).—A number of mines and mills will resume work this spring, some of which have lain idle for two or more years. The most important of these is the Branch Mint, with 120 stamps and a cyanide plant. It is situated at Galena, 12 miles east of Deadwood. James Harden is the manager.—A new mill will be started next month 5 miles east of Deadwood. This is the Golden Crest, with L. A. McCandless as superintendent.—The Lucky Strike Mining Co. is another in the same district that announces its readiness to start milling operations in a short time.—Among others making the same announcements are the Tinton tin mines, the Girtie tin mines, the Christopher Columbus, and the Echo Mining Company.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—Strikes of ore are reported from the Jennie mine, in the northern part of the county, and also from the Summit Mining Co.—At Republic the lessees of the Insurgent mine have prepared a carload for shipment, that assays about \$25 per ton.—The San Poil Republic Smelting Co. has been incorporated by R. W. Howard, W. B. Parker, R. J. Leonard, and others, of Spokane, Wash. It is reported that preparation for the installation of a smelter will begin about April 1. It is possible that a long-talked-of scheme to draw iron sulphide ore from Belcher district, 12 miles northeast of Republic, to flux with the Republic dry ores, may be carried into effect. The final articles of incorporation have not yet been filed.

Republic, March 13.

SPOKANE COUNTY.

Announcement is made that a tungsten refinery to cost \$25,000 will be erected in Spokane this year to treat the ores from the tungsten mines near Deer Park, Washington, and Murray, Idaho. The only tungsten refinery now at work in the United States is at Boulder, Colorado. There are four cars of tungsten ore on the dump at the Deer Park mine ready for shipment, and it is given out that this ore is worth \$800 per ton.

STEVENS COUNTY.

Alexander Sharp, manager of the First Thought Gold Mines, Ltd., is planning to build a cyanide mill on a site selected on the east side of the Kettle river, and considers the Park's process to be the most suitable for the treatment of the ore. He has reported that the ore can be treated on the spot for \$1.25 to \$1.50 per ton. No ore has been shipped by the company assaying less than \$20 per ton, and a big tonnage assaying between \$5 and \$20 has been piled up at the mine awaiting treatment. A new cable has been ordered to replace the old one in commission between the mine and the mill.—A gasoline hoist and full equipment have been purchased for the Copper Butte mine.—

Capt. L. Beecher has been organizing a company in Washington to acquire a number of mining claims in the Orient district and operate them under the same management.

CANADA.

BRITISH COLUMBIA.

A. J. McMillan, managing director, and W. A. Carlyle, consulting engineer of the LeRoi mine at Rossland, which closed a few days ago because of the lack of ore, are going to London, to confer with the directors as to future plans. The exploration work in the lower levels have not proved the extension of rich orebodies found toward the end of last year. As it is not economical to ship ore and carry on exploration work upon a small scale, it has been decided to suspend operations until arrangements can be made for carrying out development work in a more comprehensive way.—A 40-ft vein of good ore has been found on the ninth level of the War Eagle, and demonstrated to be over 400 ft. long. Assays give results between \$20 and \$100 per ton.—Strikes are also reported on the eleventh and twelfth levels of the Centre Star mine. This mine continues to produce about 3000 tons per week, and made a clear profit of \$30,000 during the month of February.

Work has been resumed by the Kootenay Development Syndicate on the Silver King mine near Nelson. Twenty-

Cobalt in Winter.

six men are employed at present and it is announced that the force will be increased this spring. Four machine-drills and a compressor are in operation. The mine was discovered by the Hall brothers in 1888, and was extensively developed by English capital. It was closed in 1902 and with the exception of some of the upper levels has not been worked until the present time. The Development Syndicate secured a lease on the property last summer, and preparations for the re-opening of the mine have progressed so well that now the eight upper levels are in shape to produce its copper and silver ores.

ONTARIO.

The shipments of a recent week at Cobalt amounted to 528 tons, of which La Rose, Nipissing, and the Crown Reserve each contributed over 100 tons. The others making up the total were the Right of Way, Trethewey, City of Cobalt, and Cobalt Central. The Kerr Lake Co. has found some good ore at a depth of 150 ft., in a vein 7 in. wide that extends out under the waters of the lake. The Temiskaming and Crown Reserve companies have both declared 6% quarterly dividends, and the latter has added an extra of 9%. Silver was first produced from this camp five years ago; yet in that time over \$20,000,000 worth of silver have been produced, and over \$11,000,000 have been paid out in dividends up to the beginning of 1909. This distribution of 56% of the entire production to shareholders should be a fitting object lesson to some of the other great mining camps of this continent.

MEXICO.

DURANGO.

Work is now well under way at the Libertad mine in the San Diego district, near Velardeña. These mines were idle for several years until recently. José Maria Correa, the former general manager, has been called from Naica to again take charge of this work. The Libertad mine is owned by wealthy Parral capitalists and adjoin the Montañesas mine, which has been shipping high-grade ore to the Torreon smelter.—Rhodesia is the name of a mining concession, 110 square miles in area, lying to the north of Guanacevi. A company has now been organized in London with a capitalization of £300,000 to exploit this concession. Some time ago 125 pertenencias were located, and in the last few months 300 more have been taken up. F. J. M. Rhodes is the manager on behalf of the London proprietors.

The American Zinc Extraction Co. has purchased the property of the Parral Milling Co., and has begun tearing down much of the plant in view of installing newer types of machinery. Tests have been made in Kansas City of the ore the company expects to treat, and the initial capacity of the new plant will be 100 tons daily. The representatives of the two companies who effected the deal are Rowe & Swain, for the American company, and José Botello, for the Mexican.—It is reported that the Montreal company which has supplied Pachuca and Guanajuato with electric power has made plans to do the same for the Parral district, by building a hydro-electric power-plant on the Rio Conchos.

FEDERAL DISTRICT,

The Mexican Mining and Metallurgical Institute met at the American Club, and adopted the official name of 'In-

View on Guanajuato.

stituto de Minas y Metallurgia.' Bernard MacDonald was elected president, and there were also present: A. Grothe, E. DuBois, W. H. Blackburn, E. P. Merrill, G. H. Garrey, George E. Farish, H. S. Denny, J. D. Helm, Kirby Thomas, Marion L. Thomas, J. Leslie Mennell, E. Ordoñez, Godfrey D. Doveton, Clive S. Newcomb, R. H. Anderson, J. C. Brennon, W. M. McNeely, H. Simpson, Victor M. Braschi, P. A. Babb, F. Narváez, H. A. Barker, J. B. Empson, E. Girault, J. W. Johnson, H. C. Enos, H. L. Lawrence, and Richard H. Chism. The next meeting will be on March 25.

GLAXO-MITCHELL

A vein, believed to be the continuation of the Nopal lode, is being opened by two drifts on the 300 ft. level of the Nueva Luz mine. The same vein also shows in the *socaron* at a higher level, and is there 5 ft. wide, carrying over 500 gm. silver per ton. The manager, M. Heinrich, is subordinating work on this vein in favor of active development on the Valenciana ore-shoot.

HDDM Co.

The Pachuca Mining Co has let a contract to John Hooper to sink the three compartments of the Edward VII shaft a depth of 200 metres, it being now about 98 metres deep. Crosscuts will be driven north and south to intersect the lodes known as Analcos and Remedios. The shaft is situated in a claim immediately to the

south of the La Blanca and Santa Gertrudis mines, and so the development in depth will be watched with interest. —The tunnel No. 3 of the Santa Ana mine at Pachuca is now in 1273 ft., and within a month will tap the intersection of the Santa Ana and Capula veins at a depth of 600 ft. This work will prove the extremities of the vein for a distance of 2500 ft. The work on this property is at present self-sustaining.

JALISCO.

James P. Harvey and H. L. Percy, of Los Angeles, are in the United States making arrangements for a concentrating plant with a daily capacity of 200 tons for the Magistral copper mines in the Ameca district. The Magistral mines were purchased last October for ₱100,000.—Marcus Daly and Ernest A. Wiltsee, of New York, have just made an inspection of the Cinco Minas in Hostotipaquillo. These mines, which are famous *antiguas*, were recently taken over by the Daly estate and a preliminary payment of ₱50,000 made. The balance due is ₱480,000, and it is probable that this amount will be paid immediately. The Daly interests plan a modern reduction plant at the mines, and a wagon-road to connect with the Southern Pacific extension.—The Lawson Development Co., of which Thomas W. Lawson of Boston is president, has resumed work on its custom mill on the San Geronimo *hacienda* in the Mascota district.

Part of Jalisco, Mexico.

The plant was nearing completion when all work was stopped more than a year ago. A deal is now on for the Mascota properties of the Santa Lucia Mining Co., a Philadelphia concern, in order to increase the available ore supplies.

SONORA.

News comes from Douglas that the Phelps-Dodge Co., which owns the Copper Queen and dozens of other mines and railroads in the territory, is to acquire the El Tigre gold mine, some 50 miles south of the international line at Douglas. This is possibly the only mine in the western country that was ever stolen bodily after it had become a producer. B. F. Graham and others sold the mine to Kansas City parties for \$650,000. Claiming default in payment on a technicality, they rushed an armed force into Mexico, took forcible possession of the property, and began to work it as their own. After a long and tiresome trial in the Courts, the Mexican Government restored the mine to the Kansas City owners, who are now about to sell the mine to the Phelps-Dodge Company.

W. G. McBride, of the Sonora Consolidated Mines Co., is making arrangements to work his property, which he asserts contains ore running 20% copper, 30 oz. silver, and \$4.50 gold. It is situated six miles from the Cabullona ranch and 16 miles south of Douglas.

Special Correspondence.

LONDON.

Exploration Co.—San Francisco del Oro.—Le Roi No. 2.—Ymir

The Exploration Co. and the chairman, R. T. Bayliss, are to be sincerely congratulated on the results obtained during 1908. A year ago it was necessary to refer to this company as being hard hit by misfortune, notably due to the collapse in copper and to the consequent depreciation of copper and other shares. Since then the debit balance has been wiped out and a considerable balance remains to credit. For the year 1908 a net profit of £59,979 has been made, out of which £37,500 has been distributed as dividend. In addition, the company has now cash resources to the extent of £2,255,974 and the investments stand at £492,528. Among the investments, Mexican gold mining shares stand for £56,000, South African shares £52,000, real estate in Johannesburg £97,000, and shares in copper companies £199,000. The copper companies include the Greene-Cananea, Butte Coalition, Nevada Consolidated, and the Otavi. An interesting announcement has been made to the effect that Mexican mining is to receive special attention in the future, and that a separate company is to be formed for the purpose of testing and developing properties in that country. The capital is to be £250,000, of which the whole will be subscribed by the Exploration Company.

One of the Mexican properties owned in London, the San Francisco del Oro, has up to the present time given its directors and shareholders a good deal of anxiety. The ore is a complex zinc-lead sulphide containing gold and silver. Owing to the scarcity of water, concentration presented difficulties, and rich shipping ore was relied upon for income. Many experiments were made with dry concentrators, but without success. Some months ago a fortunate discovery of water made during development operations, altered the aspect of the case. It was decided to try the system of concentration adopted at Broken Hill, and the matter was referred to W. E. Simpson, who has had special experience in that problem at the works of the Zinc Corporation. He is also known as a successful metallurgist at Lake View Consols and Oroya Brownhill in Kalgoorlie. His experiments showed that the Broken Hill practice was suitable for this ore, and that large proportions of lead and silver may be readily saved. The question of treating the zinc residue will be investigated later, on the spot. Mr. Simpson has been appointed general manager, and is leaving for the mine immediately. It is not expected that more than £5000 will be spent on re-modeling the plant, for there is already an excellent equipment, and the company has this amount in hand. At first the modified plant will have a capacity of 100 tons per day, and further expansions will be decided on when the duty of this unit has been ascertained. Apparently a troublesome problem has been solved which will lift the company from misfortune to success.

The prospects at the Le Roi No. 2 at the present time are better than during any period in the life of the company. It is now about five years since the present board took command and placed the management in the hands of Alexander Hill & Stewart. At first the outlook was far from bright, and the managers held out no large hopes. However, by careful and systematic examination, sufficient ore was found to keep the mine going and to yield profits. In the meantime prospecting with the diamond-drill has proved the existence of large bodies of good ore. Most of the ore extracted during the last few years has come from the 300 and 500-ft. levels, on the Hamilton vein. Diamond-drilling along the course of the vein has shown it to continue to the 700-ft. level, and the drillings give an average of over 2 oz. gold and 2.8% copper. Concurrently with this exploration, similar investigations have been made at the bottom of the mine from the 900-ft. level. At depths between 1200 ft. and 1300 ft. a vein has been struck, which is apparently a continuation of the Le Roi south vein, belonging to the adjoining company. It is figured that the vein is 7 ft. wide

and assays 1 oz. gold and 4¼% copper. In the adjoining mine the vein is being worked at the 1650-ft. level in good ore, so that the prospects at the Le Roi No. 2 are favorable. The main shaft is being re-timbered in part and preparations are being made for sinking below the 900-ft. level. To meet these expenses funds are being accumulated from revenue. The profit for the year 1908 was £53,053, of which £37,800 was distributed as dividend. The ore shipped amounted to 29,648 tons averaging a little below 1 oz. gold and 1½% copper, with a gross value of \$23.60 per ton. In addition 15,044 tons of low-grade ore were milled yielding 1129 tons of concentrate averaging 1 oz. gold and a trifle less than 1% copper, but it is an ore that does not concentrate well.

Exploration by diamond-drilling in British Columbia has become the basis of an enterprise determined upon by the directors of the Ymir Gold Mines, Ltd., to issue £20,000 new capital for the purpose of exploration by such means. For some time R. Gilman Brown has been studying the Ymir deposit, and has investigated both the old vein and new ground. The old vein yielded good returns in the earlier days, but it became erratic in depth, and its exact nature

Mexico Mines of El Oro.

is still not known. At a point 200 ft. below the surface, and 800 ft. from the old vein, a detached mass of high-grade ore was found. This mass is probably connected with another vein, according to indications, and it is chiefly with the object of finding this other vein that the additional capital is being raised. The Ymir is an excellent plant, consisting of 80 stamps, concentrators, and cyanide equipment, all driven by water-power. It is situated at the mouth of the adit, or 1000-ft. level. The risk of £20,000 in further exploration seems amply warranted.

DENVER, COLORADO.

Conservation Commission.—Vidler Tunnel.—Oil Prospects.—Cripple Creek.—San Louis Valley.

The Colorado conservation commission, composed of 36 prominent business and professional men, met in the Chamber of Commerce building, at Denver, on March 11. After effecting a permanent organization, committees were appointed to consider forestry, water, lands, minerals, natural history, and legislation. The commission will meet again on May 14 to hear the recommendation of the committees, and to take further action. It is to be hoped that this commission will bring to public notice some of the more noticeable wastes in mining, as well as in the industries which touch the more visible resources of the State. Probably in no other State are there more extensive coal beds lying so near the surface as in Colorado, and the waste in extraction in many districts is almost criminal. The trouble lies largely in adopting methods unsuited to the conditions. If the commission turn the attention of engineers and oper-

ators in this branch of mining to the art of saving as well as of getting, it will do a great service to the State.

There seem to be indications of an active season in the east Argentine district. The Vidler tunnel, which was originally started through Gray's peak for mining purposes, is to be enlarged into a railroad tunnel, for the Argentine Central railway. The tunnel enterprise was in the hands of an English company, and did not thrive under the 'absent treatment.' The company has been re-organized by local men, work has been resumed, and, with both the mining companies and the railroad interested in its success, the driving of the remaining 2800 ft. will be a short job. The distance from Leadville to Denver, by this new road, will be some fifty miles shorter, with much easier grades than by the present route.

An oil well, flowing 150 bbl. per day, has been developed in the Boulder oil field. This has stimulated others to such an extent that two new wells are being drilled, and contracts have been let for six more. The region south and east of Colorado Springs is still being prospected. Good indications have been found in some wells, but nothing new has developed.

The Cripple Creek production is meeting the usual influences for increase and decrease. Since Allan L. Burris became president of the El Paso Consolidated Mining Co., it has been decided to work the property on company account. The lessees have been given notice that their leases will expire on May 1, and they are making endeavors to remove all the ore possible before that time. On the other hand, the pumps on the bottom level of the Strong mine have been shut down. This will decrease the production from the lower levels of the Portland, Ajax, Granite, and Dead Pine mines. It was from these workings that some of the richest ore in the camp was produced. The trouble seems to be that the companies which benefited by the pumping are not willing to bear a part of the expense.

Several companies, with irrigation projects in the San Louis valley, have been disappointed recently by the decision of the Reclamation Service to refuse title to any more reservoir sites in the valley. The reason given is that the water is needed in the Engle, New Mexico, reservoir, so that the United States can furnish to Mexico 10,000 acre feet. The parties interested are protesting vigorously, claiming that the surplus water to be stored in the reservoir is to be used to irrigate private land, some of which has never been reclaimed.

MEXICO.

Chihuahua & Pacific Ry.—Railroad to Cananea.—Coahuila Coal.—Tariff on Coal and Coke.—Zinc Ore Production.

Word reaches us from Chihuahua that the Chihuahua & Pacific railroad, running west from the city of Chihuahua, has been bought by F. S. Pierson, representing a Canadian syndicate, and that he is negotiating for the purchase of the principal lumber and railroad interests of W. C. Greene, known as the Sierra Madre Land & Lumber Co. and the Sierra Madre & Pacific R. R., and that as soon as these deals are consummated the railroad will be pushed on to the West Coast. It was generally supposed that the Cole-Ryan people were after the Greene holdings, but evidently such was not the case. It is possible that the Pierson syndicate may take over the Kansas City, Mexico & Orient railroad, leading to Topolobampo in Sinaloa, but this is doubted. The difficulty of construction along the line of the Orient is great, and it is probable that the line will be sooner extended toward the northwest from Temóscochic, the present terminus of the Sierra Madre & Pacific, and thus connect with the proposed road from Nuevas Casas Grandes, and so reach up to Cananea. This would be in accord with the concession which Greene had for the Sierra Madre & Pacific R. R. Thereby three feeders would be secured, one west from Chihuahua, one south from El Paso through Nuevas Casas Grandes, and one south from Cananea. The completion of this line of the K. C. M. & O. would give Chihuahua two outlets to the Pacific. The timber,

mining, and agricultural possibilities of the country through which these lines would pass should warrant ample returns for both. Should the proposed railroad from Monclova, State of Coahuila, to the city of Chihuahua, also be built, the production from the Coahuila coalfields would have, by the two lines west from Chihuahua, an outlet to the States of Sinaloa and Sonora. This Monclova-Chihuahua line is not removed from the list of probabilities, for the preliminary reconnaissance was made by National railroad engineers some years ago, and undoubtedly both the States of Coahuila and Chihuahua would assist in the construction. In fact it is stated that Coahuila has offered a subsidy of \$5000 per kilometre. The coalfields of Coahuila need a larger market, for the production already appears to have exceeded the demand. The Rosita fields were taken over from Arturo Longega several years ago by Ernesto Madero, who interested English capital with him and so opened an immense production. These mines recently have been forced to curtail their output. The Mexican Coal & Coke Co., which has been the largest producer for many years, has cut the coal at 960 ft. in its new 24-ft. shaft, and it is

State of Chihuahua, Mexico.

believed that this shaft is in the centre or bottom of the Esperanza basin; hence through it the other shafts and workings may be drained. That would eventually make this the main working shaft. The shaft in which this company had such a disastrous fire several years ago still remains closed, and will remain so for some time. Beyond the Rosita fields, to the northwest, the Mexican Coal & Coke Co. is prospecting on new lands, and it is said that some ten or twelve million tons of coal have been proved, but no effort will be made to open them up while the production exceeds the demand. It is because of these conditions that the Mexican operators are seeking a differential railroad rate or a tariff applying on foreign coals and coke. They claim that in the Sabinas fields alone there are some 300,000,000 tons blocked out, and that already \$20,000,000 are invested there, over one million of which is in coke ovens; that in order to bring this coal and coke up to the grade of the foreign at least 15% must be washed out, necessitating expensive plant, and with the poor labor of this country, they must be protected in some way in order successfully to meet foreign competition. They furthermore state that if the consumption could be placed at 2,000,000 tons annually, the pay-roll in producing it would amount to \$10,000,000. This money, they say, should be kept at home and not be

sent abroad to pay for foreign coal. Their contentions are perhaps more soundly based than the zinc producers of the United States now calling upon the Congress at Washington for a duty upon foreign zinc ores, which in effect means Mexican ores. They affirm that the Mexican is cheap labor competing against high paid American labor, but they do not mention the difference in efficiency. They are taking fright because the entire zinc importation into the United States from Mexico last year was but 108,000 tons, an increase of about 25% over the preceding year, but scarcely in excess of the production of one good mine in the States. Of course, the zinc miner has as much right to protection as the lead miner, who has for many years been well cared for, but it looks as if the zinc miners are making a mountain out of a mole hill.

JOHANNESBURG, TRANSVAAL.

Report on Crown Mines.—Underground Efficiency.—Diamond Speculation.—Deep-Level Improvements.—Mine Managers' Examinations.—Floods.—Stope-Drill Trials.

The report of G. E. Webber, consulting engineer to the Rand Mines, Ltd., upon the Crown Mines amalgamation scheme has been issued, and in it he affirms that the property is destined to possess a "stability rarely, if ever before, met with in the history of mining." The operations of the producing mines of the group have already been noted, but additional data selected from Mr. Webber's report may prove interesting. The attractiveness of the Crown Mines from the investment point of view lies in its combination of security and speculativeness. Apart from the partly developed area above the South Rand dike, wherein $4\frac{1}{2}$ million tons of 7.94-dwt. ore stand exposed, there is the southern area untapped by shaft or bore-hole. The ore reserves of the producing units stand in relation to their crushing capacities as follows:

	Yearly crushing. Tons.	Tons developed.	Dwt. per ton.
Robinson Central Deep.	378,000	875,556	10.21
Crown Deep	474,000	1,406,838	8.8
Crown Reef	294,000	505,000	6.51
Langlaagte Deep	474,000	1,168,500	6.5

The aggregate crushing capacity is 1,620,000 tons and this will be maintained, upon the completion of the scheme, until additional tube-mills and cyanide plant are erected, which will require only a few months. Then for three years an annual capacity will be about 1,800,000 tons, subsequently to be raised to 2,000,000. Valuing the ground north of the dike on a basis of 29s. 10d. grade, and 15s. 6d. costs, a net annual profit of £1,267,000 is arrived at, while the value of the property is placed at £13,366,885.

Since the strike of miners in 1907, which ended speedily in favor of the companies, there has been a marked increase in underground efficiency. To some extent wages and contract earnings have been reduced, but the principal benefit has appeared in the raising of the standard of a day's work. Taking the ore produced per white man underground in 1908, an increase of 200 tons per annum, or 10%, can be recorded in comparison with figures for the previous year. One reason for this advance has been the employment of more highly qualified men in the positions of mine captain and shiftboss—men now mostly recruited from the ranks of technical graduates after they have served their time in the stopes and drifts. Compared with the bosses of the old school, these men may possess comparatively limited rock-breaking experience, but their wide knowledge of other departments gives them exceptional fitness for the organization of underground forces. After the strike, wages were appreciably reduced, a fact demonstrated by the Rand's aggregate distribution in wages which stands at a constant of ten million sterling annually despite the increasing number of workers. But the earnings of skilled miners have again risen, and have averaged during 1908 roughly as follows: machine-stoppers, \$7; machine developers, \$7; hand-stoppers, \$5; hand-developers, \$5.20. The average white

wage for the Rand has been slightly reduced owing to the inclusion of several hundred white men being employed on unskilled work, such as shoveling and tramping.

It is one of the characteristic features of speculation in South Africa that, however ill a mine or district may fare, and whatever may be the magnitude of the public losses on that account, it will sooner or later be re-instated in popular esteem. A case in point appears in the re-floitation of the famous Lace Diamond mine, which was one of the most wildly-boomed gambling counters five years ago. It reappears under the title of the Crown Diamond Mining & Exploration Co. Whether the time be ripe for re-opening idle diamond mines does not affect the proposition. The only circumstances holding the public mind are that the venture is being undertaken by a strong control (Lewis & Marks), and that the former handling of the property was, of course, inefficient. The Lace mine is situated near Kroonstad in the Orange River Colony, and has an area of some 400 claims (8.8 acres), or 70 claims less than the Kimberley. Sufficient money has been subscribed to provide for re-equipment on a direct-crushing basis, which is favored in all new diamond mines in preference to flooring and weathering. Completion of plant is promised for March. The proposal is to run the mine at a capacity of 5000 loads per day, which should yield 13,000 to 14,000 carats per month.

Rand deep-level prospects improve owing to the recent remarkable results in the City Deep. When the 'reef' was first cut at a depth of over 3000 ft., the prevailing idea was that only a good spot had by chance been encountered, but this supposition has been disproved by nine months of development which have revealed a large stretch of 'Main Reef Leader' of high-pay ore. The 10-dwt. grade disclosed by the first month's work has been maintained without variation, and 560,000 tons of this value now stand in sight. Such improvement in gold-content at that depth, as compared with the standard nearer the outcrop, augurs happily for future prospects in Central Rand deep-level mining, our knowledge of which will shortly be advanced further by striking the reef in the vertical shaft of the Turf Mines at 4000 feet.

Dissatisfaction with the decisions of the Mine Managers' Examining Board has long been expressed. The feeling of distrust with the system upon which the qualifications of mining engineers for managerial responsibilities are determined, have been intensified by the results of the last examination, which were so incongruous as to occasion strong comment from W. W. Mein in his presidential address before the Mine Managers' Association. Out of 23 candidates, only nine passed. This would appear in no way remarkable if the 'failures' had not included men of proved competency; men who have handled underground forces in big mines with exceptional success and have shown themselves reliable and proficient under the hardest tests of working practice. The principle of these examinations is admirable, but the system adopted is fundamentally at fault.

The deluge which resulted in the Witwatersrand mine-flood at the end of January has been followed by a series of heavy rains which have seriously affected mining operations at many points. Over 20 in. fell in January, and the first fortnight in February has not included a day without contributions to the season's abnormal record. Several mines have been obliged to temporarily suspend milling operations owing to inaccessibility of stopes or to the necessity for devoting the hoists to baling. The February output is likely to be much lower than the January rate of production would indicate as normal for the short month. Even the January yield of £2,612,836 was affected by the floods.

The surface 'elimination trials' of the Stope Drill Competition are to be commenced immediately. The preliminary arrangements have included a series of tests for the calibration of the Kennedy air-meter, which is to be used for determining the consumption of compressed air at various pressures. Though this aspect of working results will

The new North Butte Extension Development Co. seems

Boundary and Coeur d'Alene Districts.

The settlement of a \$10,000 judgment obtained by Alonzo

W. Evans of Cleveland against the Lake Shore Gold Mining Co. is contested by Evans' Butte attorney, who refuses to dismiss the attachment, and threatens to proceed against the property under the Evans judgment to satisfy his fee of \$2500. As he has possession of a block of stock under attachment he will probably win. The Lake Shore Co. has been re-organized. It owns a good mill, but its property, according to reports, is of little value.

NEW YORK.

Electric Smelting. — International Smelting Corporation. — Copper Situation.—Market Conditions.

It was recently announced that the United States Steel Corporation had decided to equip its works with electric smelting furnaces of the Heroult type. This furnace is extensively employed in steel works in France and Sweden with satisfactory results. In Germany, Switzerland, and Italy the Stassano furnace is chiefly employed. Within the past few weeks the Bonner Fräsefabrik, at Bon, has replaced its crucible steel plant by Stassano electric furnaces for the production of all the hard and mild steel used in the factory. Each furnace has a capacity of one ton of steel. The steel in this factory is made from iron turnings and factory scraps valued at \$15 per ton. The entire cost of converting it into steel amounts to \$29 per ton. Each furnace converts a ton of filings into a high-grade nickel steel in five hours. Each furnace requires two men to look after it, and absorbs 900 kw.-hr. of current. The Heroult furnace, however, is probably better suited to American conditions.

Several companies are negotiating for the purchase of the various properties of the insolvent Greene Gold-Silver Mining Co. in Chihuahua, Mexico. A Canadian company has taken an option on the large timber leases which formed one of the principal assets of the defunct concern. The representatives of the Rothschild Exploration Co., of London, are sampling the mines. It is believed that the Greene company's troubles were caused by bad management rather than through defects in its properties.

The International Smelting Corporation, the recently organized auxiliary of the American and Mexican copper trust, has purchased a number of the mines and smelters on which it had options. A meeting of the directors will be held in New York shortly, after which an announcement will be made relative to the Corporation's recent purchases and its public rates for smelting copper ore. It is estimated that the properties just purchased will enable the Corporation to declare a 10% dividend on its first year's operations. The Copper Producers' Association has issued its second report covering the statistics for the month of February. Production was placed at 114,793,000 lb., or at the rate of 3,703,000 lb. per day. The production in January was 112,136,200 lb. The copper stocks at present on hand in the United States amount to about 180,000,000 lb., or about four months' normal consumption. The announcement of these statistics depressed the copper stocks listed on the New York Stock Exchange, and gave rise to an abundant supply of gloomy predictions relative to the future of copper. Speculators in the metal are loud in their complaints against the copper miners for not taking concerted action toward relieving the present excessive supply. The outlook, however, is not so bad as it is painted. It is possible that a further cut may be made in the price of copper, with the view of inducing manufacturers to come into the market for larger quantities of the metal. But prices will not continue low very long. During the past fortnight European speculators have purchased a large proportion of the stocks on hand for purely speculative purposes. They are taking advantage of the low rates ruling for money to acquire copper for an early rise. Their plans have been conservatively laid, and these extensive purchases must be taken to indicate the betterment of the copper market in the near future. The stock market continues quiet. Fluctuations in prices range within three points. The industrial stocks are particularly sluggish. These conditions will

probably continue a few weeks longer, until investors learn from the Congressional debates the trend of the factors influencing tariff reform. The prevailing opinion in financial circles at present is that the revision will not be sufficiently serious to effect stock values. The anxiety appears, not so much as regards the proposed changes in customs imposts, as to the attitude of the representatives in Congress of the various trusts. The proposed reductions of the duties on iron ore, steel, and iron have already been discounted on the stock and metal exchanges. Brokers on the curb market report improving business in mining stocks. Nevada and Mexican gold mining stocks are much in favor.

TORONTO, CANADA.

Mineral Production. — Cobalt. — Notable Technical Papers.

J. McLeish of the Department of Mines, presented at the recent meeting of the Canadian Mining Institute a report on the mineral production of Canada in 1908, showing that the output was the largest in the history of the country, being valued at \$87,323,849, as against \$86,842,765 in 1907, this in spite of the large decrease in the prices of metals. Had the high prices of the previous year been maintained, last year's product would have been worth \$8,000,000 more. J. Obalski, Superintendent of Mines of Quebec Province, made a statement showing that the value of the mineral output of the Province was \$5,493,664, the production of asbestos alone being valued at \$2,551,596, while that of cement was \$1,127,335. The number of men employed in the mining industry was 6324. Thomas W. Gibson, Deputy Minister of Mines for Ontario, presented a statement giving the statistics of mineral production for 1908, the total value amounting to \$25,219,609, as against \$25,019,373 for 1907. While the figures showed a considerable shrinkage in non-metallic production, the metallic output was \$16,705,647, as against \$14,550,835 in 1907. The items under this head were as follows:

	Quantity.	Value.
Gold, oz.	3,465	\$ 60,337
Silver, oz.	19,424,781	9,125,903
Cobalt, tons	1,224	110,166
Nickel, tons	10,175	1,866,059
Copper, tons	7,561	1,071,140
Iron ore, tons	199,395	537,379
Pig iron, tons	271,656	4,390,839
		<hr/>
		\$17,161,823
Less value Ontario iron ore (170,215 tons) smelted into pig iron.....		456,176
		<hr/>
		\$16,705,647

The output of silver from the Cobalt district nearly doubled. Returns from 29 shipping mines showed ore and concentrate shipped amounting to approximately 25,497 tons, containing 19,296,430 oz. silver, as compared with 14,644 tons, containing 9,982,363 oz., in 1907. At the average price of refined silver for the year the production of 1908 would be worth \$10,200,865, representing an average return of 756 oz. silver, or \$400 per ton of ore shipped. The output of last year would probably place Canada in the third place among the silver-producing countries of the world.

At the sitting on March 4, S. F. Emmons, senior geologist of the United States Geological Survey, discussed the various theories of ore formation, tracing their development, and showing the predominance of the view that ore deposits are largely connected with volcanic action. He emphasized the great value to the American mining industry of the careful work of the Geological Survey, and urged upon Canadians the importance of detailed geological examination of mining districts. Waldemar Lindgren, of the U. S. Geological Survey, dealt with the subject of 'Metallogenetic Epochs', contending that at different eras, different kinds of metal had been deposited. From a comprehensive review of the ore deposits of the United States, he adduced many facts in support of the opinion that various periods were characterized by particular ores. The paper excited interesting discussion.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Voltages used on electric circuits underground vary according to many conditions, 440 being a common pressure for electric pumps. Alternating current is usually employed.

Zinc-dust as a precipitant is coming into quite general use on the Rand. At the Homestake mine in South Dakota, the zinc-dust is specified to contain 2% lead, thus taking advantage of the internal zinc-lead couple to promote the reaction with the cyanides of the precious metals.

High duty in stamp-milling is the order of the day in South Africa. At the West Rand Consolidated mine 1800-lb. stamps are being installed, which will crush 12 tons each per diem. Duties of 9 to 10 tons per diem are regularly attained by stamps weighing from 1400 to 1600 lb. in the gold mills of the Transvaal.

Rational analysis is a term sometimes used to designate an approximate determination of the mineral ingredients in clay, soil, or other substance resulting from rock-disintegration, as distinguished from chemical analysis. In the case of clays the 'rational analysis' takes account of kaolin, free silica, and feldspar.

A mining claim open to valid location is necessarily open to re-location by a former locator, but if a claim is open to re-location by virtue of failure to perform assessment work, and no one has placed an adverse location upon the ground, the original title is continued by the former locator resuming work upon the claim. This is preferable to re-location.

Amount of principal and interest, when interest is compounded, may be calculated by the formula

$$A = P(1 + r)^n$$

in which A equals amount of principal and interest, P equals principal, r equals rate per cent per annum divided by 100, and n equals number of years. For example, \$500 at 5% for 10 years would produce $500 \times 1.05^{10} = 500 \times 1.62889 = \814.445 . The factor r to the required power may best be worked out with logarithms, or with the slide-rule.

Lightning discharge, estimated from its light, according to Charles P. Steinmetz, develops an energy of 10,000 kw.-seconds. This is not as high an energy as had originally been suspected, and expressed in heat-measure it represents the latent heat of evaporation or condensation of 9 lb. of water. But estimating as disruptive strength of air under discharge conditions in a non-uniform field, the average potential gradient in the path of the lightning discharge through the clouds would be about 50,000 volts per foot.

Railway rates in Canada are fixed by a Commission of three appointed by the Governors in Council,

the term of office being ten years. The Governors have power of removal as well as of appointment. The Commission has absolute power over rates, classification, speed, safety appliances, and the like. The railways may submit tariffs, but these are rendered effective only by authorization of the Commission. The burden of proof to show that difference of treatment does not amount to unjust discrimination rests upon the transportation company.

Stannary is a name applied in Great Britain to tin-bearing districts. It was a recognized term in law as early as the 12th century, and a mining tribunal, known as the Stannary Court, was in existence from very early times. The root of the word was employed in many ways; for example the bounding monuments of mining claims were called stannaburrows; and the miners themselves were called stannators. Mining laws relating to the tin-producing districts are called Stannaries Acts, the latest general Stannaries Act being passed by Parliament in the year 1869.

Peridotite is by no means an uncommon rock, but is seldom found in large masses. Peridotites, often termed pyroxenites, are moderately basic rocks, closely allied to the gabbros. The differentiation of peridotite from the gabbros is marked by an increase in CaO and MgO, with a corresponding decrease in Al₂O₃. Pyroxene is the predominant mineral, the common accessories being enstatite, bronzite, hypersthene, and diallage or augite. Magnetite and titaniferous minerals are frequently found, and are sometimes present in quantities sufficient to constitute an ore of iron, as at Taberg, Sweden. A notable occurrence of this type is found at Cumberland, Rhode Island.

Gold dissolves in cyanide solution in direct proportion to the area of metallic surface presented. The area of a sphere equals the square of the diameter multiplied by 3.1416 ($A = \pi d^2$) and the volume equals $\frac{1}{6}$ of the product of the cube of the diameter

and $3.1416 \left(\frac{\pi d^3}{6} \right)$. Therefore, to take the

simplest conditions, if a gold particle has a diameter of 1 mm., its volume will be 0.5236 cubic millimetres, and its area 3.1416 square millimetres. For a sphere of 2 mm. diam., the corresponding figures are 4.1888 and 12.5660. The ratio of volume to surface in the larger particle is as 1 to 3, while in the smaller it is as 1 to 6. At $\frac{1}{2}$ mm. diam. the ratio becomes 1 to 12, and so on. The economical limit of size is one to be determined in the light of results. With relatively coarse gold the time of contact must be prolonged to insure high extraction. For a large tonnage it pays to install expensive machinery for fine grinding in order to obtain quick extraction by slime-treatment; for a small tonnage leaching would be cheaper. It is purely a question of what pays best, which must be ascertained by experiment. In general it may be said that gold particles, to be susceptible to economical leaching by cyanide solution, should be smaller than 0.01 inch diameter, or 0.25 millimetre.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Geological Hierophants.

The Editor:

Sir—Light-hearted jocose references to the language used in scientific writing have appeared frequently in your editorial columns, and since in your issue of February 27 you honor Mr. Calkins and me with a column and a half of such levity, it seems only fair that your readers should have a sober statement of the other side of the question.

You premise that "the reports of the Survey are intended primarily for the use of the people in the mining district serving as the subject for investigation, and after them for people interested in mining geology in the United States, and finally for scientific men." It will serve, merely for the purpose of this discussion, to accept your view, with due thankfulness moreover that you have not entirely ignored the third class.

Now the paragraph that you have illuminated with your wit and which happens to have been written by Mr. Calkins, is not, as would be inferred from your remarks, the general style of the report nor even of the chapter in which it occurs. It is found, not in the part devoted to the ore deposits, but in what is intended to be a scientific treatment of the general geology. Furthermore it is in a section that deals with the essentially technical subject of the petrography of the igneous rocks. Finally, it stands by itself as a single paragraph after the rock referred to has been described as "porphyritic syenite" and after a clear simple account has been given of its texture and mineral components. In other words, after the "average citizen" has been treated with all possible consideration for over a page, the position of the rock in a modern scheme of classification (in use by the way in the geological surveys of the United States, Canada, British Guiana, and New South Wales, and in petrological papers published in many journals and in various languages) is briefly given in words that are an integral part of that scheme and are the only ones available to convey the desired information to a trained petrographer. No writer can possibly indicate the classificatory position of a rock in this system without using the precise terms employed by its authors in their book published six years ago, of which you appear to be unaware although it is obtainable through any dealer in scientific books. Furthermore, the quantitative system is explained in Chamberlin and Salisbury's standard text-book on geology and is briefly treated with reference to more comprehensive expositions in Pirsson's elementary book on 'Rocks and Rock Minerals'. In view of these facts, which anyone who cares to can verify with little trouble, it appears that we have a deal of barking up an empty tree and that a reader more interested in the matter of the

report than in finding jokes for his editorial page need not have been greatly troubled because a rock mapped and described as 'syenite' is, in a single short paragraph, said to be named 'monzonose' in a certain well-known scheme of nomenclature.

After all, Mr. Editor, the professional papers of the Survey are occasionally read and used by scientific men as well as by laymen, and readers like yourself who suppose that Penfield (instead of Pirsson) had anything to do with this system of rock classification and see in it only something humorous may skip such paragraphs as the one you quote without any loss of self-respect and without the necessity of clamorously exposing an ignorance in which there need be no shame. Unfamiliarity with the terms of a specialty not his own is excusable in any man; but it is otherwise with that self-centred complacent attitude of mind that demands the expression of all knowledge, no matter how technical, in terms of its own daily use. Such a demand, carried to its logical conclusion, implies of course that it would be possible to explain the principles of modern chemical theory to a Fiji islander in his own tongue. That men like Huxley and Tyndall were able to expound some of the great results of science to thoughtful workingmen shows how clearly these investigators reasoned and spoke, and has left us all their debtors; but their audiences probably little realized how laborious was the task and how small a part of the total scientific experiences and achievements for which the speakers stood was communicable in popular language.

You have insisted often and well that a writer should remember his readers. But which reader? All classes of them or one only? A scientific man who prepares a paper for the *American Journal of Science*, for example, has little difficulty in this respect; he may express his results in the precise accurate phraseology that has grown with his branch of science and which enables him to say in one word what might require pages of explanation burdensome both to himself and to his well informed colleagues. In such a place a good writer will never use a word merely because it is strange or imposing in appearance nor will he hesitate to use the fit word merely because it is not in the vocabulary of ordinary life. On the other hand, the writer of an official report on a mining district labors under difficulties that few appreciate. His subject is intricate and far-reaching and necessitates incursions into various departments of science to the growth of which his investigations should contribute. But his audience is heterogeneous, ranging from the unlettered prospector who slowly follows with his forefinger the description of some lode or claim, to the well-trained investigator who rightly expects to find scientific problems treated with the conciseness, thoroughness, and penetration that belong to scientific exposition of the highest grade. Between these are readers of all degrees of intelligence and of many kinds of education and training. A little thought shows that the solution of this question, like that of so many in actual life, lies in compromise. To suppose that a report on the geology of a district like Cripple Creek

can be written so as to be intelligible in all its parts to every inhabitant of the district is clearly absurd. The writer, if his work is to have any value above that of a mere newspaper article, must suppose his readers to have some knowledge of chemistry, physics, mineralogy, petrography, geology, and the English language. That he should write as clearly as possible and should so far as is practicable segregate the most abstruse portions of his work so that they can be passed over by those unable to cope with them is obvious. It is not to be expected, however, that any one reader of a thorough scientific report on a mining district, unless he is himself a well-trained geologist, can comprehend all of its pages; but he may profitably remember that matter meaningless to him may be the most useful to others and that it is not possible to include in every geological work, elementary and advanced treatises on the various branches of allied science, a dictionary and reprints of pertinent periodical literature.

In conclusion, I request that having had your jokes at our expense you will do us the justice and courtesy to print this reply without facetious comments. If it may serve to evoke some serious discussion of the problem of making geological reports on mining districts more useful and instructive to all interested—miners, editors, investors, and scientific students alike, Mr. Calkins and I shall feel that we have pointed a moral to some real purpose. We may appropriately express, moreover, the earnest desire of many that reputable mining journals should at all times rise superior to the practice of deliberate misrepresentation and exaggeration of a kind that appeals to ignorance and prejudice and which characterizes particularly that part of the daily press in which sensationalism is exalted high above truth.

F. L. RANSOME.

Protection of Investors.

The Editor:

Sir—Apropos of the recent discussion by the Pacific Coast division of the Mining & Metallurgical Society of America, may I be permitted to make a suggestion? It would seem sequentially appropriate and another effective stroke at the root of evil to take up the subject: 'How shall mining engineers be protected against unscrupulous company directors and promoters?'

It is generally well known among mining engineers that it is not uncommon practice for promoters or directors to 'cull', distort, and re-arrange the sequence of figures and statements contained in reports to such an extent as, while not altering the phraseology, to eliminate and obscure the original conclusions, in an effort to enthuse present and prospective investors.

When the 'hot water level' is reached with the shareholders, the sins are placed upon the head of the unfortunate engineer, after which he is suffered to escape into the wilderness. Generally the only access that the engineer has to the shareholder is through the director or promoter, and perhaps he does not obtain these manipulated conclusions until

long after they have been well digested, and even though a belated protest should be filed, it would be difficult for the engineer to reach and convince the investor that he was not a party to the transaction at the time.

Of course, the engineer can have recourse to the law, but this might be distasteful for financial reasons, or the greater danger of being branded as an aggressive and offensive person to deal with. Another evil, the correction of which would be enthusiastically greeted by engineers, is the practice indulged in by presidents and other directors of companies, of dictating the technical policies to be followed, for which the engineer is made responsible to the shareholders. It might be urged that the engineer should not permit this, should resign, etc., but he may be interested in the business, and have some hope of being able to correct the condition while he remains, whereas by retiring all chance would vanish.

The excuse generally advanced by directors, for not publishing everything in their reports to the shareholders, is that some features may not be understood by the 'layman' shareholder, as a result of which a panic in the shares might be precipitated, to the detriment of all concerned. This, in the minds of some directors, justifies the frequent 'juggling' with engineers' reports.

With such fearless, instructive, and clearly stated matter as is furnished nowadays by the MINING AND SCIENTIFIC PRESS and other representative journals, I venture to say that the average shareholder should be as well equipped with knowledge of the eccentricities of nature's distribution of mineral and just as able to anticipate market fluctuations as the average company director, especially in England, where the qualifications of company directors centre largely round the rank of baronet or other distinguished title, provided, of course, that the shareholder has had the same amount of data to begin with. If not, it would indicate that the shareholder was either not fully enough advised or was possessed with inferior mental ability, and needed a guardian for his funds.

As far as I am aware, there is no fixed understanding between the directorate of a mining company and a prospective shareholder, that when the former is soliciting the sale of shares, the shareholder must place himself, body, soul, and pocket in the hands of the directors, and that many important mineralogical and economic changes will occur during their business association, of which he will not be advised, for his own good.

It seems to me that good results are sure to follow from the recommendations of the committee appointed by the Pacific branch of the new Society, and these, after boiling down the recent discussion, could be extended to the point of becoming mutually protective, alike to the investor and the engineer, to the end that there should be a means of direct communication between them, in so far as they are concerned, without straining the relations between the director or promoter and the engineer, and by which the responsibilities for good or defective financial or

engineering results, could be accurately and readily fixed.

F. C. ROBERTS.

San Francisco, March 2.

The Engineer as a Financier.

The Editor:

Sir—I have read Charles R. Gent's letter, published under this heading in your issue of February 27, with much satisfaction. I think that he has hit the nail on the head, and I should like to drive it in a little further. Mr. Gent submits, in contrast to the stand taken by certain of your contributors, that no judge is permitted to try a case in which he has even the least interest. This rule has been established in recognition of human moral weakness; its wisdom and justice are too obvious to need discussion. Engineers, as men, are morally not stronger than judges.

It seems to me that in this discussion there has been too little recognition of the fact that, in different walks of life, the barriers that may not be passed also differ. There are things that professional men cannot do, that are permitted to others. And of all the professions, that of mining engineering requires, perhaps, the greatest integrity, because it involves a subject of peculiar difficulty and hazard, as well as the investment of great sums upon a single man's word.

An engineer's report is supposed to be, and should be, without bias. His usefulness in mining depends upon impartial presentation of the truth, as well as upon his ability to determine the truth. An engineer when in practice acts for others, primarily. His true success must lie in correct and profitable work for others, and his reward must be confined chiefly to enhanced reputation, with the enlarged practice and increased fees resulting. I think it cannot be disputed that when an engineer finds his way to financial comfort too short and attempts to become a financier, he ceases to be, exclusively, a professional man. He becomes a business man and his business interest takes precedence. Right there is the focal point of this discussion.

A business man is supposed to be, and must necessarily be, biased. He must see things from the view-point of his own interest and he must impress that view-point convincingly upon others; for his competitors are doing the same thing, always. This is expected and permitted; furthermore, it is a recognized factor in business dealing, and, as such, it is discounted.

Professional honor and business honor differ so fundamentally that any attempt to reconcile them, by whatever sophistry, is futile. An engineer who finds that finance in connection with mines attracts him, may quite properly try that field, but he can hardly be said to play the game fairly with himself and with his public when he attempts mining finance under the cloak of his profession. As an engineer, he is expected to present the truth impartially, even nakedly. But when he undertakes a case wherein a favorable report will benefit him more than an adverse one, then he at once becomes a business man,

dealing for his own interest and at arm's length, in spite of himself. If his true position were recognized and his report discounted as a business report would be, the ethics of the case would fit; but this is very rarely the case and more rarely the intention. Stripped of all arguments that have been reared to support this false position, it really amounts to this: That the underlying, unmentioned advantage that can accrue to an engineer acting as a financier (in the sense meant in this discussion), is that his report, made with the inevitable bias of a business transaction, shall be accepted, at face, as a report made by a professional man who is supposedly paid for the truth only, and whose whole interest is believed to lie in determining the truth correctly and in telling it exactly.

Is it not this unacknowledged advantage that makes necessary so much argument, so many excuses; and, per contra, that makes the field so alluring? We all know that some men have managed to gather fortunes in this field without being soiled. But how far good luck has counterbalanced rashness, we do not know. When an engineer finds the desire for wealth overshadowing the intellectual rewards that his profession offers, he should, perhaps, withdraw from practice and try finance. In most cases he will be glad to return to practice; and generally he will do so with accumulated debts and burnt fingers. If his professional record has, in the meantime, been kept clean, he may perhaps find opportunity to heal the sore places.

ARNOLD BECKER.

Santa Barbara, March 7.

Silundum is a form of carborundum, and has similar properties; it is very hard, resists high temperatures, and is acid-proof. It is a conductor of electricity, its resistance being about three times that of carbon. The hardness is variable, and depends on the zone around the core in which it is produced: material from the amorphous zone is less hard than that obtained in the crystalline zone. Silundum is fire-proof to a high degree: it can be heated in the air up to 1600° C. without oxidizing. At about 1700°, however, the silicon leaves the carbon and combines with the oxygen of the air. Silundum cannot be melted. The electric resistance of this material depends on the kind of carbon and its hardness: made from porous carbon it has a higher resistance than that from hard carbon. The resistance depends also on the modification of the material; in the amorphous zone the resistance generally is higher than in the crystalline zone.

Ferrous iron in rocks and ores is affected by the method of preparing the sample. Mauzelius of the Swedish Geological Survey noted that fine grinding has a decided influence on the proportions of FeO and of H₂O in the powders. Grinding was performed in air, under water, alcohol, and under various other media. The explanation of the phenomenon seems to be that of "strong local heating of the grains at the moment of fracture or attrition under the pestle."

MECHANICAL ELEVATOR.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

Among the machines devised for the exploitation of the gravel deposits of the North, one that gives promise of usefulness is the mechanical elevator operated during the past season on Bonanza creek, near Dawson, in the Yukon Territory. I had an opportunity of examining one of these elevators while it was at work, last July. Three of the machines had been ordered by the Yukon Gold Co., and two of them were in process of construction at the time of my visit. The No. 3 elevator, so called, was at work on the claim known as 3 Above Discovery on Bonanza.

The mechanical elevator was especially designed by the engineers of the company to meet the conditions found in certain portions of the Klondike creek deposits, where the gravel is shallow and largely frozen, and where the gold itself is found for some distance within the bedrock. The method of working is a combination of hydraulicking and elevating; therefore, it involves the use of electric power as well as water under pressure.

The obstacle to straight hydraulic mining as applied to shallow creek-gravel is the absence of sufficient grade on the bedrock to sluice the gravel and dispose of the tailing. While such gravel can be dredged, and, in fact, has been dredged successfully, the chief objection to the dredging method is that the gold is distributed at varying depths in the bedrock. The inability of the operator to see the bedrock, and, in some cases, the hardness of the material encountered, render complete extraction unattainable by this method. It was to overcome the difficulties attendant upon either the hydraulic or dredg-

steel tower supporting the series of buckets that elevate the gravel. Thus grade is obtained at both ends of the operation.

No. 1 Elevator at 30 Below on Bonanza Creek, Showing Arrangement of Pumps

A description of the elevator will serve to make clear the functions it performs. A pit or excavation 100 ft. wide and 200 ft. long marked the area

Monitor

Ground-Sluice

Elevator

Sluice-Boxes

Mechanical Elevator in Operation at No. 3 Above on Bonanza Creek, Dawson.

ing methods that the mechanical elevator was designed.

The fundamental features of the device are: (1) the creation of artificial grade; and (2) obtaining room for the disposal of tailing by the erection of a

that had been stripped of gravel nearly to bedrock. The latter consisted of soft schist, tilted against the flow of the creek, so that the laminae were thrust upstream and made natural riffles. If the schistosity had been down-stream, the result would have been a

smooth bed unfavorable to the concentration of gold. This placer on Bonanza creek was only 12 ft. deep, mainly clean gravel; the composition of the deposit varied, for it had been worked in spots in the early days, so that sundry accumulations of tailing gave additional depth. Signs of former drift-mining were indicated by old timbers. Being in a live stream there never was much 'muck' and most of it has been removed by the former operators.

At the lower end of this broad shallow pit, a steel structure stood more than 40 ft. high, carrying the bucket-conveyor. At the top, the buckets emptied the gravel into the gold-saving sluices; at the bottom, they descended into a sump or well and scooped up the material driven thither along a ground-sluice, and over the bare surface of the bedrock, by a strong jet of water delivered from a monitor.

The frame of the elevator is made of structural steel, so as to embody strength with lightness; it is in the form of a tower 49 ft. high; at the top it is 12 ft. by 16 ft. 8 in.; at the base, 12 ft. by 23 ft. 6 in. This frame rests on timbers set in the bedrock. When completed the elevator will have a frame standing on cross-girders carrying double-flanged steel wheels to facilitate moving ahead when a cut is finished. The machine is not fixed; it is intended to be shifted as the ground is worked out. Underneath, and in front of the base, is the pit that serves as a sump or well for the water and gravel. These are elevated by a close-connected bucket-line. The buckets have a 24-in. pitch, the steel bottom serving as a link between them. Each bucket has a capacity of 3 cu. ft.; there are 76 on the line and the movement is such that 24 are discharged each minute. They discharge into a hopper emptying directly into a sluice 3 ft. wide. The first sluice-box (12 ft. long) has a gradient of 10 in.; the second, 9 in.; the third, 7 in.; and the fourth, 6 in. per 12 ft. Ordinary wooden riffle-boxes are laid along the bottom. It is intended to use steel sluice-boxes with the next elevator plant; they will be lined with steel bars $1\frac{1}{2}$ by 1 in. bolted to a strip of wood $1\frac{1}{2}$ by 6 in., thereby making a riffle $1\frac{1}{2}$ in. wide by 7 in. deep.

The pit is kept clear of the water resulting from the hydraulicking and natural drainage by a 12-in. Morris centrifugal pump, assisted by a hydraulic jet, delivering a steady flow of water to the head of the sluice-boxes. Owing to the presence of fibrous material, derived from the roots in the overburden, when stripping the gravel deposit, there has been some difficulty and interruption to steady work. The runner-chamber becomes clogged. This difficulty will be remedied by devising a pump the chamber of which will afford plenty of clearance and be readily accessible.

The empty buckets, in their descent, pass over an idler, specially designed. It consists of steel links pin-connected and shod with manganese-steel plates. This idler is essentially a chain-belt running upon stationary rollers, which are mounted on an elliptical cast-steel frame. The frame is only half of an ellipse, the links hanging free throughout the latter portion of their travel.

The vertical distance from the top to the bottom

tumbler is 58 ft. 9 in. The motor stands on a platform 26 ft. above the bedrock; the drive is effected by a 50-hp. slow-speed motor belted direct to a 58-in. diam. pulley.

The mining operation itself consists in stripping the ground in front of the elevator by the use of monitors placed advantageously, so as to make the most of the driving power of the water issuing from the nozzle. After the ground has been stripped, the rich gravel is reached and is driven into the pit at the lower end of the excavation, where it is lifted by the chain of buckets. Then the bedrock is swept clean and as much of the soft superficially weathered rock is piped into the pit as a pressure of 140 lb. per square inch (or 350-ft. head with a 3-in. nozzle) will permit. The delivery of material into the elevator-pit is regulated by the piper or nozzle-man acting in harmony with the man in charge of the sluice-boxes. They signal to each other whenever necessary. Finally, the bedrock is dug, by pick and shovel, for about a foot deep, the fragments being swept with wire brushes and whisk-brooms into the ground-sluice, as in ordinary hydraulic mining. The object is to clean the bedrock thoroughly. One man will clean 15 to 20 feet square per shift.

The nominal capacity of the No. 3 elevator was rated at 4000 cubic yards per day; the actual work done was equivalent to 1500 yards. The buckets were about half-full; if filled, the material lifted would exceed the capacity of the sluice-boxes, which were set on inadequate grade because of lack of room for disposal of the tailing. This will be remedied when the elevator is moved up-stream. It is expected to move the plant twice, if not three times, each season. The last move would be made at the end of the season, so as to have the elevator in position ready for work at the commencement of the next season. When moving, the chain of buckets is disconnected and dragged ahead by means of a cable: the lower tumbler and the ladder structure below the level of the bedrock are also detached and shifted in the same manner. The remainder of the machine will be drawn forward bodily on wheels running over 50-lb. rails. The frame will be made rigid by stiff-legs on each side, so as to prevent tipping while removal is in progress. The power consumed in the operation of the mechanical elevator is estimated at 200 hp.; the bucket-line requires 35 hp.; and the pumps, 165 to 175 hp. From this it is evident that the pumping constitutes a large part of the work performed. Power costs \$8 per hp.-month.

Some tests made by the writer with a pan proved the richness of the gravel lying upon the bedrock. Five full pans, together equal to a cubic foot, were washed. The yield from the rich layer, one foot thick, on the bedrock was \$5 worth of gold, that is, \$45 per square yard of bedrock. The deposit was 18 ft. deep, so that 6 cubic yards were moved per square foot of bedrock, giving an average yield of \$7.50 per cubic yard. This was about double the estimate of average production at this spot, as I was informed by George T. Coffey, the superintendent of the Yukon Gold Co.'s hydraulic mining operations.

A stiff-legged derrick, with a 30-ft. mast and a

The No. 3 elevator operated satisfactorily until the close of the season, on October 10.

It is obvious from the above description that the operation differs from hydraulic elevation mainly in the substitution of electrically-driven mechanical elevators for the hydraulic device employed in the operations at Nome and elsewhere. A saving is obtained by reason of the high efficiency of the mechanical elevators and the cheapness of electrical power as compared to the great expense of water in the Klondike district. The experiment has demonstrated that where cheap hydro-electric power is available it is more economical to use this combination of mechanical elevators with a relatively small pressure-water installation, than to bring the large volume of water required for hydraulicking and for lifting the gravel by the ordinary hydraulic elevator. However, the mechanical elevator as used at Dawson must be deemed an experiment until the engineers in charge publish the figures of cost.

Gas-fired furnaces have many advantages over those heated by solid fuel, especially when a high temperature is required. When crucible-steel is melted in the old-fashioned coke furnaces, from 2½ to 3½ tons of hard coke are required per ton of steel melted, the exact amount depending upon the temper of the steel and its consequent fusing point. With a Siemen's regenerating gas-furnace, one ton of steel can be melted by the use of 25 to 30 cwt. of ordinary screened 'slack', costing only about 15% of the value of the fuel consumed in the coke furnaces. The total heat utilized in the melting of the steel in the Siemen's gas-furnace was found by J. W. Hall to be 2.38% of the calorific power of the fuels, as against 1.43 in the coke crucible-furnace. A hot-blast does not help matters in some gas-furnaces, as the gases are expanded too much, and local intensity of heat lost. Fletcher, who brought out a blow-pipe to work with hot air, had to withdraw it, because he found it actually reduced the temperature of the flame. Again, throwing burning gases onto cold metal checks combustion, and better results are usually obtainable by allowing ample space in which the gases may burn.

Platinum should be looked for in borax glass when testing for the presence of that metal. The finding of Pt in an ore not believed to contain it led to the examination of the assay reagents. The borax glass only was found to contain it. In the particular lot examined 1.3 parts per million were found. Borax fused in Pt dishes was found to take up perceptible amounts. The largest amounts of Pt were found in Merck's "m.g.r. puriss. borax."

Pressure-drop of steam may be figured by the formula:

$$p = 222.2 \, G \, L \, v^2 \, D^2 \times 10^6$$

which gives results in lb. per sq. in. G = specific weight of steam in lb. per cu. ft.; L = length of pipe in ft.; v = velocity of steam flow in ft. per sec.; D = diam. of pipe in ft. It is also found that the resistance offered by each valve in the pipe-line is equivalent to that of 53.8 ft. of additional pipe.

BEARING METALS.

As regards the characteristics of anti-friction alloys for average bearings, the structure largely depends on the composition, for while heat-treatment will affect the apparent structure, it is chiefly in regard to size of crystals. For example, the binary alloy antimony-lead, consists of crystallites of lead in a eutectic matrix if the antimony is below 13%. If over 13% crystals of antimony form in the eutectic matrix. A good bearing metal must have a hard constituent to support the load, and a soft constituent as a plastic support for the hard grains. Lead and antimony alloy in all proportions, and as the antimony increases the alloy becomes harder and more brittle. The only proportion free from segregation is the eutectic with 13% antimony. With less than 13% antimony the mass consists of crystals of lead and eutectic alloy; with more than 13% antimony, crystals of antimony and the eutectic. As an anti-friction alloy should consist of hard grains which carry the load, embedded in a plastic matrix to give it the property of molding itself to the journal and its irregularities, without undue heating, and as such a condition is met with in alloys above 13% antimony (eutectic), those with 15 to 25% are the most suitable. It may be conceded, however, that in the alloy with 13%, while the friction is higher, the wear is greatly diminished, and where pressures are light this is a great advantage. Dr. Dudley, of the Pennsylvania Railway Co., has adopted the 13% alloy as the best all-round bearing metal for railway work. Lead is the best wear-resisting metal known, and with increasing antimony the wear is more marked, due to the splitting-up of the hard particles, but the friction becomes less and the temperature of running diminished. The harder the alloy the more difficulty there is of accommodating itself to a perfect bearing, and the greater the liability to heating. The compressive strength increases rapidly on the addition of antimony to lead, but varies little between 14 and 30% antimony, but afterward rises steadily. The compressive strength in the 14 to 30% alloy is nearly the same as that of the eutectic. Beyond this the crystals of antimony become more united and form a more continuous network; they then bear a portion of the load and the strength increases. But the crystals of antimony have no plasticity, and break when the load reaches a certain limit, and the alloy is reduced to fragments. Hence the necessity of having great strength and plasticity in the matrix, and this is better done with ternary than with binary alloys. Babbitt metal is a tin-antimony-copper alloy, consisting of tin 89%, antimony 7, copper 4. Tin-antimony alloys with 10 to 40% antimony, after freezing, give cubes of the compound antimony-tin whose proportion is greater the greater the antimony. They are less hard and brittle than pure antimony, and the soft metal which surrounds them appears not of a eutectic structure. Alloys of copper and tin containing 5 to 50% copper are composed of hard crystals of the compound SnCu_{11} , surrounded by a eutectic of tin and SnCu_{11} . The latter crystallizes in hard needles that stand out in relief after polishing.

WHAT IS AN ORE?

By JAMES F. KEMP.

*The definition of a perfectly familiar word sometimes involves unexpected difficulties when we are confronted with the necessity of its expression in unmistakable language. The more familiar the object noted by it the greater is the surprise of one who finds himself obliged both to delimit from everything else and to put into other words the essential characters. Nothing is more familiar to the mining fraternity than the word 'ore.' So familiar is it that not every writer of a book on a mining subject has even thought of its definition, having obviously taken for granted the fact that everybody knows what ore is. There are nevertheless some striking differences to be found in the published works, and it may not be without interest to set the matter before the Canadian Institute and see what the impressions of its members are upon the subject.

The variation in the conceptions of ore largely rests upon the double use of the word both in a purely scientific and in a technical sense. Sometimes this contrast is not fully appreciated. It will doubtless be admitted by all that there is a group of metalliferous minerals that has been the source of the metals in mining and which as a class may therefore be set aside as 'ores.' Thus, if I have in my hand an ounce fragment of specular hematite, I may properly say it is an ore of iron. It is a well-known and important member of the group of minerals that has furnished iron to commerce. But if I show you a supposed mining property with only an ounce of specular hematite in it, and in this connection refer to it as ore, you would laugh scornfully. We must therefore carefully discriminate in our minds the connection in which the word is used. To this technical use I shall pass shortly, since it is the main point of interest, but I wish to clear away a few other preliminaries, relating to the use of the word 'ore' in other senses.

In the microscopic study of rocks we have learned that minerals crystallize from a molten magma in a fairly definite succession, and that the earliest group embraces magnetite, ilmenite, specular hematite, pyrrhotite, and one or two rarer metallic minerals, besides several non-metallics, such as apatite and titanite. We often denominate all these taken collectively the group of the 'ores', as contrasted with the ferromagnesian minerals; with the feldspars and feldspathoids; and with quartz. But we may set aside this use as not bearing in an important manner upon the question.

It is a time-honored conception of an ore, that it should consist of a metal in composition with some non-metallic substance, such as oxygen or sulphur, which disguises its metallic qualities and which is called a 'mineralizer.' Native metals are not 'ores' according to this view. The copper of Lake Superior is therefore obtained from 'copper-rock,' not from ore. Gold is yielded by 'gold-quartz,' not by gold

ore. But I think we must all feel that this old-time usage is no longer sharply observed and that it may well enough drop out. Thus in T. A. Rickard's interesting little book on 'The Copper Mines of Lake Superior' we certainly find the output of the mines referred to as 'ore.'

Sometimes also in the mining of the non-metallic substance sulphur, the output of the mine is called 'sulphur-ore,' although no metal is involved at all. Yet, while we may not especially controvert this usage, it cannot be said seriously to affect the general and large conception of 'ore' as limited to the metalliferous minerals. Finally the word is used by Milton and other early English writers as meaning a metal itself, artificially produced; but, of course, this use of 'ore' is obsolete.

Let us now set in order the definitions which have been proposed and which treat of ore in its technical sense. We may then examine them somewhat critically and determine whether they satisfactorily formulate our present conceptions.

The most inclusive and sweeping of the definitions that I have found is one given by R. W. Raymond in 'A Glossary of Mining and Metallurgical Terms,' in Vol. IX of the Transactions of the American Institute of Mining Engineers, 1881.

"Ore. 1. A natural mineral compound of the elements of which one at least is a metal. The term is applied more loosely to all metalliferous rock, though it contain the metals in a free state, and occasionally to the compounds of non-metallic substances, as sulphur ore. 2. Corn.† Copper ore; tin-ore being spoken of in Cornwall as *tin*."

Obviously the above definition is open to grave objection. Thus, any mineral which contains a metal as one of its elements without regard to amount would be included. Hornblende with 5% iron would be an ore. Some other mineral with 0.5% iron or manganese would equally come within its provisions. To be at all satisfactory we must delimit far more sharply and upon some other basis. Yet from the associations in which the definition appears, one would anticipate a technical rather than a purely scientific expression.

William Humble, an English writer in a 'Dictionary of Geology and Mineralogy', etc., 1860, gives the following:

"Ore. (*erz* Germ.) A metallic compound. Metals are found usually combined with other substances; the compounds they thus form are called ores when the metal exists in them in sufficient quantities to form a considerable portion of the mass."

This definition introduces the idea of quantity, but not as yet in an altogether satisfactory way, the adjective "considerable" not being definite. At what point do percentages pass from considerable to inconsiderable? Is not 20% iron considerable, yet it would not warrant mining. Is 0.0008% considerable, and yet it might justify mining for gold. The word 'metallic' being sharply used in mineralogy for a variety of lustre, is also objectionable. We might question whether calamine, cerussite, siderite, and

*Read before the Canadian Mining Institute, Montreal, March 4, 1909. By courtesy of the author.

†Corn. i.e. Cornish.

many other well known ores would be included in the definition. Metalliferous is, of course, better.

Let us take now the two dictionaries which twenty years ago were chiefly cited in English-speaking North America. Worcester (1905 ed.) states: "Ore. 1. A mineral body which is reduced to the metallic state by fire; a metal chemically combined with some mineralizing substance which completely disguises its usually recognized and useful properties."

The first sentence of the definition is objectionable, since wet methods are no less serviceable than fire, in reducing the metals, and this delimitation for ore is obviously ill-chosen. The second sentence brings out the time-honored conception earlier discussed. It is flatly contradicted by Webster, whose definition will next be given.

"Ore. 1. The native form of a metal whether free or uncombined, as gold, copper, etc.; or combined, as iron, lead, etc. Usually the ores contain the metals combined with oxygen, sulphur, arsenic, etc. (called mineralizers). 2. (Mining.) A native metal or its compound with the rock in which it occurs, after it has been picked over to throw out what is worthless."

The first portion of this definition is so condensed in statement as to be literally meaningless. Thus as the word 'native' is used in connection with metals, it distinctively means uncombined. How then could the native form of a metal be "combined as (presumably 'in the case of' to be supplied) iron, lead, etc.?" We may infer that "native" means natural as opposed to artificial, but unless a reader knows more about the meaning of ore than good Noah Webster himself did, this definition will contribute little to clearness of thought. Curiously enough the second definition is scarcely better. Can a native metal be "compounded" with a rock? We usually employ in these senses compound to mean chemical union. Again, is the product of a mine never 'ore,' until it has been sorted over? Surely the majority of us would impose no such condition.

We come next to a series of definitions in which a distinction is made between the scientific use and the technical use and into which for the latter, the condition of profit is introduced as a feature, although it is not always insisted on as essential. The late J. D. Dana expresses his views as follows in his 'Manual of Mineralogy,' 1884:

"An ore in the mineralogical sense of the word is a mineral compound in which a metal is a prominent constituent. In the miners' use of the term, it is a mineral substance that yields by metallurgical treatment, a valuable metal, and especially when it profitably yields such a metal. In the former sense, galena, the common ore of lead, is, if it contains a little silver, an argentiferous lead ore; while in the latter, if there is silver enough to make its extraction profitable, it is a silver ore. Further than this, where a native metal, or other valuable metallic mineral, is distributed intimately through the gangue, the mineral and gangue together are often called the ore of the metal it produces.

The Century dictionary contains a definition, pre-

sumably by J. D. Whitney, which is essentially the same.

"Ore. 1. A metalliferous mineral or rock, especially one which is of sufficient value to be mined. A mixture of a native metal with rock or veinstone is not usually called ore, however; it being understood that in an ore proper the metal is in a mineralized condition—that is, exists in combination with some mineralizer, as sulphur or oxygen. The ore and veinstone together constitute the mass of the metalliferous deposit, vein or lode. The ore as mined is usually more or less mixed with veinstone and from this it is separated, as completely as may be convenient or possible, by dressing. It then usually goes to the smelter, who, by means of a more or less complicated series of operations, frees it from the worthless material, which still remains mechanically mixed with it, and also sets it free from its chemical combination with the substances by which it is mineralized."

The Standard dictionary, whose definition presumably passed under the eye of either W. H. Pettee or N. S. Shaler, is shaped along the same lines, as follows:

"Ore. A natural substance, sometimes forming part of a rock, containing one or more metals. The term is applied usually to a mineral from which the metal can be profitably extracted; but is sometimes extended also to non-metallic minerals, as sulphur ore."

In these three it is a little uncertain whether when Dana and Whitney say, with regard to profit, "especially," and when the Standard says "usually," they mean in the technical as contrasted with the scientific use or not. No one of them absolutely prescribes this condition, and a reader is somewhat uncertain whether it is essential or not. In definitions it is doubtless better to leave no ground for uncertainty or confusion of thought.

In Prime's translation of von Cotta's 'Treatise on Ore Deposits,' New York, 1870, we find the following: "Under the general term 'ores' are comprehended all minerals and mineral aggregates, which, from their metallic contents, attract the attention of the miner. 'Metalliferous deposits' are therefore for us all local accumulations of minerals or mineral aggregates which correspond to this demand. The idea of the terms 'ores' and 'metalliferous deposits,' in mining parlance, cannot be well expressed in a more precise and scientific manner. There is not any particular class of minerals or of rocks corresponding to these terms. To them belong native metals, metallic oxides, metallic sulphides, and even metallic salts, and their combinations; but on the other hand not all metalliferous species of the mineral kingdom, because many of these cannot, either from their nature or the too small percentage of the metal they contain, proportionally to its worth, be worked with profit. No rock, for example, containing 5% iron oxide can be considered an ore; while on the other hand, a vein of quartz, with but 1% gold would be regarded as a very rich and valuable metallic deposit, so relative is the idea. It is even possible, and has already occurred, that a mineral which for a

long time was useless to the miner, and on this account was not considered an ore, has, by means of new discoveries, been included in the category of ores. Blende, for example, when it did not contain valuable metals, could hardly have been considered formerly as an ore, though commonly defined as such; but since a method has been discovered of extracting zinc from it with profit, it may be ranked without doubt among the ores."

The idea or condition of profit enters here, but it would appear that the authors intended to define an ore according to the condition that the metalliferous deposit should attract the attention of the miner; that is, it should be a deposit out of which at the outset the miner thinks he can make a profit, whether the result justifies his expectation or not. There is a possibility in this of which I will make further mention in conclusion.

We now come to a group of definitions which clearly treat of ore in the technical sense, and which base the meaning upon the possibility of profitable extraction or treatment. In Murray's New English dictionary, 1905, the most comprehensive of its kind, we find:

"Ore. A native mineral containing a precious or useful metal in such quantity and in such chemical combination as to make its extraction profitable."

This definition is clear-cut and concise. We are reminded, however, that an ore is sometimes an aggregate of several minerals, any one of which perhaps if considered by itself would not be profitable, yet the sum total is. In the low-grade ores of the Boundary district, the little gold and the little silver that are present are important factors in the total, yet no one of the three metals alone in these percentages could constitute an ore. It would have been well to have added after native mineral the expression "or aggregate of minerals" to allow for such cases.

In the 'Universal Encyclopedia and Atlas,' published by the Appletons in 1901, the following definition by Thomas Eggleston appears. It is taken from Johnson's Encyclopedia published twenty years earlier, and of which the Universal is the continued revision.

"Ore. A metal chemically combined or in the native state, mechanically mixed with other substances, which render treatment necessary to separate it. In a strictly technical sense, only those substances are ores which contain the metal in sufficient quantity and of sufficient purity to make the treatment profitable. Arsenopyrite, a combination of arsenic, sulphur, and iron, contains 34.4% iron, but it is not an ore of iron because the metal made from it is not of sufficient commercial value to pay the expense of treating it."

In the same volume the expression "ore deposits" is defined by R. Pumpelly and Charles Kirchhoff along the same lines, but a distinction is drawn between ore and gangue.

In other works of similar scope, like the 'New International Encyclopedia,' recently published by Dodd, Mead & Co., very much the same definition appears. "Ore deposits, the name applied to deposits or accumulations of metalliferous minerals or

ores found in the earth's crust. The term ore includes those portions of the orebody in which the metallic minerals form a sufficiently large proportion to make their extraction profitable; aside from these, there are often quantities of associated non-metallic minerals forming masses containing little or no metal, which are termed the gangue."

Authors of books on mining are inclined to look with favor on the same line of attack. In the 'Manual of Mining' by M. C. Ihlseng and E. B. Wilson, New York, 1907, after a paragraph treating of the native metals we find:

"Ores. With the few exceptions (i. e., the native metals) the metals are found in chemical union with non-metallic substances, more or less completely segregated to constitute mineral. Any accumulation of mineral of good quality and in sufficient concentration to warrant the expenditure of energy for its extraction is an ore. Manifestly this is a fickle term, since it depends for its stability upon the casual conditions of the market as well as upon the mineralogical features." In a glossary at the close of the work, there appears: "Ore. A mineral of sufficient value (as to quality and quantity) which may be mined at a profit."

The short definition from the glossary is a little infelicitous in form, and a little sweeping in statement. It would, of course, include coal, asphalt, ozokerite, and other non-metallies, which the greater number of us would certainly hesitate to call 'ores'. The longer statement introduces the term 'mineral,' which deserves a word of comment. Aside from its general meaning, under which are included substances of inorganic origin as against organic, the word 'mineral' is used, in the United States at least, to designate in the large way the objects of mining, without special reference to profit or loss. Thus the law affecting the Public Lands recognizes "mineral claims," but either from a disinclination on the part of its framers to enter into the question of profit or loss, or else from a desire to embrace also possible non-metallic deposits, mineral is consistently used instead of ore. Thus C. H. Shamel states, in his valuable treatise on 'Mining, Mineralogical, and Geological Law,' New York, 1907:

"We may summarize the American law as to the legal definition and meaning of the word 'mineral,' when used in deed, leases, or other legal instruments, as including in the absence of special provisions in such instruments, all metallic minerals of sufficient value to justify mining and extracting the same, whether for the purpose of reducing the metal therefrom or some other industrial use. It also includes rock used for building materials, etc., coal, petroleum, and natural gas. Kaolin, brick-clay, slate, etc., have not been passed upon by the American courts; but on the authority of the English cases, and the decisions of the land departments herein-after mentioned, the probabilities preponderate that the courts will hold them to be included under the term 'mineral', the same as granite, marble, etc."

In the paragraphs immediately following in the work cited, Shamel reviews the meaning of 'ore' in the few cases in which it has been defined by the

courts. The definitions are in the purely scientific rather than in the technical sense. The courts apparently prefer 'mineral' to 'ore,' wherever possible.

A definition very similar to the one from the glossary of Ihseng and Wilson, is to be found in the 'Coal and Metal Miners' Pocketbook,' which is published by the International Correspondence School, of Scranton:

"Ore. A mineral of sufficient value (as to quantity and quality) to be mined at a profit."

As remarked above, this definition, of course, includes all manner of non-metallic minerals.

Several definitions from works on ore deposits will perhaps not be without interest. Thus in 'A Treatise on Ore Deposits,' by J. Arthur Phillips, revised by Henry Louis, 1896, we find:

"Metals which occur in a state of approximate purity are said to be 'native,' and when two or more such metals are found in combination the substance is called a 'native alloy.' Usually the metals sought after by the miner are, however, not found in the native state, but are mineralized by being united with various non-metallic bodies. In this way they combine with sulphur or chlorine, giving rise, respectively, to metallic sulphides or chlorides; with oxygen the metals form oxides, and with acids they yield salts, such as carbonates, sulphates, and phosphates. All natural combinations of a metal with such mineralizing substances are called ores when the proportion of metal which they contain, after suitable mechanical preparation, is sufficiently large to admit of their being advantageously treated by the metallurgist. Although perhaps not strictly correct, any material obtained by mining that contains a workable proportion of a metal is often called an ore, even if the whole of the metal be present in the native state."

This definition, perhaps unconsciously so far as its writer was concerned, contrasts the point of view of the metallurgist with that of the miner. But it is a contrast of which we shall need to take cognizance. Thus a miner might extract a quantity of metalliferous minerals from the ground at a loss. He might sell them to a metallurgist at such a price that the latter could profitably treat them. They might thus not be ore for the miner, although ore for the metallurgist. If you saw a pile of magnetite at a blast-furnace being successfully treated you would call it ore, even though it had been bought at the bankrupt sale of some miner.

In W. H. Weed's translation of Richard Beck's 'Lehre von den Erzlagertacten,' under the title, 'The Nature of Ore Deposits,' New York, 1895, we find the following:

"In a mineralogical sense an ore is a metalliferous mineral or a mixture of such minerals. Practically, however, this definition of an ore must be qualified by the statement that only those minerals and mixtures of minerals are ores from which metals or metallic compounds may be produced on a commercial scale and at a profit. Two examples of equal mineralogical or petrographic value may differ materially, a basalt carrying enough magnetite to influence the magnetic needle, but yet containing less

than 10% iron, is far from being an iron ore. On the contrary, a vein with a silver content of only 0.5% is an ore deposit, since with this content it is commercially valuable. In the case of a gold deposit the amount sufficient to distinguish a gold ore from barren rock may be even less, for in California and Dakota gold ores with only 4 to 6 grains per ton of gold are exploited. Hence, it is the economic point of view that must always be borne in mind, the profit of working being subject to variation in the course of time. While nickel and cobalt were formerly nicknames for materials which were thrown upon mine dumps as useless, and were considered as a mere nuisance in silver mining, today the compounds of these metals and the associated minerals are in great demand as ores. To a certain degree a mineralized material may be an ore in one locality and yet not be an ore in another place, the cost of reduction depending on the proximity to lines of traffic and cheap freights. The science of ore deposits is, in other words, the study and consideration of the deposition, distribution, and origin of rock-bodies containing ores in such quantities that they may be extracted profitably by mining operations."

Heinrich Ries, in his 'Economic Geology of the United States,' New York, 1905, gives the following:

"The term 'ore deposits' is applied to concentrations of economically valuable metalliferous minerals found in the earth's crust, while under the term 'ore' are included those portions of the orebody of which the metallic minerals form a sufficiently large proportion to make their extraction profitable. A metalliferous mineral or rock might therefore not be an ore at the present day, but become so at a later date, because improved methods of treatment or other conditions rendered the extraction of its metallic contents profitable."

R. H. Stretch, in his hand-book on 'Prospecting, Locating, and Valuing Mines,' New York, 1903, writes in this way:

"An 'ore,' strictly speaking, is a single mineral which is a chemical compound of a useful metal and some other element or acid. In common usage, however, complex mixtures of pure minerals are considered as single ores: while free gold, native silver, and native copper, together with their accompanying gangue minerals, are also classed as ores. Among miners, whatever will pay to treat or ship and sell is considered ore, as also low-grade mineral which might be utilized by concentration or improved facilities; but there is an indefinite shading off into material containing traces of ore minerals but hopelessly unavailable, and this is not considered ore; neither are gold gravel or platinum sands called ore. To avoid misunderstanding it is best to distinguish between the 'ore' (meaning thereby the whole bulk of the available product) and the 'ore mineral' (usually very much smaller in quantity in all ores except those of iron, manganese, and some lead and zinc ores)."

Probably with search a few other definitions might be found, but without adding anything essentially new or important. I think that we must conclude that a distinction should be drawn between the

purely scientific use of the word and the technical. Not every metalliferous mineral is an ore even in the former sense. Many can be cited which it would be ridiculous to call by this name. Nor can a metalliferous mineral be called an ore unless at some time it has proved to be a practicable source of some metal. Once successfully used it establishes its standing and joins the group of the ores. This differs from Dana's definition that in an ore a metal should be a prominent constituent, since a species of amphibole might have 5 or 10% iron, iron being thus a prominent constituent, and yet not be an ore.

I suggest the following: In the scientific sense an 'ore' is a metalliferous mineral belonging to the group of those which have profitably yielded the metals to the miner or metallurgist. In its technical sense an ore is a metalliferous mineral or an aggregate of metalliferous minerals, more or less mixed with gangue, and capable of being, from the standpoint of the miner, won at a profit; or from the standpoint of the metallurgist, treated at a profit.

The test of yielding the metal or metals at a profit seems to me in the last analysis to be the only feasible one to employ. In a new enterprise, as we all know, it is customary to refer to the mineral in the ground as 'ore,' before it is proved to be such by profitable operation. If the enterprise should subsequently prove unsuccessful, it would only remain for those engaged in it to say that they thought they had ore, but that they had made a mistake. As soon as a shifting or variable standard is introduced, such as individual beliefs or expectations, such uncertain, changeable, and, on the whole, unsatisfactory conditions are developed that a sharp definition upon a secure and unmistakable basis becomes an impossibility. On the other hand, the test of profit certainly meets the requirement: "Use is the law of language."

A **silicon-calcium-aluminum** alloy is being introduced in this country by C. W. Leavitt & Co., of New York, the analysis being approximately silicon 47 to 57%, calcium 15 to 25, aluminum $2\frac{1}{2}$ to $6\frac{1}{2}$. The chief applications of the alloy are as an energetic deoxidizer and for securing a better desulphurization. It contains the two elements most useful for the deoxidation of a metal (silicon and aluminum), and also calcium, which is an energetic reagent. Added into the ladle it calms the steel and enables the tapping of sound ingots. The products of the reaction of this alloy are double silicates of calcium and aluminum, which have a low melting point, the slag rising to the surface of the steel. This alloy is said to give better results than aluminum alone, even when added in the ingot mold itself, because it forms an easily fusible slag which disengages from the steel. The alloy may be introduced either into the furnace a short time before tapping, or into the tap-hole during the tapping, or into the ingot mold instead of aluminum, or together with aluminum.

Only on steady load does a chimney give full efficiency, whereas fan-draft can be controlled to suit the requirements of the moment, and forced in case of emergency.

Estimation of iron and vanadium in the presence of each other may be made as follows: if a solution containing both Fe and V be reduced by SO_2 the V is reduced to V_2O_4 , Fe to FeO. Titration with permanganate oxidizes the V to V_2O_5 , FeO to Fe_2O_3 . If the same solution be passed through a reductor and received in a solution of $\text{Fe}_2(\text{SO}_4)_3$ the V is reduced to V_2O_2 , the Fe being again brought to FeO. The reducing power of the V_2O_2 is transferred to the Fe_2O_3 of the receiving solution, and now titration with permanganate shows the increased reduction due to V_2O_2 in the latter case, against that due to V_2O_4 in the former. This difference can be calculated to V. The other portion of the permanganate used has been destroyed by the FeO, which may be calculated accordingly.

The village of Kilmore, in County Galway, Ireland, has been engulfed by the great sliding bog of Kilmore, most of the cottages having been covered up to the roofs. About one seventh of Ireland is covered with bogs, that of Allen alone comprising 370 square miles, with an average depth of 25 feet. The method by which a bog invades its neighborhood is singular. Originally it will have been a lake, around the shores of which vegetation has grown outward, both at the surface and on the bottom. Eventually the vegetation on the surface forms a strongly matted layer, beneath which lie the muddy waters of the lake. Heavy rains then augment this intermediate watery layer until the centre swells up, the skin of vegetation bursts, and a deluge of black mud pours out into the surrounding country.

In determining the calorific value of peat it is better to make direct determinations in a calorimeter than to rely on Dulong's formula, as determinations by his formula invariably gave results 6 to 10% too low.

USES OF ALUMINUM.

By J. T. W. ECHEVARRI.

*Aluminum is obtained electrolytically from bauxite, cryolite being used as a flux. Most of the metal turned out today carries close upon 99½% of aluminum, while metal with as little as 0.4 to 0.3% impurity is obtainable for special purposes. The impurities commonly found in aluminum are iron, silicon, and sodium. Silicon renders aluminum brittle if present in large quantities. It also impairs the resistance to corrosion peculiar to pure aluminum. The thin yellow coating which forms on the inside of aluminum cooking utensils is largely composed of silica. The percentage of silicon should in no case exceed 0.4 to 0.5%, although the metal as used in iron and steel works may contain double this amount.

Iron occurs in high-grade aluminum to the extent of about 0.2 to 0.3%, and while impairing the ductility in the same way as silicon, the tensile strength is somewhat improved by its presence in small quantities. Iron does not appear to affect the electric conductivity of aluminum to the same extent as silicon, but has a bad influence on its non-corroding properties. Sodium is the most injurious impurity, as the resistance to corrosion is seriously lowered by even small quantities of this metal. Improved methods of manufacture have, however, eliminated all but the minutest traces of this element, till today more than 0.006% sodium is rarely found.

The pure aluminum of commerce is a silver white metal, with a melting point of 657° C., and a specific gravity ranging from 2.56 to 2.72, according to its method of treatment. Copper having a specific gravity of about 8.8, zinc about 6.9, and tin about 7.3, it follows that aluminum is about 3.3 times as light as copper, 2.5 times as light as zinc, and 2.7 times as light as tin. The heat-conductivity of aluminum is high, being second only to copper among the common metals. Its electrical conductivity is also high, being from 60 to 62% of that of pure electrolytic copper; it having, like copper, a somewhat lower resistance when soft than when hard drawn.

The strength of pure aluminum depends to a large extent on its methods of treatment, but the following table gives average figures for the metal in various forms in pounds per square inch:

	Ultimate tensile strength.	Yield point.	Elonga- tion, %.	Modulus of elasticity.
Sand castings	10,000	5,000	25	
Chill castings	10,500	5,000	35	
Rolled bars	14,000	10,000	35	
Rolled sheet	18,000	16,000	6	
Drawn section	17,500	16,000	20	
Hard-drawn wire . . .	30,000	26,000	25	9,000,000
Soft-drawn wire . . .	14,000	8,000	30	10,000,000

Aluminum may be melted in ordinary plumbago crucibles, but where quantities are to be melted a reverberatory furnace is generally used. It should not be heated above 725° C., to avoid 'burning'. At that temperature aluminum readily oxidizes. Sheet can be re-melted by submerging in the molten metal, the loss being only from 2 to 3%, which is much

lower than in the case of brass and similar metals.

Aluminum can be cast in either sand or chill molds, the latter method being generally employed where a good finish is required. Aluminum cast in polished steel molds has a finish equal to the best machined surface. For rolling it is cast into large slabs or blocks, which are afterward broken down hot, the intermediate and finishing stages being done cold, the amount of annealing being governed by the temper and finish required. Where an extra finish is required, as for photographic and lithographic work, great care is necessary in preparing the finished plate. Where a dead or roughened surface is required on the finished sheets, as for painting, decorating, and varnishing, they are dipped in a 10% solution of caustic soda for a few minutes, and afterward washed in clean running water. To obtain a satin finish, as required for printing, the sheets are passed under a rapidly revolving scratch-brush.

Aluminum can be easily drawn into sections, tubes, and wires, the same methods being employed as for copper. The billet is first rolled down hot to a convenient size, and afterward reduced to the correct section on the draw-bench, cold fat being used as a lubricant. For drawing down to the finer gauges in wire-drawing machines, paraffin is employed as a lubricant. The amount of annealing during the process depends upon the temper required. Wires from ¾ in. down to 0.018 in. diam. can be drawn in this manner, these being used for practically all purposes where copper, brass, or german silver wire is used. Sections, rods, and tubes can be made by forcing the solid metal, at a temperature of about 80° C., by hydraulic pressure, through suitable dies. Soft aluminum sheets can be spun, stamped, or pressed into various shapes, cocoa-nut oil or other lubricant being used. For turning, a sharp-edged tool with a good clearance should be used, and the work run at high speed, combined with a slow traverse, plenty of lubricant in the shape of soap and water or paraffin being applied. For drilling holes a diamond or nose-drill, with ample clearance, should be employed, a twist-drill being liable to 'seize'. Screw-threads can be cut with an ordinary tap, using a little light oil as a lubricant.

Aluminum can be soldered by means of various solders now on the market, but as soldered joints are all subject to electrolytic action in the presence of moisture, they are only suitable when protected from damp air. Welded joints, being entirely of aluminum, do not suffer under these conditions, and this method is being more extensively adopted, now that satisfactory welded joints can be made by means of portable oxy-acetylene blow-pipe equipments. It had long been recognized that this was the most hopeful direction in which to experiment, because such joints, containing as they do nothing but aluminum, would be as free from electrolytic action as the metal itself, but the difficulty met was in getting rid of the film of oxide, which prevented the two surfaces uniting properly. In the case of butt-welding of small rods and wires, this difficulty can be overcome by applying end pressure at the moment of fusion to drive out the film of oxide, but in the case of sheets and

*Abstract from paper read before the Institute of Metals, London.

plates the method is not practicable. Several fluxes have been put on the market capable of dissolving the film of oxide and permitting the metal to flow together with perfect ease. Another method of welding aluminum sheeting, which would repay further investigation, is the electric system, by so-called spot-welders.

Aluminum is used in iron and steel works for removing the oxygen from the oxides of iron, and other substances, with which it comes in contact, the heat generated by this reaction being so great that it may also be of service in raising the temperature of large bodies of iron. The efficacy of small quantities of aluminum in preventing 'porosity' is also marked. Porosity is due to the partial disengagement of gases absorbed during melting which are imprisoned as the metal cools. Aluminum has the property of combining with these gases to produce a slag. It frequently happens that a casting requires two 'blows' of the cupola. In this case the difficulty of keeping the first tapping hot while the second charge is running down may be overcome by adding from time to time small quantities of aluminum to the metal in the ladle. For the purpose described, the metal may be employed in various forms. An alloy known as ferro-aluminum, consisting of about 90% iron and 10% aluminum, is employed by many iron and steel founders. The use of ferro-aluminum has, however, been largely superseded by that of the pure metal. Some steel makers use aluminum in a form known as 'granulated', varying in size of grain from that of rice down to that of sifted sugar.

A further application of this principle has been made in the 'thermit' welding process invented by Goldschmitt, where the heat of combustion of aluminum and oxygen is made use of to raise the temperature of iron and steel castings to the welding point. For welding tramway-rails and the like, the two parts to be joined, after being carefully cleaned, are firmly fixed, leaving about $\frac{3}{4}$ in. between them. A sand mold is then formed round the joint, in such a form that the section at the joint after the molten metal has been run in would be somewhat larger than the normal section of the rail. This mold is then heated by means of a powerful blow-lamp to a dull red heat, and the molten iron produced by the 'thermit' reaction is then run in from the funnel-shaped crucible in which the reaction has taken place. After the joint has cooled the mold is removed. Joints made in this manner have been subjected to both tensile and bending tests, and are found to be fully equal to the rest of the rail.

For castings, it is found of advantage to alloy the metal with copper, zinc, or nickel, which increases the strength and makes it easier to work, without materially increasing the weight. Standard light-weight alloys with the following characteristics are regularly made: (a) Specific gravity, 2.7; tensile strength, 14,000 to 18,000 lb. per square inch; elongation, 5 to 10%. This alloy makes castings which will afterward rivet or take a set, so that it is an admirable substitute for soft brass. Being soft and tough, it can be easily forged, stamped, or drawn, such working increasing its tensile strength up to as much

as 36,000 lb. per square inch. (b) Specific gravity, 2.9; tensile strength, 18,000 to 22,000 lb. per square inch; elongation, 2 to 5%. This alloy is designed to give specially clean castings, easily machined, able to take and retain a high polish. (c) Specific gravity, 3.1; tensile strength, 22,000 to 26,000 lb. per square inch; elongation, 2 to 4%. This is also a casting alloy, but considerably harder than the foregoing, and makes a rigid strong casting which will take and hold a set-pin. It is a splendid metal for machining, and takes and retains a fine finish. The yield point under compression is also high, being about equal to its ultimate breaking strength in tension.

When rolled into sheet, the uses of aluminum are too numerous to mention, as the light metal is every day coming into stronger competition with older metals. Aluminum, being, next to gold, the most malleable of all the metals, it can be spun, stamped, pressed, or worked under the hammer into every imaginable shape, and its uses in connection with the manufacture of articles of everyday use are unlimited. Another point in favor of aluminum is that the metal takes and retains a high polish. It has for some years past been used almost exclusively in place of silvered copper for parabolic reflectors in motor headlights.

Wall 'paper' and ceiling-panels made of thin embossed sheet is a refinement of modern art, the use of which is likely to become more general now that the price has been reduced, as such a covering is not only fire-proof, but can be washed, and is more durable than ordinary wall-paper. Aluminum sheets of special finish have for many years been largely used for lithographic purposes, and are gradually but surely replacing lithographic stones and zinc plates. Aluminum sheets are also largely used for the panels of car and carriage bodies, as well as for tram-cars and electric trains. The saving in dead weight is of considerable importance, especially in the case of electrically driven trains, subject to frequent stops and starts, as the power required for acceleration is in direct proportion to the weight to be moved.

In the early days of the aluminum industry, sheets composed of copper alloys were used to some extent in shipbuilding. It has, however, been demonstrated that pure aluminum of the best quality should be used, and there is little doubt that naval constructors will find pure aluminum sheets, channels, moldings, rivets, and so forth, of great assistance in partitions, ceilings, deck and chart-houses, and similar portions of large ships above the water-line, where reduction of top-weight is of importance in connection with the stability of the vessel.

The advantages of aluminum for culinary purposes are universally known; its durability and absolutely non-poisonous qualities being among its chief recommendations. Aluminum powder is being used to an increasing extent in the manufacture of metallic paints and varnishes, its non-tarnishing qualities making it particularly suitable. Aluminum paint is used extensively for protecting iron and wood-work, rendering the latter to a certain extent fireproof if a thick coating be applied. For printing purposes alu-

minum paint and leaf is also supplanting silver, as it is found to adhere better to the paper. Thin aluminum foil is also used largely for packing, in place of lead or tin, its non-poisonous properties making it particularly desirable. Large quantities of specially pure aluminum tubes are used for various purposes in acid work, under which condition the pure metal remains practically unaffected. In order to demonstrate the usefulness of aluminum tubes for steam coils, some tests were made at Milton some time ago, with the following results:

Length of tube, in.	Gauge.	Outside diameter, in.	Tested to lb. per sq. in.	Remarks.
12	10	3 1/4	1200	Expanded to 1/2 in. in middle, but returned to original size on release of pressure.
12	12	2 11/16	1200	Ditto (barely 1/32 in.).
12	14	2	1200	As above, with rather less expansion.
12	14	1 1/8	1200	Perfect. Would probably stand considerably more.
12	19	1 1/8	1200	Ditto.

All the above were afterward tested at 100 lb. per square inch for half-an-hour, with the exception of the second, which was under the steam-test for 12 hours without apparent injury. This tube was, after the steam test, subjected to a second test of 1200 lb. hydraulic pressure, and showed no signs of fracture. The sample piece of tubing exhibited has been cut from a 12-ft. length which was coupled to an iron steam-supply system, by means of iron clamps, and after being in use for five or six years reveals no sign of deterioration. There also appears to be a field for aluminum for galvanizing purposes, by introducing small quantities of the metal into the bath, rendering it more fluid, enabling a larger surface to be galvanized with a given quantity of zinc, and producing a brighter finish than is otherwise obtainable. As a conductor of electricity, aluminum has a large field of usefulness. The saving that can be effected by using aluminum in place of copper for overhead conductors is so large that in countries where long overhead transmission lines are in vogue the lighter metal practically reigns supreme. In England there has not been up to the present the same opportunity for long-distance bare overhead transmission lines, but during the past few years many short-distance aluminum lines have been erected for lighting and power. Aluminum as used for electrical purposes has a conductivity equal to about 61% of that of pure electrolytic copper, so that to obtain the same conductivity it is necessary to increase the sectional area by 64%, corresponding to an increase in diameter of 28% for a round conductor. Copper being 3.3 times heavier than aluminum, the somewhat larger aluminum conductor will weigh less than half of the equivalent copper conductor, the larger cooling surface of the aluminum conductor being a further factor in its favor. For small diameter wires, as used for making up into cable, the usual butt-welded joint is made either in the flame of a blow-lamp, or by means of electric welders, as used for copper. For bare-stranded cables the usual method is to weld the two ends together by pouring molten aluminum into

a cigar-shaped mold, previously clamped around the joint, but where high tensile strength is required a mechanical joint may be used, so designed as to give a wedging action when pulling tight, in order to ensure good electrical contact. The tensile strength of hard-drawn aluminum wire is equal to about half that of copper wire of equal section, but allowing for the increased size of an aluminum conductor to obtain the same conductivity as for copper, this figure is raised to about 75%, the difference being more than compensated by the decreased weight of the aluminum cable.

Tungsten may be separated from silica by the following method, proposed by Bourion: A weighed amount of the sample is placed in a porcelain boat, which is inserted in a combustion tube, and the boat is strongly heated in a current of Cl, containing a little S₂Cl₃. It is volatilized as chloride or oxychloride, which is caught in water placed in the receiver. SiO₂ remains in the boat, and may be weighed after washing and igniting. The contents of the receiver, together with ammoniacal rinsings from the tube, are evaporated with HNO₃, H₂SO₄ expelled by heating, and after treatment with NH₄NO₃ the WO₃ is ignited and weighed. Defacqz recommends a similar process. The material is treated in a boat within a combustion tube, first in an atmosphere of H to reduce the W, afterward in a current of Cl to volatilize the W and leave the SiO₂.

What are designated as 'low-resistance pyrometers' have, during the last few years, come widely into use. They are the logical outcome of the discovery that, while thermo-couples of certain alloys of base metals will not maintain their e.m.f., and, in some cases, not even withstand the physical and chemical assault of the very high heats that the platinum-rhodium couples will meet, they will, nevertheless, withstand the more moderate heats when such base metal couples are constructed with elements of large cross-section.

The melting point of iron which has been commonly accepted is nearly 100° C. too high for the melting point of pure iron, as shown by figures given by H. Carpenter in *Metallurgie*, November 22. He gives as the melting point of pure iron 1505° as measured by the Le Chatelier pyrometer and 1491 to 1519° for the optical scale. The freezing point is independent of the gas in contact with the metal, a fact difficult to explain when we know that oxide of iron is quite readily dissolved by the molten iron.

Willemite as a commercially important mineral of zinc ores is mined at Tres Hermanas in southern New Mexico. The mineral forms dense masses consisting of slender hexagonal prisms, and is associated with calcite, a little smithsonite, and calamine, as well as hydro-zincite. The occurrence is in the oxidized portion of a contact metamorphic deposit in limestone at a contact with quartz-porphyry. A number of car-loads of this mineral were shipped in 1905. The mineral was identified by analysis.—W. LINDGREN.

MINING AND METALLURGICAL PATENTS.

DOUBLE-ACTING BAND-BRAKE.—No. 910,435. Don N. Thompson, Owego, New York.

In a double acting band brake, a rod the two ends of which have threads and key slots cut therein, two sliding blocks adjustably secured on said rod, stop nuts threaded on the opposite ends of the rod for adjusting said sliding blocks, an applying lever one end of which is pivotally secured to one end of said sliding blocks, a sleeve pivotally secured to the opposite sliding block, a forked rod one end of which is threaded in said sleeve, the opposite end being secured to the applying lever, a band adapted to pass around a drum on one end of said band being secured to the under side of the inner end of one of the sliding blocks, the opposite end being secured to the under side of the inner end of the opposite sliding block, and nuts for securing the rod to the supports.

HOISTING APPARATUS.—No. 913,020. Frederick W. Lovell, Cleveland, Ohio.

Hoisting apparatus comprising a bridge, trolley carriage, and an automatic bucket having a holding rope and a hoisting and trolleying rope, and means for automatically taking up slack in the holding rope, the operation of said means being independent of the lateral trolleying movement of the bucket.

SURVEYOR'S TARGET.—No. 913,069. Grant T. Stephenson, Wells, Michigan.

A surveyor's target comprising an inner plate adapted to be fixed to a staff, an outer plate movable in guides over the face of the inner plate and of approximately the same size, members extending laterally from the respective plates and having registering bores the bore of the movable plate member being screw threaded and that of the next member unthreaded, a fine threaded micrometer screw having an unthreaded portion rotatable in the bore of the fixed mem

ber with its threaded portion engaging the screw threaded bore of the movable plate member and means for holding said screw against longitudinal movement.

MEANS FOR EXPANDING COMPRESSED AIR.—No. 912,647. Robert S. Cates, Kingman, Kansas.

In refrigerating apparatus, the combination of a chamber having its lower portion contracted and its upper portion enlarged and adapted to receive a liquid refrigerant, an air expansion pipe located in the contracted portion of the chamber and immersed in the liquid refrigerant contained therein and open at its top and bottom, means for supplying compressed air to the lower portion of the air expansion pipe to cause the air and liquid to pass through said air expansion pipe in alternate separated portions, and a partition arranged in the upper enlarged portion of the said chamber to effect separation of the air when expanded from the refrigerant.

TUNNEL-BORING DEVICE.—No. 912,575. Reginald H. Keays, New York.

In a structure of the class described, the combination with permanently-positioned tunnel-members of a shield; a jack-frame independent thereof and supported by said tunnel-members; and forcing devices mounted in said jack-frame and interposed between said shield and said jack frame.

METALLURGICAL PROCESS.—No. 913,535. George Moore, New York.

The process of separating metals from their ores, consist ing in volatilizing salts of the metal in a suitable vessel, forcing steam upwardly through the subjected ores, and con densing the impregnated steam.

Filter Plants at Pachuca.

Written for the MINING AND SCIENTIFIC PRESS
By C. G. PATTERSON.

The Loreto plant, at Pachuca, Mexico, has 104 Butters filter-leaves, and uses an 8-in. Butters pump. The plant was designed in July, 1907; it was completed and started in operation the middle of January, 1908. The plant was designed for two units, or boxes, each box to contain 104 filter-frames with a rated capacity of 200 tons of dry slime for each unit. Shortly after the first box was put in operation, 4 tube-mills were added to the crushing plant, which gave a finer product and a greatly increased tonnage. The following is a copy from the filter log-book of February 12, thir-

Butters Filter in Loreto Mill, at Pachuca.

teen months after the plant was started, and is a fair average of regular performance.

Sizing-test of pulp, plus 150 mesh $3\frac{1}{2}\%$, plus 200 mesh $4\frac{1}{10}\%$, minus 200 mesh 92. The day's run consisted of 6 charges from the treatment-tanks, as follows:

Tank No.	Charge No.	Sp. gr.	Dry tons filtered.
23	187	1.41	61.73
30	189	1.41	50.89
28	191	1.42	68.90
27	192	1.37	50.56
10	193	1.41	59.49
3	195	1.45	61.62

Total tonnage, 24 hr. 353.17

The tonnage was handled in 16 charges, making the average time of each cycle 1 hr. 30 min. In 14 of the cycles 100 filter-leaves were in use, and in two cycles 99 leaves. The average thickness of cake formed was 1 in., and the time of forming these was 30 min. in each cycle. Of course, by crowding the filter so much beyond its rated capacity, there was only time for 15 min. water-wash, which is not sufficient to make a complete recovery of the dissolved gold. With this rapid work a saving of 40c. per ton net more than would be possible without the filter was accomplished. The power consumed by the 8-in. Butters pump, vacuum pump, and agitator in the stock pulp-tank was 675 hp.-hr., or 1.9 hp.-hr. per ton of dry slime treated. The leaves are in good condition. An addition of 200 filter-leaves is being made, 100 for the second unit of the Loreto plant and 100 for the second unit of the Guerrero plant.

The Guerrero plant is at Real del Monte, about 9 miles from Pachuca. The plant was designed in August 1907, and was completed and put in use November 1908. It has 96 filter-leaves and is on the semi-gravity system, the box filling by gravity through 10-in. pipe-lines, and the excesses returned through the same pipes by an 8-in. Butters pump. Their log-book of January 30 presents a good average of the

work done. Specific gravity of pulp 1.3, 90% passing a 200-mesh screen. The cake formed is 1 in. in 30 min. The complete cycle of operations takes 1 hr., 30 min., time of wash 30 to 35 min. Owing to the semi-gravity system, the time of transfer is shorter than in the pumping system. This plant was also designed for a second unit, it only being necessary to add the extra box and leaves. At present it is a good example of simplicity and efficiency. Both plants, when doubled, will be operated with the same amount of labor as at present. It may be noted that the 600-ton plant of the Goldfield Consolidated Co. requires no more labor than the 70-ton plant at the Combination mill.

Commercial Paragraphs.

E. C. GRICE and E. M. BUSS have established a metallurgical laboratory at Boise, Idaho, having organized the Boise Laboratories Company.

THE AMERICAN DRAFTING FURNITURE Co., Rochester, New York, announces that its new loose leaf catalogue will be ready for distribution soon.

THE CUTLER-HAMMER MFG. Co., Milwaukee, announces the opening of a district office in Cleveland, Ohio—1108 Schofield Bdg.—in charge of C. J. Kruse.

THE BYRON JACKSON IRON WORKS, West Berkeley, Cal., has recently furnished a two-stage deep well turbine pump for the Illinois Eastern Hospital for the Insane at Kankakee, Illinois.

THE D. D. DEMAREST Co., San Francisco, advises that it has recently received a 'repeat' order for Pacific Lubricating Stopcocks from the management of the North Star mine at Grass Valley.

THE A. S. CAMERON STEAM PUMP WORKS, New York, has lately published a wall map showing the route and profile of the Panama Canal. A smaller scale map shows the distances from the world's principal ports to the termini of the canal.

THE AMERICAN GRÖNDAL KJELLIN Co., New York, announces that a testing plant for the concentration of iron ores according to the Gröndal system has been opened at Sheridan, Pennsylvania, where ores will be received and tested free of charge.

THE KROGH PUMP Co., San Francisco, advises us that it has recently sold two 4-stage turbine pumps to the city of Oakland for a new high-pressure fire system. Also a large dredging pump has lately been shipped to the city of Seattle for use in sewer construction.

THE HENDRIE & BOLTHOFF MFG. & SUP. Co., Denver, in its March letter announces the fact that it has secured the exclusive manufacture and sale of the Bunker Hill screen. This is a wet screening device, developed and perfected in the mill of the Bunker Hill & Sullivan Mining Co. at Wardner, Idaho. The screen has been tested and is now ready for the market.

THE VULCAN IRON WORKS, Seattle, Washington, has under construction new buildings for a complete plant. The principal building will be a supply and jobbing house 100 by 270 ft., seven stories high. Seven other buildings will bring the total floor space up to over 250,000 sq. ft. Catalogues and literature descriptive of steel-concrete buildings, modern foundry equipment, machine shop tools, and the like will be welcomed by the company.

Catalogues Received.

THE ORE DRESSING MACHINERY Co., New York, is distributing a pamphlet describing the Hennig concentrating table.

CHALMERS & WILLIAMS, Chicago, in their Catalogue No. 1, Section L, describe the Kennedy gyratory crusher and discuss its advantages.

THE WELLMAN-SEEVER-MORGAN Co., Cleveland, Ohio, has just issued a new bucket circular describing with photographs, drawings, and printed matter its extensive line of buckets for handling ore, coal, crushed stone, cinders, and so forth.

EDITORIAL.

A BILL for a Bureau of Mines has been introduced into the House of Representatives by Mr. Coudery of Missouri. It is doubtful whether it will come to vote at the present special session of Congress.

TWELVE States and Territories have appropriated sums ranging from \$15,000 to \$400,000 each for exhibits at the Alaska-Yukon-Pacific Exposition at Seattle. Six other States have bills pending before their legislatures, providing sums of money for the same purpose. A fine mineral display is promised.

CONTINGENT FEES formed the subject of discussion at a recent meeting of the New York section of the Mining and Metallurgical Society of America. We publish the opinions expressed on that occasion, believing that the matter is of general professional interest. Whatever the views held or expressed by mining engineers, it is well to clarify our conceptions of right and wrong in matters that touch the fundamentals of professional honor. We shall not all agree upon any hard and fast rule, but we can assert the principles that guide right conduct and thus, by creating a healthy public opinion, stiffen the moral backbone of the mining profession.

RESIDENCE in a foreign country modifies the point of view, by enlarging it; therefore, when an American mining engineer returns from South Africa, he is able to make interesting comment on technical practices in his home country. In this issue we publish such comment from Mr. T. Lane Carter, an American from south of Mason & Dixon's line who has lived in the Transvaal for ten years. For several years he acted as the Johannesburg correspondent of this journal, while in charge of important mines in that region. He has recently visited the chief mining centres of America and, at our request, he has contributed criticisms which are suggestive.

FROM GOLDFIELD comes the gratifying news that Mr. J. H. Mackenzie and Mr. E. Hampton have opened up a new, large, and rich orebody in the Combination ground of the Goldfield Consolidated Mines Company. This orebody is in territory that is virgin, with a chance of further development in an area fully 700 feet long. The ore has been cut on the fourth, fifth, and sixth levels, and within 14 days has yielded \$300,000 from material broken in exploratory workings. We are informed that the indicated ore, that is, ore likely to be developed, is estimated at \$4,000,000. The lode has a maximum width of 30 feet, and contains a streak assaying \$30 per pound.

so that an average of \$100 per ton is not surprising. But it is surprising that the information should be given weeks after the event, at the close of a period during which bear tips have been circulated. Should the discovery prove to be all that is expected there will be a rise in the quotations, enabling those who recognize the inflated capitalization of Goldfield Consolidated to sell to others more speculatively inclined. More money is lost in over-capitalized and over-estimated rich mines than in worthless holes-in-the-ground. The Consolidated of Goldfield is a great mine and we hope it may, under its experienced superintendency, continue to develop. But until the directorate publishes proper monthly and annual reports, acting like trustees rather than privileged speculators, this splendid enterprise will remain only a colossal gamble.

COPPER will soon be produced on a large scale by the Braden Copper Company in Chile. The mine was developed under the guidance of Mr. William Braden, and subsequently examined by Mr. Allen H. Rogers at the instance of Mr. A. C. Beatty. As a result of the favorable report which Mr. Rogers returned, coupled with demonstrations of the low price at which the ore can be mined and smelted, the Guggenheims have issued \$4,500,000 in bonds to finance the property, the bonds being promptly over-subscribed. A narrow-gauge railroad will be built from Rancagua on the National line, in the Province of O'Higgins, to the mine, a distance of 45 miles. It is considered certain that copper from the Braden mine can be delivered at New York or European ports for less than 8 cents per pound.

A CORRESPONDENT asks what is a mineralizer? The dictionaries gravely inform us that it is a substance that mineralizes, or converts a metal into a mineral or ore. The term has been employed usually with an eye upon economic considerations, although geologists also speak of the substances promoting the formation of minerals in a magma as mineralizers. Such use of the word seems open to objection. The popular conception must rule, for once a term has passed into common speech its employment with any other meaning only defeats the ends of accuracy. Mineralizer has come to signify a chemical agent resulting in alterations of rocks with the introduction of metals or metallic compounds. Hence its tendency is, as the lexicographers indicate, to produce what will become an ore if the metallic content be high enough to admit of economic extraction. The word has regard to the function rather than the substance: any agent serving to effect alterations and new combinations, leading to the formation of metalliferous deposits, is a mineralizer because of the office it has performed. Limited to that meaning, which is undoubtedly the idea that the expression conveys to the average man, no uncertainty can follow its use.

VIEWS expressed by the chairman of a London trust company have emphasized the relative lowering of British credit as measured by the depre-

ciation of capital invested in British territory. Consols compare favorably with French or German national bonds, but they have always done so; American railroad bonds offer higher interest than British railway debentures, but this also is nothing new; in Japan, Mexico, and Brazil a 5 per cent return is available with moderate safety; and yet in the past these allurements have not tempted the conservative investor to neglect British securities offering a smaller income. Now apparently they compete successfully, so that British securities suffer. Hence it is argued that British credit has fallen. We do not see it that way; to us it appears more reasonable to impute the change of financial sentiment to another and more pleasing cause; namely, the improved conditions in foreign countries and in America. By reason of the investment of English capital and because of English influence in the development of industrial security under improved government, such countries as Japan and Mexico have ceased to be rated among the semi-civilized; on the contrary, financiers deem them no more likely to repudiate their debts than Great Britain herself. In America, despite the financial legerdemain of a few predatory individuals, the general tendency has been toward affording better safeguards for the investing public, therefore the higher rate of interest is now more attractive than formerly. But even in America the rate of interest obtainable on gilt-edged securities is steadily declining; if a comparison were made between the rates obtainable on the best bonds twenty years ago and today it would be seen that the earning power of money has declined, as in England.

Magmatic Segregation.

Magmatic differentiation is a subject that will not down any more than Banquo's ghost. It is really an ancient theory; perhaps it antedates the science of geology. The old notions return with rhythmic persistence, because truth abides in each of them. No one theory of ore-formation can cover all cases. Even the conception of intrusive veins has been revived for us with the endorsement of Mr. J. E. Spurr; he assures us that many quartz lodes are only dikes of the extremely acid residuum of a progressively differentiating magma. Mr. F. L. Garrison discusses this interesting subject elsewhere in this issue, reviewing it from the standpoint of basic rather than acid concentrations. Gravitational segregation finds ready acceptance, but both central and peripheral enrichments are also known. Nature refuses to construct ceaselessly after the same pattern. Her laws are many, and admit of changing styles. Hence convection currents and Soré's principle are both called upon to account for the phenomena of magmas with a core of basic, relatively metalliferous, minerals, so common in the case of pyroxenites, and of those with enriched borders, of which the norites present frequent examples. In the vast stretches of time which Nature has for working out her processes the application of mathematic determination of feasibility must not be pressed too far, our data being based on facts observed upon too small a scale. It is stag-

gering to think of either convection currents, or the comparatively limited influence excited by changes in the diffusion-pressure resulting from inequality of temperature, operating through masses of molten rock miles in diameter. But if not these, what forces could have produced such differentiations? That they exist cannot be denied, and that the crystals were not secondary the microscope has proved. But the mere relative enrichment of certain parts of magmas is a different matter from the formation of orebodies by these processes. We believe that such concentrations are not found, unless we admit the classic titaniferous iron deposit of Taberg, Sweden. But, that primary weak concentrations of this character must facilitate further concentration into lodes and masses by hydro-chemical means seems undoubted, and Mr. Garrison has done a distinct service in accentuating that point.

The question of occluded gases in rocks is of equal moment. These possess an interest of the highest order for the economic geologist. They assist in solvency; their elimination promotes crystallization; they probably perform other functions of which we know little. But we may be sure that no gas can be absorbed into a magma with the constituents of which it can chemically react. Hence oxygen is never found. What seems remarkable is the absence of nitrogen, a gas which presents so many difficulties in fixation. Between the power of condensation of gases by a molten magma and the facility with which the magmas differentiate there apparently exists a close connection. This question seems fairly raised by Mr. Garrison's paper and should provoke much helpful comment.

Copper Tendencies.

Copper is the everlasting enigma. For decades it has been the delight of market-jugglers, and the confusion of speculative wise-acres. That copper has been on the free list and consequently subject to the tidal movements of economic law may in part account for the phenomenon. The public looks ever for the cloven hoof; it believes less in natural law than in the mysterious market-influences of sinister operators in Wall Street. The public has persisted in regarding the Copper Producers' Association as a Trust in disguise, attributing the low price of copper to the malicious designs of that organization. In point of fact no combination for regulating production and prices exists. Such a combination would undoubtedly be effected were it possible, but there are too many powerful producers independent of the Amalgamated to permit that concern, as the natural nucleus, to gather the others into a solid concretion. The independents can make copper more cheaply than the Amalgamated. There's the rub. To depress prices would injure the Amalgamated more than its rivals. In fact the apparent influence at the moment of the lesser lights in the copper firmament would be to reduce prices in order to crowd out the Montana mines and keep a bona fide market for their own output. It costs money to store copper; it is said that syndicates have retired more than nine million dollars' worth within the last few months, deeming

it preferable to lock up money for a period in this unremunerative manner than to incur the costlier damage following the closure of great mines and works. How long such a strain can be endured depends upon the abundance of money at low rates. Financial conditions just now peculiarly favor the policy to which the copper producers have been obliged to resort. Money goes begging in Paris at one per cent, and it is considered that French capital is probably carrying the present excess of copper production. Meanwhile the producers are lowering prices to stimulate a demand from actual consumers. It cannot be truthfully said that the depression in the copper market is sympathetic with the cut in steel prices, for copper had been selling proportionally too low for the ruling rates in iron and steel.

Depression is usual in the winter and early spring months. In the last eight years the lowest level in the price of copper occurred once in December, three times in January, twice in February, and once in March. Moreover the current market price is not as exceptional as many are inclined to think. The average rate in 1902 was 11.52 cents per pound, which is below present quotations, and the average of the three years 1902-4 inclusive, was 11.92 cents. It is undoubtedly true, however, that costs of living and of supplies were less in those years, which would admit of meeting successfully a more adverse market. Many mines which were highly profitable at one epoch, under one set of economic conditions, find difficulty in maintaining themselves against the counter-currents of an altering industrial era. Hence it is not surprising to see the copper magnates reaching out for great deposits of low-grade ore which can be worked more cheaply. There probably has been no period, save during the months of insane speculation at the zenith of the late boom, when copper properties were in greater demand than at this very time of low prices and over-production. A good mine, that will admit of producing refined copper laid down at tide-water for 8 cents, will not need to look long for a purchaser. But the day of the 12-cent copper mine is passing. The narrow vein, the deep mine, are looked upon with doubt. The copper miner today wants orebodies so large that he can work them, after the manner of iron mines, with steam-shovel, or by the caving system. The only thing that can recommend a small vein today is the presence of precious metals in the ore sufficient to render the copper in large part a by-product. Mines of the type of the Utah Copper, the Boston Consolidated, the Nevada Consolidated, the Miami, the Ray Consolidated, which it is claimed can deliver electrolytic copper in New York at a cost of 8 cents or less, and of the Cerro de Paseo in Peru, which is credited with delivering it at 7, are the sort that the so-called trust-magnates are reaching after. The result will likely be the development of a dominant group—a Trust. It seems inevitable. Only those lesser operators who can make copper as cheaply, or more so, can survive. The engineer who estimates the future of a mine on a cost-basis higher than 9 cents per pound is clearly in danger of misleading his client.

BY THE WAY.

On the occasion of its 21st birthday, *The Financial Times*, London, published a retrospect. Among the articles was one by Mr. W. R. Lawson, from which we abstract as follows:

When one begins to think of those who are dead and gone, dozens of City ghosts arise out of the forgotten past. But before conjuring them up, it will be necessary to decide how to classify them. The ghost of Baron Grant, for instance, would hardly be welcome among past Governors of the Bank of England. Neither, perhaps, would it feel at home among the disembodied Duchesses who once paid court to the Baron in Lombard street. In order to avoid confusion among the spirits to be conjured up, it may be advisable to borrow distinguishing terms from the dramatic profession. Instead of using invidious names, let us regard finance as being of two kinds—legitimate and illegitimate.

When the period began Baron Grant was still among us, but his sun had set. He had withdrawn from the stately offices at the corner of Lombard street and Nicholas lane to humbler, but still handsome, quarters in Cannon street, near the railway station. There, in 1886, I had my first and only interview with him. He gave one the impression of being a constitutionally and incurably sanguine person.

But, if he failed himself, he blazed a path for those who followed him. His successors—Whitaker Wright, Hooley, and the rest—had a double advantage over him. They had machinery and methods ready to hand which he had helped to create. At the same time, they had a much more credulous public to operate on. Joint stock securities were much more familiar, as well as much more popular, in 1895 than they had been twenty years sooner.

In its later stages illegitimate finance was taken up by a new kind of trust companies, formed ostensibly for other purposes. The Trustees' Executors' and Securities Insurance Corporation was, according to its original charter, to administer private estates, but, almost from the outset, it launched into promoting. It soon had a crowd of imitators, and in the years 1887 to 1889 more speculative issues were made than in the preceding ten years. The collapse of 1890 brought them to a sudden end, and in the hard years which followed, very few of the promoting trusts escaped re-organization. That drastic medicine agreed with them, however, and in course of time their securities came all right again. On the whole, it would be hard to say if the public has been better or worse for the trust companies of 1888-89.

Opinions will differ widely as to how Kaffir finance should be classified—whether as legitimate or illegitimate. The kindest thing to say of it, perhaps, is that it has seen a good deal of both. In its hot youth, twenty years ago or more, it was a diggers' gamble and produced a good many unsanctified money bags. But when Cecil Rhodes and his associates appeared on the scene it improved its manners and by slow degrees got the entrée into Park lane. In the end it

bought up Park lane and made it an annex of the Rand.

The first Kaffir boom, that of 1887-88, was only a preliminary canter. The real boom did not arrive until 1895, and there can be no question as to how it should be classified. Of all the gambling manias the City has ever known this was the rankest, the wildest, and the most disastrous. More money was made and lost in it than in any half-dozen previous booms and panics. It ruined ten times as many people as the South Sea bubble, and no doubt it had an indirect share in precipitating the Boer war. Whether it be a mere coincidence or something more, it is a strange fact that hardly one of its leaders survived it more than a few years. The Barnatos are nearly all gone, and every big Kaffir firm has lost one or more of its partners. Even the two chiefs of the Anglo-German South African Imperialists—Cecil Rhodes and Alfred Beit—both died comparatively young.

The next episode of illegitimate finance which distinguished the quarter-century was the Whitaker Wright campaign. Unlike the Hooley escapade, which was a mere burst of all-round lunacy, this was the work of a clever but unscrupulous artist. If he had remained in his proper country, the United States, Whitaker Wright might have been alive still and hobnobbing with Harrimans and Hawleys in Wall Street. His wholesale combination of promoting, stock rigging, cornering, and plunging generally was much too big for the City. The only place where it could possibly have succeeded was New York. There Whitaker Wrights abound in every skyscraper, and nothing he ever did in Lothbury would have been considered more than smart in Broadway.

Meanwhile it is a comfort for the City to think that the race of financial freebooters is fast dying out. There has been no daring operator since Whitaker Wright, and it is hardly likely there will be another for a long while. That particular financial game is played out. Through painful experience the public has learned its tricks and now fight shy of them. In this respect—and it is a very important one—the City has advanced greatly in the past quarter of a century. The company-promoting form of illegitimate finance, for which a slovenly law feebly administered was chiefly to blame, can no longer do much harm. It has been found out, and, until it invents new traps for the investor, will have a poor living.

Legitimate finance, to which we now turn, is a much more savory subject than the illegitimate sort. In this the past quarter of a century has been prolific. There has been an immense expansion of banking, both home and foreign, in the City. Home banks have undergone a large amount of consolidation, and their management is now concentrated in a few strong hands. They do not, however, enjoy any monopoly, nor are they ever likely to. There are too many active foreign banks planted all round them to give them a chance even to think of getting the whip hand entirely. But the Bank of England holds it for them, which comes to the same thing and is less invidious.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

JAFET LINDBERG is at Seattle.

FRANK KEITH is at Pioneer, Nevada.

H. C. HOOVER has returned to London.

O. B. PERRY has returned to New York.

H. W. TURNER is at Good Springs, Nevada.

J. R. FINLAY is expected in San Francisco.

GEORGE T. COFFEY is on his way back to Dawson.

ALLEN H. ROGERS has returned to New York from Chile.

H. FOSTER BAIN is expected in San Francisco on April 1.

R. A. LINTON, of Inquerres, Colombia, is in San Francisco.

L. C. CHURCH, of Joplin, has been examining mines in Oklahoma.

R. C. SHAW is examining mines in Tuolumne county, California.

E. G. R. MANWARING has left Cananea to accept a position at Butte, Montana.

EDWIN E. CHASE has returned from Juneau, Alaska, and is now in Oaxaca, Mexico.

EDWARD STABLES, of London, is examining mines in the Kennedy district of Nevada.

C. A. PRINGLE is now manager for the Yampa Mining & Smelting Co. at Bingham, Utah.

JOHN B. FARISH was delayed in San Francisco by illness; on recovering, he went to Denver.

W. L. COBB has returned to San Francisco from Granite Basin, Plumas county, California.

W. B. DEVEREUX & SONS have moved their office from 15 William street to 64 Wall street, New York.

W. E. THORNE has been engaged for inspection work in Brazil, and sailed from New York on March 25.

D. J. COOK succeeds H. M. ADKINSON as manager for the New England Gold & Copper Mining Co., at Bingham, Utah.

WALTER W. BRADLEY has resigned as assistant manager to the Ventanas Mining & Exploration Co., in Durango, Mexico, and is now at Berkeley, California.

GEORGE O. BRADLEY, manager of the Silver Peak mine and mill, has returned from Salt Lake City. He will shortly take charge of the Ray mine, at Kelvin, Arizona.

GEORGE W. TANTAU, superintendent of the copper mines being worked by the Pacific Improvement Co., at Ione, Amador county, California, was in San Francisco this week, purchasing machinery for the company.

GEORGE E. COLLINS is about to retire from the active management of the Argo Mining, Drainage, Transportation & Tunnel Co., at Idaho Springs, and will be succeeded by Roscoe B. Morton. Mr. Collins will remain associated with the company as consulting engineer.

Obituary.

WILLIAM WALLACE CHISHOLM died on March 18, at the age of 67. He was one of the notable men of Salt Lake City, where he had lived since 1869. In the unfolding of the mineral resources of Utah he has achieved rare distinction. He was the leading spirit in the development of the Emma mine, one of the famous silver-lead bonanzas of the Alta district, a property which he managed with great success. Even more conspicuous was his connection with the Centennial Eureka, at Tintic, Utah, a property which has become one of the dominant factors in the development of that State. Under his direction the Centennial Eureka paid in dividends \$2,110,000, and was then sold to the United States Mining & Smelting Co., of Boston, for \$2,100,000. Mr. Chisholm has been identified with the industrial life of Utah in every direction. He was noted for his philanthropy and for many public spirited acts which have promoted the welfare of his adopted city.

General Mining News.

ALASKA.

The report that the Chicago creek coal mines had been purchased by the Westinghouse Electric Co., proves to be untrue, though negotiations had been made between these parties about the construction of a power plant for general mining uses in the Peninsula. It now appears that the Alaska Fuel, Power & Transportation Co. of New York is undertaking to furnish means for the economic working of the Seward Peninsula, in much the same comprehensive way that the Yukon Gold Co. is operating the Klondike region.

ARIZONA.

MOHAVE COUNTY.

A rumor is current in Kingman that a strike of gold ore has been made in one of the dikes near Mud Springs by E. W. Walker. The strike was made on a vein running in the direction of the Pilgrim mines and is about half way between Burns' ranch and Mud Springs.

PINAL COUNTY.

Contracts for the new 2000-ton Miami mill which is to be erected at the properties of the Miami Copper Co. at Miami, near Globe, have been closed in New York, and work will begin before long on the construction of the plant.

Papers have been filed in Florence recording the deal made three months ago, whereby Lewisohn Brothers, of New York, acquire the property of the Kelvin-Calumet Mines Co. for \$2,000,000. The terms are that \$300,000 is to be spent in developments in the next year, the balance of the price then to be paid if the property develops as specified.

YAVAPAI COUNTY.

(Special Correspondence).—The Big Stick Co., operating on the Santa Maria, in the Eureka district, has a most promising gold mine. A 20-stamp mill is practically completed and a 500-ton cyanide plant will be ready for use in the near future. Four thousand feet of work has been done on the property, principally in shafts No. 3 and 9. Considerable ore is blocked out on the 100 and 200-ft. levels, but too much water has been breaking in to make deeper workings desirable until the mill is ready to use the water that will be pumped from the workings. Fifty-five men are employed in two shifts. Thomas E. Campbell is superintendent of this property, as also of the Haynes Copper Company.

Prescott, March 19.

YUMA COUNTY.

The people of Bouse and Salome are making a fuss about new discoveries of bonanza ore in the Granite Wash range to the north of the Santa Fé railroad. They claim that prospectors are flocking in from every State, and are sending out samples worth hundreds of thousands per ton. J. J. Sullivan and Homer King, a real estate man, are the principal boomers of the discovery.—The old Desert mine, situated 2½ miles north of Vicksburg, is being prepared for extensive operations. Josiah Winchester states that he has all the material on the ground for his new 10-stamp mill and that he will build it at once. The Desert group comprises 12 claims and is divided about equally on either side of a porphyry dike. A new well at the Desert furnishes all the water for any mill which may ever be installed. It is 90 ft. deep and has 60 ft. of water. There are already some 20 houses in the camp.

CALIFORNIA.

HUMBOLDT COUNTY.

Work is in active progress at the mines at Orleans, owned by the California Dredging & Mining Syndicate, of which Fred T. Hale is superintendent. The mine is now being opened up on a large scale and is backed by New York capital. Four giants are being used under a head of 450 ft.

The mine was formerly known as the Orleans Bar Gold Mining Company.

MADERA COUNTY.

Plans are being prepared by the Mud Springs Gold Mining Co. to erect a mill with a daily capacity of 50 tons of ore. There are 15,000 tons of ore blocked out in the mine, and over 1000 tons of \$6 ore on the dump. C. M. Johnson is president, S. M. Stenhouse vice-president, and F. O. Horn, secretary.

NEVADA COUNTY.

The El Oro Quartz Mining Co. has been formed with a capital of \$100,000 to operate the Marcotte mine at Gaston. The directors chosen to serve the first year are S. W. Wilcox, of Oakland, Baker W. Badger, V. W. Lothrop, and E. A. Gray, of Berkeley, T. B. Gray, of San Francisco, and Harry G. Gray, of Nevada City.

SHASTA COUNTY.

James McBride and Al Graham, two pocket-hunters, found a small ochre seam on the east side of the river from Coram, from which they extracted \$1600 in a day. The pocket was near the Pioneer ditch that furnished water to the Old Diggings district in early days.

SIERRA COUNTY.

A rich strike is reported from the Fairview mine at Relief Hill, which is being developed by Charles Wilson, of Downieville. Free gold occurs in a streak of black manganese on the hanging wall. A 10-stamp mill will be built in the spring.—The new tramway being built for the Gray Eagle mine at Gold Point is fast nearing completion. The cable is being put in place and will soon be in running order. The electric plant is also nearly installed.

SISKIYOU COUNTY.

The old San Jose ditch, originally opened up by John Chase for placer mining, is being repaired by a force of 30 or 40 men. This ditch originally cost \$125,000. It starts about 11 miles above Scott Bar.—The Quartz Hill hydraulic mine is running night and day with three men on each shift. The giants have been working for two or three months under a pressure of 350 ft. Captain Noonan, of San Francisco, is the owner and operator. T. F. Magoffey is working five men at the Dunn and Vanderlipp mine on Scott Bar. No bedrock has yet been found, although the work has gone down about 30 ft. He has a pressure of about 250-ft. head at the giants.

TRINITY COUNTY.

The Gem placer mine near China Flat, on the border between Humboldt and Trinity counties, is in successful operation, but their equipment is not yet complete, as owing to the heavy fall of snow this season, they were unable to transport all of their machinery. Part of this is at Korbel, awaiting the opening of the roads, after the snow has melted in the mountains.—For some years there has been an agitation to build a State highway through Siskiyou, Trinity, and Humboldt counties. Small appropriations have been granted, but attempts are being made to change the route to one along the Mad river; whereas the road of most benefit to the mining population would be one following the valley of Trinity river from North Fork to Willow creek in Humboldt county, as a wagon-road already exists, connecting Willow creek with Korbel and the railroad.—A 10-in. shoot of rich ore has been struck in the Enterprise mine, on the east branch of the North Fork of Trinity river. The find was made in a drift from the 500-ft. winze, which was sunk in the Lone Jack tunnel, 1000 ft. long. Boston people own the property. George Stenwick is superintendent.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Mammoth mine on Brown Mtn. has been taken over by a syndicate headed by B. J. Martelon, of Silver Plume. The bond of \$25,000 is to be taken up by May 15, while a large working fund has already been subscribed. Martelon states that a concentrating plant of 25 tons capacity daily will be erected.

while machine drills are to be installed. Work has been under way for the last eight months, and an orebody is exposed 6 ft. wide, worth from \$22 to \$25 per ton in silver, lead, and zinc.—A new strike was made this week on the Gambetta property, situated on Republican Mtn. The discovery was made where the Gambetta joins with the Peters vein. There is showing an 8-in. streak of ore that carries 55% zinc, 30% lead, with 1 oz. gold, and 80 oz. silver per ton. W. A. Wood, the manager, states that the compressor and machine-drills will arrive in a few days, when work will be resumed in the adit on the Washington vein.—R. B. Morton, of Idaho Springs, has been appointed manager of the Newhouse adit, succeeding G. Collins, who remains as consulting engineer. During the last week 60 new 3-ton cars arrived and are now being used to relieve the congested condition of the tunnel workings. During the month of February the advance made was 225 feet.

GILPIN COUNTY.

The Fifty Gold Mines Corporation has shipped 1173 oz. bullion as a result of a 30 days run. Most of the ore mined has been from the Bobtail and Fisk veins at a depth of 1400 ft. The developments during the past few months, under the management of Marshall D. Draper, have opened up large orebodies in the lower workings. The main shaft is to be deepened 200 ft., and the Gregory cross-cut on the 1400-ft. level is to be continued. Employment is being given to 125 men.—Work is to be begun at the Carroll mine in the Eureka district. A 6 by 8 in. engine and a 35-hp. boiler have been delivered at the mine, and I. F. Dawson will soon have the shaft unwatered.

TELLER COUNTY.

A district to the southwest of Cripple Creek is being developed that has previously received but little attention. J. M. Small and others are working a group of claims on Mt. Flagstaff, sinking a 2-compartment shaft on the Homestake lode. The ore found is oxidized quartz, and assays about \$9 per ton. Not far beyond this property is the adit of the Red Cloud Mining & Milling Co. This has been driven a total distance of 706 ft. and has opened up a mineralized dike fully 18 ft. wide.—The British-American Mining Co. has shipped 17 cars of ore from the Dante No. 2 shaft on Bull hill since March 1. This leasing company is mining ore from the fifth, third, and first levels, and the shipments settled for to date have brought returns of \$18 to \$34 per ton. The total production from the Dante mines for the six months ending December 31, 1908, was \$59,356 and the total output to date \$535,800.—The Golden Cycle Co. will adopt a concentrating system for its new plant near the shaft of the mine, instead of a cyanide installation, such as has been recently adopted by the Portland company. The resulting concentrate will be sent down to Colorado City for final treatment.

The quarterly report of the Gold Dollar Consolidated Co. shows that the lessees have done about 825 ft. of development work at an average cost of \$15 per foot, and that the company has done about 100 ft. more in dead work. A dividend payment of 1 $\frac{1}{2}$ c. per share is to be paid on April 10.—Measurements taken at the Drainage tunnel, on the evening of March 16, show a gain of 476 ft. for the three headings. The distance from the portal to the breast was on that date 5383 ft., and the two headings of the Intermediate shaft 801 and 751 ft. respectively, making a total distance of 6935 feet.

IDAHO.

IDAHO COUNTY.

C. E. Semple, owner of the Buck Horn mine, in the Four Mile country, 14 miles from Elk City, has just struck a well-defined vein, 15 ft. wide, of good ore at a depth of 60 ft. The vein has been traced for more than 1000 ft. and shows the same kind of ore all along.—More than 50 properties in the Elk City district are ready for placer mining, and prospectors are locating claims which have made good showings. The Chicago Dredging Co., of which P. J. Jennings is manager, will begin work early in April. A ditch eight miles long will be constructed to furnish

water for the properties owned by the Chicago company. There is an abundant supply of water this season.

KANSAS.

CHEROKEE COUNTY.

The greatest achievement recently made in the Galena camp is the draining of Short Creek bottom, which was a tract extensively mined in the early days, but abandoned when the water became unmanageable. The work was done by the Lockport Mining Co. Many old miners hastened to secure leases, and when the ground was unwatered 16 companies were ready to start work.—A. O. Ihlsing is rapidly sinking a 6 by 16 ft. shaft north of Galena. The shaft is going through solid rock at the rate of 8 ft. in three shifts. The capping of the shaft has been set in concrete.—The latest interest in the Baxter Springs camp centres in the tract between Baxter Springs and Keelville, where leases on thousands of acres have been taken to be prospected for oil, gas, coal, galena, and zinc-blende.

MICHIGAN.

Underground conditions at Trimountain remain unchanged. Shaft No. 4 continues in copper ground of exceptional richness, and with shaft No. 1 furnishes the bulk

The Missouri-Kansas Zinc Belt.

of the 'rock' being shipped to the mills. The north drifts on the fourteenth level in shaft No. 3, and the north drifts on the fourteenth and fifteenth levels in shaft No. 2 are in about 250, 600, and 300 ft. respectively, and are all breasted in good copper ground.—The A shaft at Isle Royale is being sunk steadily, and has reached a depth of 200 ft. The ground carries considerable epidote, but is so far barren of copper.

MISSOURI.

JASPER COUNTY.

(Special Correspondence.)—The old Plymouth Rock mill, northeast of Joplin, which has been idle for a long time, and was in a bad state of repair, has just been remodeled and made ready for operation. Pumping has been started, and the ground will be worked to the 100-ft. level, where there is still a good showing of ore.—Harry Gundling has recently moved the old Maude L. mill from its former site to the new position in Chitwood, at the Cumberland, which now has two shafts down to the 160-ft. level. Underground work has been under way for a long time, so that the new mill can be kept supplied with ore.—The old Emperor mining tract, southwest of Joplin, is being revived. The shallow deposits have been worked, and the shaft is to be sunk to extract a deposit between 145 and 156 ft. The property is near the new Matthes Bros. mill. A 45-ton

steam-shovel has just been installed in an open cave in the Mohler-Smith ground, at Carl Junction. The cave is 1100 ft. long by 200 wide. A 250-ton mill is on the lease and plans are under way to erect a second one of 150 tons capacity.—A new company, the Nashville Investment Co., has begun operations in the Zincite camp, on the Fisher and Renfrow lands. Both tracts were mined extensively for shallow ore some years ago. On the Fisher tract five shafts are in ore, all above the 100-ft. level. Two shafts on the Renfrow land have revealed a rich run of zinc-blende. A contract will be let at once for a 150-ton mill.—A large zinc-blende deposit was found east of Carthage, in the bed of Spring river, where blasting was being done to enlarge the mill-dam at Forest Mills. The find is important, being the first made in that community, and the neighboring land-owners are much interested and may start prospecting.

Joplin, March 20.

MONTANA.

FLATHEAD COUNTY.

George McKay, Charles McDonald, Duncan McDonald, and Samuel Rabekin are the owners of the Missouri group of

Map of Butte District.

claims on Leigh creek not far from Libby. There are seven claims in the group and gold ore and galena have been found on each claim. About 200 ft. of development work have been done.

SILVER BOW COUNTY.

(Special Correspondence.)—The Ophir mine, which becomes the property of the newly organized Butte Central Copper Co., was formerly an asset of the Butte Central & Boston, a bankrupt concern, the new company being really a re-organization, with a capitalization of 250,000 shares of the par value of \$10 per share. Half of the stock has been issued to pay off the obligations of the old company, and the remainder stays in the treasury. The directors of the new company are: Sir Frederick W. Borden of Ottawa; Willard E. Robinson, George F. Woodley, W. Harry Thompson, and Freeman I. Davidson, of Boston; William H. North, Robie W. Tufts, William G. Burns, and W. R. Tillinghast, of Providence, R. I. The Ophir is a developed mine, having a shaft 550 ft. deep. The property has been a considerable silver producer, and on the lower levels the ore has been increasing in copper, offering hopes that with greater depth the ore will be found to carry good commercial copper.—The management of the Davis Daly Copper Co. hopes to make a producing mine out of the Colorado before many

more months have passed. Recent diamond-drilling has disclosed a good orebody at a depth of 1400 ft., about 385 ft. west of the shaft. The cores assayed 3½ to 5% copper. A cross-cut is being run toward the orebody and another will be made from the 1200-ft. station. The Davis Daly Co. is doing no work at any of its other properties.—Reports from No. 1 mine of the East Butte Co. indicate that a good copper mine is being opened there. The drift on one of half a dozen veins that have been cut by the 900-ft. cross-cut has progressed a distance of about 75 ft., and the size of the orebody continues uniform, from 7 to 8 ft. wide, and the copper content also holds well, running about 8% copper and 10 to 12 oz. silver per ton. The drift has about 160 ft. more to go until the west end-line of the company's ground is reached. There are eleven shafts on the company's property, No. 1 and No. 11 being the main ones. It is the intention of the company to extract ore and store it while the development work and cross-cutting goes on.—Work is progressing rapidly in the Copper Eagle mine, a silver producer in the northern part of the Butte district. The new level at a depth of 350 ft. is being opened. East of the shaft the drift on the vein has been extended 265 ft., and on the west 45 ft. A recent shipment of ore returned \$100 to the ton. The company will install a complete electric plant, as it is needed for the economical handling of the ore already blocked out, and is expected to pay for itself in a few months in the saving of coal. President Burnett claims that ore to the value of the entire capitalization of the company, \$250,000, is blocked out in the mine.—The Parrot Co. is developing the Parrot vein on two new levels. No large or very rich orebodies have yet been opened, but the showing on the 19th and 20th levels is better than on the 18th. The Parrot vein is very erratic, the ore being found in pockets and bunches. At some points the vein is 60 to 100 ft. wide, and at others it is a mere streak, so thin that miners follow it with difficulty. It is quite certain that it will be a long time before the Parrot Co. can again pay dividends from ore mined from the Parrot mine. However, the Little Mina, which is practically a new mine, is developing into a good producer, a lot of development work being done on the 10th and 12th levels.

NEVADA.

CHURCHILL COUNTY.

(Special Correspondence.)—The Nevada Hills mine, at Fairview, is being further developed by a force of 20 men. The principal vein, which is a fissure in the andesite, is opened by a 400-ft. shaft and four cross-cut adits, which, with the drifts and winzes, aggregate about 6000 ft. of work. The ore consists of quartz carrying free gold, sulphide and chloride of silver occurring in shoots, and chimneys at the intersection of the main vein with cross-fissures. The dividends paid by the Nevada Hills in the last three years amount to \$375,000. Some experimenting has been done in the way of tests by concentration and cyanide, with the view of milling the lower-grade ore. Among the men interested in this mine are W. V. Rice, J. R. Davis, J. A. Kirby, J. T. Hodson, W. H. Clark, and W. H. Webber, the last named being the manager.

ESMERALDA COUNTY.

J. H. Mackenzie has confirmed some of the reports about a big strike in the ground of the Consolidated company. It appears that the find is within the boundaries of the Combination No. 1 claim, instead of on the adjoining Mohawk, as was first reported. The Secretary, A. H. Howe, says the ore-shoot has been opened on the fourth, fifth, and sixth levels, and they are now 40 ft. above the fourth level and still raising in ore. No stoping has yet been done on the orebody, but in development alone ore worth about \$300,000 has been extracted in the last two weeks. The centre streak assays high up in the thousands of dollars, and in places the orebody is shown to be 30 ft. in width.

James D. Sword announces his intention of building a 400-ton smelter at Luning to treat the copper ores from the Mayflower and Consolidated Mines Co. With him are associated L. L. Patrick and C. Walter Geddes, former superintendent of the Consolidated.—Numbers of outsiders are

coming to Mina to take advantage of the new discoveries close to town. On the Elizabeth claim, assays made from samples taken from different portions of the ground gave returns of \$74 gold per ton.—W. E. Lindsay has sold his quarry near Mina to Davis Bros., of Yerington. This quarry is said to be the only black Egyptian marble workings in the United States. The marble is jet black, laced with gold, and variegated with green and copper colored veins. The purchasers acquired 65 acres from Lindsay and have about 60 acres of their own adjoining it. The quarry will be equipped with polishing machinery and cranes to handle large blocks. One block taken out recently weighed 45 tons.—Suit for \$500,000 damages has been filed in the District Court by D. Mackenzie & Co. against the Mohawk Mining Co., George Wingfield, and James R. Davis. One hundred thousand dollars of these damages are against Wingfield and Davis as being bondsmen for the Mohawk company.

LANDER COUNTY.

Hill Top seems to be making progress in the finding of new orebodies. The Philadelphia Western Co. has lately cut a 5-ft. vein on the 200-ft. level which shows an average value of \$70 per ton, with a portion that is of shipping grade. There is a shaft 90 ft. deep, and an adit is being run to cut the vein on which it has been sunk.

LYON COUNTY.

L. Humphries, consulting engineer for the Mason Valley Mining Co., states that that company has now secured all the required water-rights, and a smelter-site consisting of 1500 acres in Yerington valley, and that with the opening of spring, work will be at once started upon the erection of a smelter by the Mason Valley Co. The Southern Pacific railroad has promised the immediate building of a railroad through the Yerington district.

NYE COUNTY.

(Special Correspondence).—A winze west of the main shaft at the Sphinx has cut two bodies of ore between the 110 and 200-ft. levels. They are said to be from four to six feet wide and worth from \$12 to \$15 per ton. R. B. Wampler, president of the Round Mountain-Fairview Co., announces that the mine and mill will commence activities at an early date. A fair reserve of ore has been developed.—Contracts have been signed for the delivery of electric power to the Round Mountain mill, and the current will be available by May 15. The mill is producing more than \$30,000 per month.—It is reported that the mill of the Montgomery-Shoshone Co. is to be enlarged at an early date.—The Springdale mill, at Beatty, is being placed in shape to treat ore from near-by properties.—A new compressor and machine-drills are being installed at the Round Mtn. Daisy mine.—It is rumored that a 12-ft. orebody running \$100 per ton has been cut on the 210-ft. level of the Pioneer mine. About 90 tons of ore are being produced per week. Arrangements are under way to install a 40-hp. hoist, a 60-hp. engine, and a 6-drill compressor. This machinery is expected within a few days.

Round Mountain, March 17.

(Special Correspondence).—The flow of water into the Mispah shaft of the Tonopah Mining Co. has increased during the past week from 25,000 gal. to 37,500 gal. The Aldrich pump is kept running three hours per day, in which time it empties the 12,500 gal. sump at the 1200-ft. station three times. The shaft is now down 1284 ft. The Red Plume shaft of the same company is down 500 ft., and a quartz vein has been disclosed at the bottom. So far it proves to be of no value. Four hundred and forty-two feet of new ground were broken during the week in the Tonopah Co.'s ground. The mill crushed 2650 tons of ore yielding 62 bars of bullion valued at \$825 a bar, and 28 tons of concentrate worth \$525 per ton. The total shipments from the above amounted to \$65,900.—The Montana Tonopah opened up 204 ft. of new ground during the week, and crushed 1030 tons of ore, of which 646 were from the Montana and 384 from the MacNamara. The bins for MacNamara ore have been cleared out, and from now on the whole 40 stamps will be run on Montana ore only. A small

filter of the Butters type is being installed to further clarify the solution from the Butters filter. A large gold solution tank is being fitted up as a settling tank to increase the slime-settling capacity of the plant.—The double-compartment shaft in the MacNamara is now down 640 ft. in the dacite intrusion. It will be put down to 800 ft., and prospecting will be begun at that level. The company sent 200 tons to the Western Ore Sampling Works at Millers, in addition to the 384 tons sent to the Montana mill.—The Belmont, West End, Jim Butler, and Tonopah Extension did the usual amount of development work last week, the Belmont leading with 214 ft.—The King Solomon Mines Co., controlled by the Forman brothers of Tonopah, have decided to let leases on their property, and during the past week several lessees started work on the company's ground. The property is 9 miles northwest of Crow Springs and 35 miles northwest from Tonopah. It is a silver-lead ore, galena being the predominant mineral.—The Broken Hills mine at Clifford shipped 25 tons of ore valued at \$200 per ton to the smelter from Tonopah. The ore was hauled to Tonopah from Clifford by 10-horse teams, and thence shipped by rail. Tonopah, March 22.

So great is the placer activity at Manhattan that all of the Mustang, Mustang Extension, and Rainbow gulch areas have been leased, and one shaft has been started on the lower part of Main street. The whole gulch down to Central and out into Smoky valley is a hive of industry.

At a stockholders' meeting of the Tramp Consolidated, held in Philadelphia, a minority report was presented to the directors, requesting that they submit a final report to stockholders, discharge all workmen, and close down everything indefinitely.

NEW MEXICO.

GRANT COUNTY.

The development of the Ridgewood claim of the Eureka Sylvanite Mining Co. is at present attracting the chief interest in the camp. The Ridgewood vein has been opened up in ten different places over a length of about 600 ft., mostly by shallow shafts and open cuts. An adit is being driven to cut six stringers of high-grade ore which have been found on the surface. One of these is about 8 in. wide and assays \$96 per ton, while others show coarse gold without need of assaying.

OKLAHOMA.

OTTAWA COUNTY.

Northwest of the main Miami camp three mines have recently opened up deposits which far surpass the general run of ore. They are the Golden Hen, the Consolidated, and Jennie May. The ore was found at a depth of about 100 ft. Plants have been erected on the Golden Hen and Consolidated, of 200 tons capacity in each case.

OREGON.

HARNEY COUNTY.

A valuable opal find has been made on Thousand creek, in the extreme northwestern part of this county and about 20 miles west of Denio. The scene of the find is close to a 'petrified forest' which probably has a similar origin to the opals. The stones discovered by L. Denio and his partners are said to be of good size and quality.

JOSEPHINE COUNTY.

The shipment of 17 tons of ore from the Oriole mine at Galice brought J. C. Mattison returns at the rate of \$210 per ton. This ore has come from a vein 40 ft. wide which contains a narrow streak of high-grade in the middle. Mattison will at once put up a stamp-mill and a cyanide plant of sufficient capacity to take care of the low-grade ore as fast as it is mined. As a preliminary, the construction of a wagon road from Galice to the mine, a distance of two miles, is to be begun immediately.

TEXAS.

The new law passed by the Texas legislature provides that all land now owned by the State shall be thrown open to mineral prospectors, locators, and purchasers. The law

specifies that a claim shall consist of 21 acres or less, and describes the methods by which the prospector must establish his rights. The owner of a claim shall have one year from the date of filing his affidavit in which to prospect his claim. The price to be paid for claims shall not exceed \$25 per acre. It is believed that the new regulations will greatly advance the mining industry of the State, as most prospecting has heretofore been done on private lands.

UTAH.

BEAVER COUNTY.

The Frisco Consolidated Mining Co., whose property has the extension of the Horn Silver contact vein, is expected to resume operations next month. Development consists of a 550-ft. shaft, with some cross-cutting and drifting. The equipment comprises holsting and pumping machinery, and further development will be carried on. D. P. Rohlfing of Salt Lake City is manager.

JUAB COUNTY.

E. C. Coffin, superintendent for the Lower Mammoth Mining Co. at Tintic, is putting down a new 3-compartment shaft in place of the old one. The work has already passed the 900-ft. level, and is progressing about 10 ft. per day. At the present rate it is said that the 1200-ft. level will be reached by the middle of April, and development work will then begin in earnest on the 1000, 1100, and 1200-ft. levels. —The shaft of the Emerald Mining Co. at Tintic is now down 1092 ft., and as soon as the 1100-ft. mark is reached, drifts will be run to find the continuation of a narrow but very rich streak previously discovered in a winze. J. L. Yundt is general manager.—Development work upon the 300 and 400-ft. levels of the Yankee Consolidated mine has now nearly reached a point where the Beck Tunnel vein should be driven into. Prospecting is also under way upon the 500 and 600-ft. levels, but L. Merriman, the superintendent, has temporarily suspended work below the 600-ft. level.

SALT LAKE COUNTY.

(Special Correspondence).—There has been a consolidation of the holdings of the Butler-Liberal, Butler M. & M. C., Ben Butler No. 3, Utah Development Co., Hooghly, and Vespasian, aggregating 275 acres on Markham canyon, in Bingham district, by the North Utah Mining Co., of which W. D. Bohm, of Salt Lake, is manager. The old workings amount to over 20,000 ft., and a new shaft is to be sunk, with connections to various parts of the group. The ore is mainly lead-bearing, but it is accompanied by silver and a little copper. It occurs in shoots within fissures in quartzite. Some shipments have been made lately the gross value of which was about \$60 per ton. The shipping, however, is incidental to development, and Bohm's plans contemplate deep work. A big tonnage of milling ore has been opened, but is not blocked out. The capital employed in this enterprise is all British. This consolidation does not include the Utah-Apex group, as was previously published.

The Utah Copper Co. has 80 acres of overburden on its Bingham canyon property, with an average depth of 70 ft., all of which contains copper ranging from $\frac{3}{4}$ to 1%. D. C. Jackling will put up an experimental plant for the treatment of this low-grade material before summer.

The Utah-Apex property, although adjoining the Utah Consolidated in the Bingham canyon, is not a copper property. Of course it has copper ores, but the bulk of them carry a prepondering value of silver and lead. The last 97 smelter shipments by the Utah-Apex Co. have aggregated 7158 tons, of a gross value of \$152,600, or \$21.25 per ton in silver and lead. The Utah-Apex Co. is now shipping 150 tons of ore per day and from these shipments is earning at the rate of about \$1000 net per day.

SUMMIT COUNTY.

Work at the Daly West mill, which has been closed for several days on account of the lack of water, has been renewed. The water for the mill and the mine will be received from Ontario lake, which has begun to flow again.

TOOELE COUNTY.

Work on the International Smelting Co.'s railroad, from

the Salt Lake Route tracks through Tooele City on to the smelter in Pine canyon has nearly reached Middle canyon, where a trestle will be built. At the rate progress is being made it is a certainty that the railroad will reach the smelter site by May 1.

PHILIPPINE ISLANDS.

A. Heise has gone back to Manila after testing the ores of, and purchasing the plant for, the San Mauricio Mining Co. This property consists of 10 claims near the town of Mambulao, Camarines, on the east coast of Luzon. There are three known veins on the claims, and it is on the San Mauricio vein that the greater amount of work has been done. The new equipment consists of a 20-stamp mill and concentrating plant, obtained from the Traylor Engineering Co. The situation of the mine and mill, near the ocean, gives the advantage of cheap transportation, and the concentrate obtained will be shipped to Australia or America. Accompanying Heise was D. E. Blake, a mining engineer from Colorado, who is to be in charge of the work at mine and mill.

CANADA.

BRITISH COLUMBIA.

The Ymir Mining Co. has issued \$2,000,000 in common stock, and has already raised over \$100,000 with which to prosecute development in its mines at Ymir. Diamond-drilling is now in progress at the property for prospecting 500 ft. below the 1000-ft. level.

The Granby Consolidated Mining & Smelting Co., of Grand Forks, has bonded for \$100,000 a group of promising copper claims, near Tassu harbor, on Moresby island, the second largest of the Queen Charlotte islands, and has made one payment upon the bond. These claims, which are owned by Messrs. Connors, Parks, and others, are situated in the immediate neighborhood of the group in which Thomas Taylor, the minister of public works, holds a quarter interest.—A fire took place in a west stope on the 400-ft. level of the Centre Star mine last week. R. H. Stewart, the manager, and his assistants were soon on the spot, and were able to prevent the fire spreading to the shaft and upper levels. At the time the fire was discovered only a few men were in the mine, and no lives were lost. The cause of the fire at present is unknown.

MEXICO.

FEDERAL DISTRICT.

The repairs to the timbering of the Mexico shaft are finished. During the time this work has been progressing the mill has been kept running on ore accumulated on the dumps.—The report of development in the Descubridora mine at El Oro shows that the east and west cross-cuts are 270 and 228 metres long, respectively. A dike has been passed through, at one side of which was found some rich ore in the Chihuahua mine, to the north.

OAXACA.

F. W. Taylor has opened work on two of his properties in the Santiago Minas district. The properties are known as the Copper Queen and Copper King.—Preparations are being made for the re-opening of the work on the Zavaleta mine. The property has been idle for the past year.

The Ocotes mine, situated between Oaxaca and Ejutla, on the Teruel road, is soon to install diamond-drills for prospecting below the sixth level. The mine is the property of the Teziutlan Copper Mining & Smelting Co., and it is practically assured that this company is arranging to build a smelter on this mine. The diamond-drills will be installed at once and the vein will be thoroughly prospected at least 1000 ft. deeper.

SONORA.

The Greene-Cananea Co. is preparing to add 80 vanners to its present concentrating equipment, which consists of two mills with a daily capacity of 2400 tons of ore. L. D. Ricketts, the designer, says that the additional vanners are to be put in for the purpose of increasing the efficiency of the plant and not with any idea of increasing its capacity.

Special Correspondence.

DENVER, COLORADO.

Forest Service Defended.—Gilpin County Revival.—Cripple Creek Development.—Tariff on Lead.—New Oil Field.—Geological Report.—Record Tunnel Driving.

During the week ending March 20, Gifford Pinchot, chief of the Forest Service of the United States, met in debate the various individuals and associations that have grievances to remedy and suggestions to make regarding amendments in the regulations of the Service. On March 15 he met a delegation of the American Mining Congress, composed of Callbreath, Mills, Bancroft, and Daniels. The questions that were brought before the last convention of this body concerning the hardships to prospectors and miners under the regulations were discussed. The contention is that prospectors have been driven from the preserves by the rangers, and that permission has been refused to miners to cut timber on their claims. The conference between the members of the Congress and Mr. Pinchot resulted in the endorsing of several amendments to the regulation to correct the hindrances to prospecting. On March 16, at the Forest Service branch office, which has been doing business in Denver since the first of December, Mr. Pinchot received delegations, and conferred with the local officers and rangers. On that evening, he addressed the joint assembly of the Colorado legislature, at whose request he came to Denver. Here he met in debate, Mr. Ammons, State Senator, a practical stockman of Wyoming and Colorado. Among other things, Mr. Pinchot said that President Taft had given him authority to say that he is heartily in favor of the present policy of the Service. Mr. Pinchot declared that the general policy of creating and maintaining the National Forests had been accepted by the people of the United States and may be regarded as definitely and finally fixed, and he urged the co-operation of the American people. He warned the people of Colorado against the Power Trust, which is gradually growing to be the biggest trust of all. He read from the pages of the Bureau of Corporations, showing that the Central Colorado Power Co. was deeply encroaching on the water resources of the State and already included as subsidiaries the Leadville and Colorado Springs Lighting companies, Northern Colorado Power Co., Denver Gas & Electric Co., Summit Power Co., and others; that the stock of the company is held by the Westinghouse and General Electric companies, and that the American Gas Co. has a ruling hand in its affairs. The head of the forestry department showed that this company already controlled a great part of the waters of the State, and were it not for the Forest Service, the great power companies would soon control them all. Mr. Ammons made a strong point as to the right of the United States Government to set aside vast tracts of land in any State and assume jurisdiction over the lands to the exclusion of the State. He said the small stockmen were at the rangers' mercy, and that there were men living on the reservations who were in a state of terror through fear of the power of the ranger. Mr. Pinchot showed that were it not for the Service there would be no small stockmen, but that all the grazing land would be in the control of the owner of large herds. On Wednesday, Pinchot addressed a meeting at Boulder, and met delegations from Fort Collins and Longmont. On Thursday he again conferred with the American Mining Congress, and also met the Chamber of Commerce of the city of Denver. On his trip Mr. Pinchot is accompanied by A. F. Potter, assistant forester.

The beginning of the revival of Gilpin county is seen in the opening of several old mines which have been idle for years. The Topeka group, in Russell district, a former good producer, idle for eight years, is to be re-opened. The Alps property on Quartz hill is being worked by lessees and a recent shipment returned 7 oz. gold per ton. The property is owned by Hal Sayr, of Denver. It is reported that another good vein has been cut in the heading of the New-

house tunnel, which is now under the 'Patch' on Quartz hill. The lode is supposed to be either the Illinois or the Pocahontas. The Jim Blaine group and Daisy mill-site in Independent district has been sold to the First National Bank of Central City. The deposit is the largest low-grade orebody in Colorado. The value will run from \$3 to \$4 per ton. The ore reserve is estimated at 1,000,000 tons. It is the intention to erect a large mill of 300 tons daily capacity.

A syndicate of Boston capitalists has taken a five-year lease on the property of the Free Coinage Co., of Cripple Creek, to operate that property below the 550-ft. level. The property consists of the Pinto, Rising Sun, Wilson, Bison No. 2, and Pueblo claims, forming a compact group on Bull Hill. These have been recently examined by Forbes Rickard, of Denver, who will act as the consulting engineer for the new company, called the Altman Leasing Co. Sixteen sets of lessees are now working on the mine above the 550-ft. level, and these operations will not interfere in any way with the operations of the new company on the lower levels. Operations under control of the Altman L. Co. are to commence immediately on the Pinto claim, and the shaft, which is now 575 ft. deep, is to be sunk to 1000 ft. No lateral work will be done until a depth of 800 ft. is reached. A new hoisting plant will be erected in place of the old equipment now on the property. The production of the Free Coinage to date is over \$2,000,000 from above the 550-ft. level, and a heavy production is expected from the lower workings.

The State Geologist, R. D. George of the University of Colorado, has completed his first biennial report covering the work done by the Survey since its establishment two years ago. The principal features of the report are the surveys of the Hahn's peak region, the Montezuma district in Summit county, the tungsten area of Boulder county, and the topography of the foot-hills from the Wyoming line to a point south of Boulder.

The proposed reduction of the tariff on lead from 1½c. per pound to 1c. per pound is causing uneasiness among the lead producers of this State. A committee has been appointed by the president of the American Mining Congress to make vigorous protest through the Colorado representatives in Congress. There are many mines in Leadville, Clear Creek, San Juan, Summit, Park, and Chaffee districts working on so small a margin of profit that they will have to close if the proposed reduction is made.

Excitement has been caused at Grand Junction by the reported discovery of oil in Fremont valley, just over the Utah line. More than 25,000 acres have been located, and prospectors are flocking to the district in large numbers. At Florence, all operators whose wells show signs of exhaustion are preparing to deepen them. This is due to the success of lessees of an old well belonging to the Rocky Mountain Oil Co. By deepening this to 3000 ft. a flow of 100 bbl. per day was secured.

The Gold Dollar Con. M. Co. has declared a dividend of one-half cent per share, to be paid on April 10. The production from this mine has been larger during the past three months than during any like period in its history. Those interested in the Necessity claim on Battle mountain have ended the litigation, which has tied up this property for the last six years, by forming a new company. The directors of this new Uintah-Ajax Gold Mining Co. are residents of Denver and Colorado Springs. The Necessity claim contains three acres, is patented, and contains valuable ore. Work will be started at once. Record-breaking progress is being made at the Cripple Creek Deep Drainage Tunnel. Between March 1 and 17, 476 ft. was gained. The distance from the portal to the first heading is now 5383 ft., and from the foot of the intermediate shaft a total of 1552 ft. has been driven. The annual meeting of the stockholders of the Jennie Sample Con. M. Co. promises to be a sensational affair. It will occur at Cheyenne, Wyoming, on April 2. The fight is to oust S. S. Bernard, now president of the company. Charges of mismanagement have been made by the opposition, and letters asking for proxies have been issued by both parties.

LONDON.**El Oro Mines.—Kolar Goldfield.—A Chameleon Company.**

The chairman of the Exploration Co., R. T. Bayliss, has just returned from an extended visit to Mexico, where he has been making special examinations of the El Oro and the Mexico Mines of El Oro, which are properties under the guidance of his company. He has issued an interesting statement relating to the Mexico Mines of El Oro which shows that the mine is becoming a larger proposition than was originally expected. When it was first opened, the deposit consisted of three or four approximately parallel veins not exceeding 7 ft. wide, so that the recent developments which prove that the low-grade or barren ground between these veins has become mineralized at several points, have brought a pleasant surprise. These united veins are for a width of 65 ft. averaging \$15 per ton. At numerous other points the veins are found to be 15 and 20 ft. thick. On the No. 6 level is found a vein of rich ore which may turn out to be a continuation of the bonanza of the adjoining Esperanza mine. The rich ore which is found will be sorted up to \$150 or \$200 per ton and shipped to smelters, the waste being sent to mill. It is not at present intended to increase the output of the mill, but to wait further developments. The mill is up-to-date, consisting of 40 stamps, tube-mills, and cyanide plant. It treats about 9000 tons per month, and yields a monthly profit of £12,000. Its capacity has proved to be nearly 50% higher than was originally estimated.

Though the general prospects and conditions in the Kolar goldfield, of India, are not in the aggregate quite so satisfactory as might be hoped, yet the original Mysore mine is going as strong as ever, and is indeed in a remarkable current of prosperity. Its old rival, the Champion Reef, is in poor ground, and is making only a fraction of its former profits. It is the more interesting therefore that at all three principal centres of development the Mysore continues to open up wonderfully well. At Ribblesdale shaft-work is going on at the 3908-ft. level, and the vein is found to run from 23 to 34 dwt. in value, and from 2½ to 3 ft. in width. At McTaggart's the lowest workings, 2385 ft. deep, show a vein 24 dwt. in value and 6 ft. wide. Developments during the year have added to the ore reserves, which now stand at nearly a million tons, equivalent to five years' supply, averaging over 1 oz. per ton. A year ago I mentioned the adoption by John Taylor & Sons, the managers of this group of mines, of the principle of paying for all costs out of revenue instead of issuing new shares when special extensions were contemplated. The effect on the nominal dividend is apparent in the results for 1908 which are now published. Though the prosperity of the company has been fully maintained, the rate of dividend is only 115% as compared with an average ranging from 130 to 150% during the previous seven years. To the casual observer (and I am afraid the bulk of investors come under this category) the company does not look as successful now as formerly. The difference is accounted for by the inclusion of nearly £80,000 in the expenditure account for new plant, which formerly would have been met by the issue of new shares. The production during the year was valued at £848,145 from 206,170 tons of ore, and £350,055 was distributed as dividends. It is worth noting that since the commencement of operations in 1884 the company has produced gold aggregating a value of £10,785,687 and has distributed approximately half of this in dividends.

In one of your recent editorial notes you referred to the disinclination of an English mining company ever to give in, and instanced the Briseis. An even more characteristic case is to be found in the history of a company called Tarkwa Consols. It was formed in 1901 to acquire properties on the West Coast of Africa during the time when that part of the world was 'the fashion.' No sort of practical mining was ever done nor was the value of the property ever properly ascertained. When West Africa went out of vogue two or three years ago, and the chairman of the company, Mr. Francis Allen, was becoming interested in Cornish

matters, the company abandoned its name and assumed the title of Cornish Adventurers. Options were taken on various properties in Cornwall in conjunction with Mr. Allen's other companies, notably on Wheal Sisters at St. Ives. The failure of this mine to materialize, together with a slump in tin, made the company's operations in Cornwall of no avail. Fortunately for the company, West Africa has been looking up again during the last six months, and money has once more gone in that direction. Certain people in London approached the company with a view to resuscitating its claims in Tarkwa, and a favorable arrangement has been made whereby a diamond-drill prospecting expedition is to be sent out to thoroughly test the veins. To keep up with the times, the company's name has been moved back once more to Tarkwa Consols, and Mr. Allen and his shareholders are as sanguine of success as they ever were.

MEXICO.**Guanajuato Activity.—Zacatecas.—Black Mountain, Sonora.—****Oaxacan Railroads and Mines.**

Notwithstanding the low price of silver none of the Guanajuato properties have closed. On the contrary, many have increased their output, so that the total production of shipping ores and of bullion continues well above the quarter million pesos per week, and it is expected that this year will see a material addition in new mines and mills. The Santa Natalia, being worked by Mexico City capital, has its small new mill nearly ready for operation, and the Tres Coronas and Margarita of the Mexican Mining Co., in which development has yielded such splendid results, will begin shipping as soon as the mill of the Vignos company is completed. This is north of La Luz. The stamps are lifted by eccentrics instead of by cams, and a higher capacity is claimed. It will treat ores from the Tres Coronas, Margarita, and Los Reyes. The Guanajuato Amalgamated Gold Mines Co. is installing the Butters filter system in its Jesus Maria mill, and is running a surface tram to the old Villa Rino dumps. The Guanajuato Mines Syndicate has resumed work on the Loreto, and is sinking the shaft; while the Pinguico company is sinking a new shaft to develop the side veins. The San Angel, of the Puertocito de La Luz, and El Roble, are both in good ore, and the unwatering continues at the San Cayetano. In El Cubo the tunnel has been completed to the Villalpanda shaft, a distance of 7000 ft., and will, of course, be of great assistance in mining and handling the water. The Guanajuato Reduction & Mines Co. has also put in a surface tram, for handling the ores on the dumps at the San Antonio, from Tepeyac to Valenciana, whence the ores will be taken by aerial tram to the Bustos mill. Cortlandt E. Palmer and associates, among whom are E. A. Wiltsee and Frank G. Peck, have obtained control of La Luz and Refugio and other properties in La Luz district, comprising approximately 1500 acres, and have organized what will be known as the Refugio Mines Syndicate for developing the properties.

Zacatecas is greatly encouraged over the work being pushed forward in that camp. The 300-ton cyanide mill, and the steam-electric power-plant for the Bote mine are practically completed, and will soon be handling ore from the large body of low-grade material blocked out in this mine. The Magistral's new 300-ton smelter is also nearing completion, but in the meantime the mines of the company are producing as usual; and the Nueva Quebradilla is constructing a 75-ton concentrating plant for its low-grade sulphides. The Zaragosa, Cartagena y Anexas, and the San Roberto are nearing the productive stage, and it is said a strong American company is after the Veta Negra, on which, if obtained, work will be pushed.

In the State of Sonora, outside of Cananea, comparatively little new work is going on. The Black Mountain M. Co., at Cerro Prieto, has obtained a Federal concession, similar to that of the Cananea Consolidated Copper Co., for the introduction of fuel-oil free of duty, and will soon use oil at its steam-plants. The Venturilla M. Co., operating near Santiago de los Caballeros, of which A. R. Crowell of Los

Angeles is president, is developing a fine body of lead-silver ore under the management of H. F. Wilson. The West Coast Co. is opening good ore in the Todos Santos, near Santa Cruz in the Cosalá district; and the Mina Grande, in the Badiraguato district, controlled by Jack Crawford of San Diego, is now on the shipping list, sending its product out by way of Culiacán.

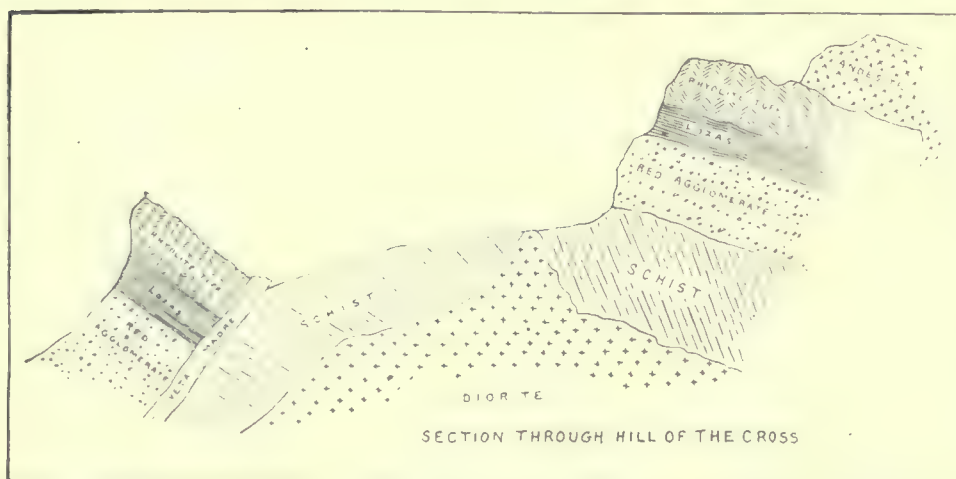

In Oaxaca the old Hamilton railroad, better known as the San Juan Taviche, which was taken over by the Mexican Southern, is now to be pushed to completion by that company from Ximatlán to San Gerónimo, and will open up almost the whole of the Taviche district and give an outlet for its ore. This should enable the Oaxaca Smelting & Refining Co. to obtain supplies of smelting ores, and it is understood that H. M. Holbrook, president of the re-organized company, is making preparations to blow in the furnaces immediately upon completion of the railroad. At the San Carlos, in Taviche, which has been worked in rather a haphazard manner, a more vigorous campaign is to be inaugurated, and shaft sinking and drifting will be pushed. For the San Francisco mine a new mill will be erected in Taviche, and the Santa Isabel is to be opened up by Los

In Tepic the Certuchena mine has been taken over by the Tepic Gold Mining Co., of Los Angeles, California, a concern controlled by Marshall P. Wright. The property is situated only 5 miles from the line of the new S. P. branch, that is, the Cananea, Rio Yaqui & Pacific railway. A 10-stamp mill is to be erected immediately. The ore is said to yield a recovery of over \$8 per ton, or 80%. The company claims to have ore enough developed to feed a 10-stamp mill for 15 years. The Clark Copper Co., with extensive holdings in Sonora, is now in control of George H. Stewart, J. R. Smurr, and J. Ross Clark, representing the discontented minority stockholders, 'Patsy' Clark of Spokane and his associates having retired from the directorate. The headquarters of the company will be in Los Angeles, California. The operations will be confined to the Magistral mine, in the State of Sonora.

TORONTO, CANADA.

Gowganda District — Transportation Problems. — Cobalt Stocks. — Dividends Payable. — Crows Nest Coal.

The Gowganda district is attracting more attention than Cobalt, where the possibilities for the prospector, the promoter, and the miscellaneous crowd that always flocks into a new mining district, is superior. The situation is growing serious, owing to the difficulties of transportation, the improvised sleigh-road from the end of steel at Sellwood being utterly inadequate for the volume of traffic; moreover, this is likely to break up at any time on the advent of spring weather. It is estimated that some 12,000 people are in the country and only a few days' provisions on hand. In the

The Veta Madre, Guanajuato.

Angeles capital. In the Sierra Juarez district the old Mexico M. & M. Co. is completing the erection of a 30-ton cyanide mill, with stamps and Frue vanners, to be operated by two turbines; it will also have a three-mile aerial tram to the mine. This means a new lease of life for that company. The San José de Gracia, in the same district, is adding a cyanide plant to its mill; and on the Rosario, Corazón, and Manchezo, development is being pushed by Maurice Clark and associates of Mexico City. Near Oaxaca the Santa Catarina has made its first clean-up; the Natividad is nearing completion with its 200-ton cyanide plant; the Frida M. & M. Co. has ordered a 30-ton mill; and the final payment has been made on the Zacaleta by the Pittsburg-Oaxaca Co.; development will proceed more rapidly in future. The Victoria of Taviche has been taken under a lease by English people, and the Victoria of the Tepada Mining Co., in the Totalapám district is to have a cyanide mill. The Guebeshe mill in the Ocotlán district has been put in commission. On the Mascota mine, San Carlos, the Pioche adit has cut the vein at 125 metres, and the Mascota adit is in 60 metres with a like distance still to run before reaching the vein.

The Calabacillas mine in the extreme western part of Chihuahua near the border of Sinaloa, has shown remarkable results. It was purchased a little more than a year ago by William H. Brevoort, and has been managed by Arthur J. Underwood. The mine produced nearly \$100,000 from 7000 tons of ore in 1908, thus showing an average value of \$14 per ton. The ore is gold and yields 80% by amalgamation, and a further recovery of 80% of the gold remaining in the tailing is made by cyanidation. An adit is being driven which at a distance of 3000 ft. will cut the vein at a depth of 1000 ft. below the outcrop.

intervening season, between the breaking up of winter and the opening of navigation, the community will be practically isolated, and unable to obtain fresh supplies, so that unless a sufficient supply be laid in meanwhile, much hardship may be experienced. The Canadian Pacific railway has arranged for a canoe freight route on the opening of navigation from a point on the line 35 miles west of Sudbury, following a number of lakes and watercourses to Gowganda. Steam launches will be put on the long stretches where they can be used, with horses on the principal portages to facilitate trans-shipment. An impetus has been given to the boom by a Government sale of lots in the Gowganda town-site, 130 lots being disposed of by tender at an average price of \$136 per lot, realizing a total of \$17,664. The highest price paid was \$412, and the lowest \$25. This week a large deputation from the north country waited upon the Provincial Government and strongly urged the immediate extension of the Canadian Northern railway to the Gowganda district, and the building of a permanent wagon-road.

Cobalt stocks continue depressed, in sympathy with unsettled conditions in the American market. The multitude of new Gowganda flotations also absorbs a good deal of the money that would otherwise be invested in 'Cobalts.' Cobalt Lake experienced a rally a few days ago on account of the discovery of a new 12-in. vein in the cross-cut from No. 6 shaft at the 135-ft. level. The vein is rich in native silver, which also appears in the wall rock for 12 in. on each side. The cross-cut is being driven close to the McKinley-Darragh line, where some good veins are looked for. An important find has been made on the Nipissing vein No. 64 at a depth of 172 ft. It is here 5½ ft. wide, 18 in. of which assays over 2000 oz. per ton. The Crown Reserve has declared a quarterly dividend of 6%, with an additional bonus of 2%

payable April 15. The Chambers-Ferland recently made a good discovery in cross-cutting from No. 2 shaft at the 80-ft. level, the vein being 4 to 6 in. wide, containing cobalt with silver. High-grade ore averaging over 5500 oz. is being taken from the adit at the 150-ft. level. In the Columbus, at a depth of 250 ft., and 51 ft. east of the shaft, a 2-ft. body of galena has been found. The Temiskaming, concerning which disquieting rumors have been afloat, has declared its regular quarterly dividend of 6% to be paid April 1. During the fiscal year it produced 1,026,285 oz. silver, or \$494,211, and has 16,000 tons of ore on the dump valued at about \$250,000, which will be concentrated. The Buffalo has declared its regular quarterly dividend of 5% payable April 1, and an extra 3% dividend to be paid May 15. Little has been heard lately of the Foster since its good ore gave out, but work is being kept up in the extraction of low-grade ore and in prospecting for new veins under Glenn lake. Some 600 tons of ore on the dump will be treated at the Cobalt Central concentrator. Shipments from Cobalt for the week ending March 13 amounted to 527 tons, from the following mines: Crown Reserve, 50; City of Cobalt, 30; Coniagas, 30; Kerr Lake, 30; La Rose, 103; McKinley-Darragh, 28; Nipissing, 130; O'Brien, 32; Temiskaming, 30; Temiskaming & Hudson Bay, 30; Trethewey, 32 tons.

An important change has taken place in the directorate of the Crows Nest Pass Coal Co., Fernie, B. C. At the annual meeting held here on March 12, G. G. S. Lindsey, president, Robert Jaffray, vice-president, Sir Henry M. Pellatt, and E. R. Wood, all of Toronto, declined re-election to the board. The new board of directors consists of Elias Rogers, Toronto; Mr. Clough, New York; J. P. Graves, Spokane; W. F. Robertson, Granby, Que.; E. C. Whitney and H. McGiverin, Ottawa; and R. M. Young, Toronto, secretary. The new board represents the interests of James J. Hill of the Great Northern railway, who, it is understood, has for some time had a controlling interest in the Crows Nest Pass Co. The reason assigned for the action of the retiring directors is that they did not wish to be longer responsible for the management of the company when the real controlling power was in other hands.

SALT LAKE, UTAH.

Daly-West Resumes.—Dividends.—Ohio Copper. — Cole-Ryan Option. — Ray Con. Copper. — Mason Valley. — Lead Producers Meet.—Yampa Smelter.—Utah United.

The Daly-West Mining Co. has again been able to resume operations at the Park City properties, after a cessation of one week. Both the mine and mill were out of commission as a result of the scarcity of water. The winter freeze and the snows in the high mountains had completely shut off the flow from Ontario lake, but arrangements have been made with the Wabash Co. to provide water for the mine, and the lake will provide the mill. The first quarterly dividend of 30c. per share, aggregating \$54,000, has been posted. The last dividend was paid by this company in December 1907. The company has a surplus of about \$320,000, after having paid dividends aggregating \$5,877,000. The Silver King Coalition Mines Co., also of Park City, has posted its quarterly dividend of 15c. per share, amounting to \$187,500. This silver-lead producer has paid over \$11,500,000 to the shareholders. Among recent dividends posted by the Utah mines are: Utah Consolidated, \$150,000; Colorado, \$80,000; Sioux Consolidated, \$35,000.

Colin McIntosh, general manager of the Ohio Copper, states that they have continued the Mascotte tunnel 250 ft. beyond the raise that connected with the upper workings. They still have 250 ft. to go to reach the west end of the group owned by the company. The raise in the vein is being continued, and will be sent over to the hanging wall side where the sulphide deposit found on the upper levels showing 20 to 25% copper is expected to be cut.

John D. Ryan has wired that he will be unable to be here for a week to examine the Colorado mine in Tintic and the Tintic smelting plant. The option which the Knights gave the Cole-Ryan syndicate on those properties expired on

March 20, but it has been extended indefinitely. That the option-price has been reduced is acknowledged by the Knights, who want to get out of the smelting business and confine their operations to mining. They are anxious to have the smelting operations at Tintic continued.

D. C. Jackling, general manager of the Ray Consolidated, says that they have added in excess of 2,000,000 tons of copper ore to the reserves during the past month. He will visit the mines in Arizona immediately, where he spends half of the month, dividing his time between this and the Utah Copper properties in Bingham. Next month he expects that there will be double this amount added to the reserves, as the drills prove the ore. For a time the drills were set across the country at a considerable distance apart to prove the limitations of the ore zone. Later the ground has been blocked and holes are sent down in each 10-acre block.

The most important strike yet made in the Mason valley properties occurred within the past three days. On the fourth level they have broken into the sulphide deposits. The drift, after passing through the replacement deposits, is now in 20 ft. on this high-grade ore. Through 12 ft. the ore contains 12% copper and the next 8 ft. shows an average of 27.77. The entire face gives an average of 10% copper. Practically all this ore is of smelting grade.

A number of prominent mining men from Colorado, Utah, Idaho, and other Western States are holding a session in this city to consider the proposed reduction in the lead tariff. A memorial is to be sent to Congress protesting against the reduction. The Coeur d'Alene mine-owners are represented by Harry L. Day of the Hercules mine, W. Clayton Miller of the Federal, J. F. McCarthy of the Hecla, M. A. Folsom of the Bunker Hill & Sullivan, and G. Fred Fratzer. J. F. Callbreath, secretary of the American Mining Congress, with headquarters in Denver, is in attendance.

The Yampa mine and smelter in Bingham canyon, controlled by Grant B. Schley and associates of New York, are now under the management of C. A. Pringle, formerly manager for the Calera Mining Co., at San Isidro, Chihuahua. The Yampa produces sulphide of copper averaging close to 2%. The daily output of 750 tons is smelted at the Yampa plant, which contains screening bins, 9 McDougal roasters, 3 reverberatory and 3 blast-furnaces. The coarse and fine are separated by $\frac{3}{8}$ to $\frac{3}{4}$ -in. screens. The fine receives a desulphurizing roast in the McDougal furnaces, whereby the sulphur is reduced to $4\frac{1}{2}$ to 5%. It then passes to the reverberatory furnaces which produce a 30% matte. About 500 tons of fine ore per day are thus treated. The coarse ore, amounting to 250 tons per day, is smelted in one of the blast-furnaces, the other two at present being idle. In the same furnace the matte from the reverberatories is re-smelted. The result of smelting the crude ore with the 30% matte is a product that runs only 25% copper. The low concentration of the coarse ore brings the average percentage down. This matte is treated in converters, there being two stands, which are operated on two shifts per day. In the shells a silicious lining, carrying some gold and silver, is used, and by reason of the matte being so low-grade a larger amount of lining than usual is used. The converter-slag is poured into the blast-furnace settler and the slag from the two is disposed of together. F. J. Murphy, smelter superintendent, states that the company will probably erect a sampling plant and prepare to treat custom ore as well as that from its own mine. The blowers, supplying blast for the furnaces and converters, are operated partly by steam and partly by electric power.

The Utah United Mines Co., owning the old Okay and Skylark groups, situated near Solas station, Beaver county, has kept a small force developing during the past winter and has now a 300-ft. incline, from which cross-cuts have been driven to the 4-ft. vein of ore at three stations. The vein is on the contact between limestone and granite. The ore assays well in copper, with some gold and silver. It also runs high in iron, and only about 18% silica. A. J. McMullen, the manager, contemplates making ore shipments later in the year.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Spheroidal Weathering of Dikes.

The Editor:

Sir—Herewith you will find the photograph of a dike seen near Butte, Montana, that to me exhibits at least one peculiar feature. This dike is found in a cut on the Northern Pacific railroad about eight miles southeast of Butte and about one mile northwest of the continental divide. It is exposed in this cut to a depth of 20 to 30 ft. The railroad is running nearly east and west, while the direction of the dike is approximately N. 45° W. and S. 45° E. The

Curious Weathering of Diabase Dike Near Butte, Montana.

dike has an average thickness of nearly 9 ft. and dips northeast at an angle of 87°; in other words, it is practically vertical.

The country rock is the Butte granite. The dike is composed of diabase, as determined by the microscope, having the typical structure and composition. When fresh the rock is black, but weathering has caused most of it to assume an ashen color.

The dike has a peculiar appearance: it is composed chiefly of globular masses of rock varying in size from a few inches up to about two feet in diameter. These masses are interlocked on their outer edges and each mass is separated into concentric layers in much the same manner as an onion. These layers are not uniform in thickness; they are remarkably regular and distinct, and have comparatively smooth surfaces. This concentric division is wanting or scarcely observed in the fresh rock, but is very marked where much weathered. It seems to be an

excellent illustration of circular parting due to weathering. Some of the globular masses do not possess this circular separation to a degree that is distinct, but it is noticeable in all. On both sides of the dike along its contact with the granite, alteration is apparent, especially in the dike itself; the portion affected extends to a depth of several inches, while in the granite the alteration, if any, has a depth of only a fraction of an inch. The dike rock in this altered area is usually not in globular masses, but is arranged in vertical layers varying in thickness from less than one to several inches. In these vertical layers the rock is more compact, of finer texture, but much more weathered than in the main body of the dike. Vertical layers also occur occasionally between the globular masses, but these may be part of the masses assuming a vertical position.

J. R. VILLARS.

Butte, January 20.

The Editor:

Sir—Mr. Villars is to be cordially commended for preserving the picture and preparing the description of the dike near Butte. These fleeting phenomena, which are visible today and gone tomorrow, need to

Spheroidal Weathering in a Dike in a Granite Quarry at Barre, Vermont.

be recorded in some publication of reference, or else they are lost to science. The dike is a fine illustration of spheroidal weathering and of sheeting, both forms of breaking-up being in large degree referable to strains produced in cooling. Weathering has brought out the shelly or onion structure, but one cannot well resist the conviction that some internal structure has facilitated the assumption of these peculiar shapes. A molten dike that has come to rest between cold walls would be expected normally to break up into prisms, whose axes would lie perpendicular to the cooling surface, but if, as was probably in large part the case in this instance, the walls had become heated so that there were no great contrasts in the transmission of the heat in various directions, the prisms might pass into spheroids. The sheeting appears to be approximately tangent to the large spheroids, and to mark a central area. If the sheet-

ing is not due in any respect to faulting movements, its layers may perhaps be considered as the coats of spheres of large radius.

In former years in the hills a few miles north of Butte there were piles of apparent boulders of the Butte granite due to the shelling-off of angular jointed blocks, a result that we often see in the granitic areas of the West, but the process would seem to be radically different from the dike in question. The spheroids, moreover, seem not to be spherulites, due to radiating crystallization, since Mr. Villars' thin sections afforded no such suggestion. In a small way the spherulites are sometimes developed in diabasic rocks, as reference to the peculiar variety called 'variolite' will at once remind a reader. While great spherulites, even larger than the spheroids of the dike here described, were once found by Whitman Cross in the pitchstone of Silver Cliff, Colorado, the Montana dike can be best explained by contraction strains.

It may be of interest to place with Mr. Villars' picture another of a basaltic dike in the granite quarries of Barre, Vermont. The photograph was taken about six years ago by George J. Finlay.

J. F. KEMP.

New York, March 2.

Panama Canal.

The Editor:

Sir—I trust you will pardon this personal letter from a stranger. I have been a subscriber to your paper for some time, and have read practically all of your editorial utterances with interest and approval, except in the case as below noted. Your ideas on mining geology and mine finance and promotion and local political influences of a malign nature, strike me as level-headed, courageous, and independent. But your editorial of December 19 on the Panama Canal has surprised me. For example, you do not understand the complacency with which official circles in Washington regard the payment of \$40,000,000 for what could have been bought for five million. I happened to be on the Isthmus officially accompanying the Commission at the time transfer was made, and was familiar with the situation. The old Commission, you will remember, recommended the Nicaragua canal as being better than Panama on account of the expense that would accrue in getting possession of Panama. The Panama Co. wanted, I think, one hundred and ten millions for their rights, property, work done, etc. The Commission estimated that if Panama could be bought for forty million dollars, it would be the more advantageous route. From personal knowledge of the Commission, I believe this was a conscientious estimate, and, in addition, showed shrewd management on their part, as the Frenchmen promptly tendered their canal at that figure, knowing that their property would be much reduced in value if the United States built a canal at Nicaragua.

I have made no estimate of the value of the enormous stock of metallic material on the Isthmus, of the Panama railroad and its terminals, its steamboats, etc., of the vast number of buildings, and the

great amount of useful work accomplished, but I am positive that your estimate of five millions is ridiculously low. The Panama railroad is worth more than that. I have understood that even its La Boca terminal cost one million dollars, and I have no doubt that a careful appraisal of the benefit that the present canal received from the French work was well worth the forty millions paid for it. It is, of course, possible that the United States might have driven a harder bargain, owing to its ability to ruin the French company by building a canal at Nicaragua, but I should regard that as an immoral performance alongside of which the strategy in assisting the Republic of Panama into being, to keep Colombia from holding us up for forty or fifty million dollars for the privilege of doing her a great financial favor, is small in comparison. There are two sides to that Panama Republic question, and while the highest grade of national ethics may have been scarred a little in the process, the great good to humanity that will come from the canal, seems to me to amply justify the strategical moves that were adopted to outwit the scheme, which I think even the Colombians themselves would admit as unfair.

In a recent issue you discuss the point of the Gatun Dam having been moved eleven times. I think this is utterly absurd, as I have watched that dam quite closely, and I don't think it has moved an inch since the minority report decided upon it. You hint rather darkly of the corruption which led to the withdrawal of John Finley Wallace. I am curious to know what grounds you have for this. I kept close track of everything that occurred at that time, and while Mr. Wallace's action was inexplicable, and I think Mr. Taft's indignation perfectly justified, I have come to the conclusion that the reason Mr. Wallace left Panama was precisely the same as the reason why the Governor of California did not leave Pasadena during the railroad strikes at Sacramento, a reason proper and all-powerful from their point of view, but which neither of them would feel like publishing.

My greatest astonishment at your editorial, however, is at your remarks concerning Lewis M. Haupt, with whose personal equation I am quite familiar, including his capabilities as an engineer. You can get some light on the latter proposition if you read the discussion of paper No. 14 in the *Transactions* of the American Society of Civil Engineers covering the International Engineering Congress in St. Louis in 1904. The paper was by the undersigned, and the discussion was by Mr. Haupt and the undersigned. The matter is quite lengthy, and on a generally unfamiliar topic, but if you are interested in either Mr. Haupt or his theories of ocean bar improvement, a careful reading of the matter would repay you for the time involved. At one time, Mr. Haupt organized a company to promote his peculiar jetty-theory on the same lines as his proposition for the Columbia river bar. The plan was to have a central trust in New Jersey, with local companies wherever harbor improvements were to be made by the general Government. These companies could have a secret membership covering local politicians capable of influ-

encing the National Government to adopt the Haupt plan as the one preferred by the maritime and other important interests of the port. I really doubt if Mr. Haupt appreciated the enormity of his proposition. On another occasion, at a meeting of the Isthmian Canal Commission, the question of unit-prices was being discussed, and the majority of the Commission was about to decide on some figures that Mr. Haupt thought were very high. He expressed his criticism thus: "Why, gentlemen, if you adopt such high unit-prices, you will kill the whole canal proposition." I am reliably informed by a member present that there were nine pairs of astonished eyes turned on Mr. Haupt at this, and he abandoned his suggestion.

CASSIUS E. GILLETTE.

Philadelphia, March 11.

Deep Lead Mining in Australia.

The Editor:

Sir—In replying to Newton B. Knox's kindly comment, in your issue of December 5, on my article published by you on October 24, I desire to say that the facts given by Bewick, Moreing & Co. and by Mr. Algernon Moreing with reference to the Loddon Valley mine were quite correct, namely, that the wash is spotty and that the gold contents are unevenly distributed. But they did not, as far as I know, venture on an explanation of the possible reason why this is so, although, in my opinion the cause is evident, as was the failure of the Spring Hill & Central Leads mine about 20 miles nearer the source of the same lead. Another cause may perhaps have contributed to the failure of the Loddon Valley, this being the junction with the main lead, not far above the Loddon Valley shaft, of one of the largest tributary leads in the district, which may have helped to scour the main lead and cause the spotty nature of the gold content. The exact point of junction has not been determined, but all are agreed that it cannot be far away from the Loddon Valley workings.

The Loddon operations demonstrated another potent fact, which, with or without the combination of the tributary lead, would account for the spotty character of the wash, namely, in the extreme north workings gravel was found within 5 ft. of the back of the main level, and this was 50 ft. too deep for the lead. Possibly, had the level been driven farther north the gravel would have been found still deeper. This abnormal hole must have been caused by volcanic action after the gold was laid down in the old river bed, but while the river was still in existence, and the hole caused the river to scour its bed by emptying its contents for a time into the disturbed area, just as Mr. John W. Gregory, of the Victorian Geological Survey, described what took place ages ago in the property of the Spring Hill & Central Leads. The two mines are similar in that they each have an extinct crater of a volcano within a short distance of the lead, and as the Professor said, "when the volcano was active it was creating a vacancy under the bed of the old river until the crust became so thin that it broke and the river poured its

contents into the hole." This in itself would be sufficient to cause the scour and account for the patchy character of the wash. Therefore, I consider that the failure of the Loddon Valley Co. is not evidence that our clay leads do not contain gold in large quantities, but simply proves that the Company was unfortunate in having cut the lead at a point where an extraordinary set of circumstances combined to deprive them of a satisfactory return for their outlay.

D. H. BROWNE.

Rutherglen, Victoria, February 9.

Electrolytic Amalgamation.

The Editor:

Sir—In your issue of February 13 there appears an article by E. E. Carey describing an apparatus for electrolytic amalgamation, which, though of the crudest form of construction and inadequate to give the results described, is the basis of a more effective apparatus covered by the patents of W. J. Jory and J. H. Jory, extending from 1893 to 1904.

The perfected electrolytic sluice comprises a scientific system in which the electric forces employed are adjusted by means of instruments of precision, and in which the chemical solutions used are closely conditioned to the requirements of the ores and sands operated on. The apparatus of this system is so constructed as to be automatic in operation, needing but little attention and giving perfect recovery. This statement cannot be truthfully made in regard to such primitive contrivances as are presented by Mr. Carey to the needy millman; for crude methods ignorantly applied can never prove satisfactory.

That the results obtained by Mr. Carey, as recorded by him, are correctly stated I have no doubt; but I am certain they were not obtained by any such contrivance as he describes, nor by any means employed in so loose a manner.

J. H. JORY.

San Francisco, March 18.

What Is an Ore?

The Editor:

Sir—No sooner is a word brought forward for accurate definition than a host of others appear offering hardly fewer difficulties. Mr. Kemp has exhaustively investigated sources of information for a definition of 'ore', and in so doing has attracted my attention to an amorphous word, used quite generally in mining literature. This is 'mineralization'. It is a word loosely applied under different conditions to convey an idea which familiarity has robbed of precision. 'The entire country is heavily mineralized'; so is a vein, in the redundant parlance of the press. In both of these is lack of definite meaning. May I then appeal for further light from the learned lexicographers, and ask 'What is mineralization?'

NESCIO.

Milpitas, March 21.

Lithium decomposes water, forming LiOH. It is entirely unattached by hydrocarbons, and may consequently be preserved in naphtha or benzene.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Pre-heating of water for boiler-feed purposes is estimated to effect a saving of 1% in fuel for each 11° F. which the feed-water is raised in temperature.

False cleavage is a tendency in rocks to split at right angles to the true cleavage of the rock. It is called also 'grain', 'bate cleavage', 'rift', and 'slip cleavage.' It is a different phenomenon from jointure. Advantage is taken of cleavage and 'rift' in laying out quarries in crystalline rocks.

Garnet is exceedingly abundant, being perhaps the most characteristic mineral among those porphyritically developed in the crystalline schists. The crystals are generally from 1 to 4 mm. diam., and are likely to be more numerous along certain planes of cleavage than others, notably following the more highly micaceous layers, and being less prominent in association with the layers which are richer in quartz and feldspar.

The Bradley patent on the electrolytic production of aluminum was No. 468,148, and was issued on February 2, 1892. It accordingly expired in February last. This is the basal patent, but many other patents have been issued, which cover improvements in the process called forth in the light of experience. By the expiry of the original Bradley patent, however, the metallurgy of aluminum is practically thrown open to the world.

Fuller's earth, which is used for bleaching oils and fats, performs this office through absorption and retention of organic coloring-matter. It owes this property to the colloids which it contains, these being colloidal silicates, which in the case of fuller's earth are singular in not being destroyed by drying at a temperature of 130° C. Colloids in ordinary clay would be completely destroyed at that temperature, so that plasticity could not be again developed in the mass.

Tappet-valves in compressed-air drills are of special advantage in dry dusty mines. In the case of spool-valves the wear from dust and grit, which will unavoidably get in to some extent when the air-hose is disconnected, leads to leakage of air past the valve or piston, interfering with the action of the auxiliary ports. This will occasion irregularities in the reversal of the drill, shorten its stroke, and diminish the efficiency because of such leakage and irregularities.

Prospecting a vein by panning tests is liable to lead to error. In a case cited by Wilfrid Taylor good indications from sampling a Rhodesian vein by that method were reduced 50% by subsequent fire assay, owing to the large amount of silver alloyed with the gold. In many of the desert mines of the United States the amount of coarse gold in the leaner por-

tions of the lode is so large in proportion to the amount present in the better ore that panning tests will prove entirely misleading.

Ore-shoots, according to Waldemar Lindgren, may be classified into the following varieties: (a) magmatic segregation shoots, (b) metamorphic, (c) replacement, (d) ascending circulation, and (e) vadose. The most conspicuous concentration into shoots presented in the earlier stages of the great majority of mines are of the latter type. These, in effect, are secondary enrichments. Generally, however, they bear a close relation to primary shoots in the vein before the vadose waters had re-arranged the metallic contents.

Safety-fuse may be tested as to continuity of the powder-train in the core by means of an X-ray photograph, the powder-grains being opaque to the rays. Occasional samples cut from the coils in daily use should be thus tested from time to time, and especially if mis-fires are more frequent than usual. It may prove that a particular consignment of fuse was faulty. The X-ray test is better than a burning test, as it reveals faulty feed in the fuse-machine, which would not necessarily be revealed in burning. The burning powder-train in the fuse-core 'spits' ahead and may thus carry over gaps in a fire-test which it might not bridge in the severer conditions of actual service in blasting.

Clay is a complex mixture of a group of minerals, of which kaolin is the type. This group, known collectively as the 'clay minerals,' varies from a minimum of 12% Al_2O_3 in malthacite to a maximum of 45 in pholerite. The range of silica is from 12% in schröterite to 64 in pyrophyllite; while the range of hydration is from 5% in pyrophyllite to 35.4 in malthacite. Kaolin has the formula $\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2 \cdot 2\text{H}_2\text{O}$. The clay minerals are about 16 in number. In addition, clays contain minute particles of undecomposed original rock-forming minerals, mainly feldspars, augites, and hornblendes, with quartz, but it is evident that larger proportions of SiO_2 than the 46% in kaolin may be present in the form of secondary minerals of the clay-making sort.

The draft necessary to overcome the resistance to the flow of air through the coal on a grate of the ordinary type, having about 50% air-space between the bars, is 0.6 of the total draft required for the combustion of the coal. With a closed ash-pit and forced draft the fan must supply air to produce a pressure in the ash-pit 60% greater than the total draft as determined by the formula

$$i = \frac{f^2}{K^2}$$

where f represents the number of pounds of fuel burned per square foot of grate-area per hour. i equals the draft measured in inches of water at the end of the up-take where it joins the chimney, and K is a factor the value of which depends on the kind of fuel employed under given conditions, being usually in the neighborhood of 58.

HOW IT STRIKES AN AMERICAN.—I.

Written for the MINING AND SCIENTIFIC PRESS
By T. LANE CARTER.

To return to America after an absence of ten years causes one to feel like a Rip Van Winkle, for at this stage of American development, a period of ten years shows as much change as would a century in more settled countries. It has been my privilege to visit many of the large mining districts of the United States during the past few months, and it might be of interest to readers of this journal to know how it strikes an American to visit industrial centres of his country after so long an absence. As my time has been spent at the mines of Central and South

Since my departure from America much has been done for the farmer. With rural mail delivery, telephones, and better roads, his lot today is incomparably better than it was 10 or 20 years ago. These improved conditions are attracting a better class of people to the soil, and today we find gentlemen's sons in the agricultural schools, who 20 years ago would never have dreamed of becoming farmers. The good seed sown in the establishment of agricultural schools, and the application of science to the problems of the soil through the agency of the Department of Agriculture, is bearing abundant fruit.

Next to agriculture, one naturally enquires into the condition of forestry, as mining is so dependent upon this branch of industry. I have been shocked

Mining in the Rocky Mountains. Pack Train Arriving at the American-Nettie Mine, Ouray, Colorado.

Africa, it might prove instructive, while writing these impressions, to compare in a general way the mining conditions as they exist in America and South Africa.

As "no man liveth unto himself," so no industry exists by itself. In considering mining in the United States, attention is first drawn to the industry on which it depends, namely, agriculture. The two industries are so bound together that the success of one affects the other. Cripple agriculture, and mining is at once seriously affected.

Nothing has impressed me more in my trip through the United States than the advance in agriculture during the past ten years. Nature has endowed this land far more liberally from an agricultural point of view than South Africa. One realizes as he goes through hundreds of miles of farms in the United States, that the greatness of this country rests on the surest foundation, namely, that of agriculture.

at the ruthless destruction of trees during the past 10 years. In my own State in the South, vast areas that were virgin forests 20 years ago, are today hideous wastes. The greed for wealth has wiped out vast forests, with an utter disregard for the future of the country. We should long ago have followed the example of Sweden, Germany, and other enlightened countries, where the law enforces the planting of a tree for every one cut down. The tax of \$2 per 1000 ft. on lumber imported into the United States should never have been allowed, unless the planting of trees had been made obligatory. This tax has merely gone to swell the millions of about 27 men in the United States, who own the majority of the timberlands of the country. The duty has certainly done no good to the mining industry. I should like to see the tax reversed, and an export duty put on timber to save what we have lost. The people seem to be waking up to this question.

forestation, and in every mining centre which I visited, I found men talking on the subject, and praising the good work done by the Bureau of Forestry. Every mining man should interest himself in this subject and do what he can to encourage the planting of trees. A man who remains at one place does not realize the terrible encroachments that have gone on during the past 10 years in our forest reserves. He should take a trip through the United States to be convinced.

While on this subject of the waste and destruction of our timber, it might be well to state that one sees senseless waste in other things. I saw on my trip water-power running to waste which would long ago have been utilized in such countries as Italy and Switzerland. In Louisiana natural gas and oil is being wasted, which if saved and utilized would add to the wealth of the State. Many of our coal mines are wasting far more coal than they should. On the whole it struck me that the minimum amount of waste was in the metal mines.

A comparison of the labor conditions in the United States and South Africa would take too long; I can only treat the subject in a cursory manner. The lack of efficient labor has for years been the cry among mining men in South Africa. For a long time efficiency was low on the Rand, but recently there has been a marked improvement, and most of the creditable reduction in working costs in the Transvaal during 1908 were due to the higher efficiency of labor. I heard much also of the inefficiency of labor in this country, both East and West. This is probably due in large measure to the enormous expansion in mining operations during the last 10 years, so that the supply of good miners has by no means equaled the demand. I was told, for instance, in the Lake Superior country that the percentage of Cornishmen working there has diminished considerably in recent years, the demand for good miners farther west having been so great that many of the Cornishmen moved to the new districts. Another cause for inefficiency in some mining districts is due to the labor unions. The theory of paying a poor workman the same as a good man, and of making all men industrially equal, does not promote efficiency. Limiting the output of the laborer is the cause of inefficiency in some union camps.

The mines in Africa have not been troubled with the problem of extreme unionism. The districts are not run by unions. Those that exist do not interfere with the efficiency of the laborers, for the contract system is extensively employed, and this makes for efficiency. In going from district to district I formed the opinion that better and more efficient work was being done in the non-union districts of the United States than in those dominated by the union. I was disappointed with unionism as I found it in America today. Against the right kind of unionism I have nothing to say. The miners should be properly united to protect their interests. We all know that modern capitalism is not philanthropic; that it needs to be legislated and watched; that there are wealthy individuals in America today who would form a monopoly tomorrow if they could to control the air-

supply of the United States and charge us so much per breath; that they have adopted the Americanized golden rule as their standard, "Do unto the other man what he would do unto you, but do it first." But an improperly led, improperly organized union is a positive danger and hindrance to the miners, as many of them know to their sorrow. What unionism among the miners in the United States most needs is broad-minded able leaders, not demagogues who simply use the men and the union in order to 'live easy.' They should return to the higher ideals of unionism, which should exist for the advancement of the character and efficiency of the laborers. Workmen should realize that economic laws are as inevitable as gravity, and that decreased efficiency means higher working costs and therefore a contraction of production with a decreased demand for labor. Miners in America are much the same as in Africa—they like to roam. Frequently they are fooled by the high wage offered, and do not realize that what most concerns them is how much they can save from their earnings, and what chances of investment they may have. For instance, in a camp in the East, the miner might earn \$75 and live for \$25, putting aside \$50 per month; but he hears that 'out West' they are paying \$90 per month, and away he goes to find that he is fortunate if he can save \$40 per month in his new position.

One finds many instances of men among the miners who have the genius for saving and making money, veritable Pierpont Morgans in their smaller way. One man I met—a Scotchman—who came to this country with no money, is now worth thousands of dollars. He has never left the first mining centre he struck. All his savings he put into real estate. He would buy lots, and in his spare time, with hired help, he built houses and rented them. While others spent their nights in saloons denouncing capitalists, this man was quietly working, and today has the satisfaction of having built up a small fortune.

While I believe that the Rand has been the mining region where the frugal man could save most money, there is no question that the miner in America who wants to save has great opportunities to use his earnings in good investments. The level of wages in Africa today is no higher than in some of the better paid portions of the West. But the white workmen in this country have one great advantage over the white artisans in Africa; they have the satisfaction of knowing that they are living where the demand for white labor is constantly expanding; that when they educate their sons and daughters and give them trades, they will be employed in their own country. But in Africa, on account of the peculiar conditions, the demand for white labor is not increasing rapidly. Many a head of a family has looked forward with apprehension to the future for his sons. In America practically all the mining is done by white men; in Africa the majority of it is done by blacks.

Compared with the American underground-worker, the South African miner seems less capable in a general way. In the Transvaal it is difficult to get a white man to do a bit of everything. If he is employed on rock-drilling, he does not want to do

anything else. In America he does differently, and is therefore a more well-rounded workman. On account of the different mines he works in, the miner in this country gets a more varied experience than in Africa.

I found that wherever possible the 'dirty work' of the mine, such as mucking, is handed on to the newcomers, the Huns, Austrians, and Italians, by the Irish and Americans who formerly did this work. The Irish and Americans have gone in for 'bossing' and machine work.

In South Africa more is thought of the miner than of the mechanic, as far as wages are concerned; for years the efficient miner on contract has earned more than the mechanic or carpenter or blacksmith. This has been a sore point with the mechanic in Africa, who claims that he must give years of his life to learn his trade, while the limited knowledge of mining required to run a machine-drill in a Rand mine can be picked up by an intelligent person in six

on the whole America may learn a valuable lesson from South Africa in looking after employees. Experience on the Rand has proved that it is good business to make the lot of the men as congenial as possible. In some centres that I visited in America, the quarters and accommodations for the men might have been good places in which to rear hogs, but were scarcely fit for human beings. No self-respecting man will remain in such an environment longer than he can help, and as soon as he saves sufficient money he will go away.

It was a pleasure and contrast to go from these pig-sties to the Grass Valley district. Anyone who declares that mining is necessarily hideous, that esthetics and mining are as far apart as the poles, should take a trip to Grass Valley. There he will find that mines may be so adorned with trees and flowers, shrubs and vines, as to become really artistic and attractive. The disciples of the hideous and the unattractive in mining should pay a visit to the North Star and Empire mines in Grass Valley and be shamed into advocacy of better things.

Empire Mine, Grass Valley, California.

months. In America the mechanic earns more money than the underground-man.

On the whole the office staff in America is smaller than in South Africa. You cannot help realizing this when you go to the Homestake mine and see how few men are in the office there, for a huge concern dropping a thousand stamps. The visitor is impressed, in visiting among the American mines, with the absence of 'side' on the part of the managers, and the friendly feeling that generally exists between the man at the helm and those working under his direction. After all, this is the secret of good management, to cause every workman to feel a personal interest in the success of the concern. You do not find any snobbery among the mine managers in America. Other faults they may have, but they are not snobs.

On the whole, South Africa is far more liberal than America in providing for the comfort and amusement of the men. I saw no recreation clubs or halls at any mine of the United States to surpass the houses built for the employees of the Rand mines. Of course the stability of the Rand, and the fact that the life of the mines is assured for many years, has much to do with providing these better conditions. In America some of the large companies have done much for the comfort and recreation of the men, but

Kennedy Mine, Amador County, California.

After a tour of the United States, I realized the importance of climate in industrial pursuits. Laborers in the Lake Superior district, for instance, as on the Rand, have an advantage over men working in the hot climate of the Louisiana salt and oil deposits. From a climatic view-point, efficiency of men in Michigan is higher than in Louisiana. In a cold bracing climate a man must work to keep warm, while in the heat of the South, it requires will-power to keep up to the mark. In examining mines either in Africa or America, the question of climate should be considered.

One marked difference between American and South African mining is the attitude as to Sunday work. In the Transvaal there is a strict law against Sunday work, punishable with a heavy fine, the maximum being \$375. Under the law, necessary work is allowed, such as the running of stamp-mills, pumping, repairing of machinery, and the like, but no one is allowed to work in the mine from midnight on Saturday to midnight on Sunday, without special permission from the Government mining engineer, a permission rarely given. With the principle of the Sunday law all the mining men of the Transvaal agree. Their only contention is that the hours should be from Sunday morning to Monday morning, so as to allow a full shift Saturday nights on those mines which are

falling behind. I noticed that at some mining centres in America, they observe Sunday as completely as in the Transvaal, for instance, in the Lake Superior district. In many mining districts of the United States not the slightest notice is taken of Sunday, work being carried on just the same as on other days. We know, of course, that mining is not like a grocery business where the doors can be opened at 9 a. m. and closed at 4 p. m. A good deal of Sunday work will always be necessary, especially in running huge metallurgical concerns; but I believe there is a tendency to overdo the Sunday work, and the Transvaal law is undoubtedly an excellent one. I am sure that in American mining today too much Sunday work is being done. It is not flattering to us to know that in Africa they are able to keep huge batteries at work all the time, by working six days per week, while in America, where we claim to have 'hustling' down to a science, it is necessary to go seven days per week to accomplish six days' work. I believe it would benefit the mines if Sunday work were reduced to a minimum. The universal experience of the industrial world is that man must have a day of rest in seven, if he is to remain healthy and efficient. Even a machine must rest at times. In the Transvaal some managers try to arrange it so that a part of the men can get off on alternate Sundays. Men in the mills and cyanide plants work on 8-hour shifts, and have a 'long shift off' every third Sunday. Transvaal experience teaches the gain to be had in reducing Sunday work as much as possible. Wholesale Sunday work does not pay.

In the matter of labor-saving devices, South Africa compares favorably with America. While I saw one or two devices which could be used on the Rand to advantage, there are a few Rand 'wrinkles' that our mines could be taken up with profit. Considering the adverse conditions on the Rand, the ore is handled expeditiously. Some of the methods for handling ore in America would be out of the question on the Rand on account of the sinuous and narrow character of the veins. The efficiency of air-drilling in America struck me as being better than in South Africa, principally due to the fact that far higher pressures are used on this side. Recently the air-pressures on the Rand have been increased, and this should improve the efficiency of the drills. Small machines are also used to better advantage on this side. One is impressed with the tremendous development of compressed air in both countries during the past 10 years. The day of the hand-drilling miner seems to have passed, save for prospects and small mines where it does not pay to put in a compressor. Only a small percentage of the ore mined in the United States is broken by hand labor. I believe the same thing will soon be true in South Africa. So far the electric rock-drill does not seem to have 'caught on' to any great extent. From what I have seen the pneumatic drill is knocking the electric into a 'cocked hat.' Managers in America should watch the development of the electric furnace for sharpening drills underground. Some interesting work is being done along this line on the Rand, and if an extended test should show the furnace to be prac-

ticable, such mines as the Homestake and the Calumet & Hecla, where tons of drill steel are handled daily, could no doubt save money by the use of the electric furnace.

In America many of the larger mines make their own rock-drills and claim a saving in expense. This is not done on the Rand, new rock-drills being bought outright from the factories. In the first place skilled labor in Africa is too expensive to allow them to make their own rock-drills, and again, competition in rock-drills is so keen that machines are cheaper there than here. With the huge wall of protection around America, the makers force the mining companies to pay a far higher price for machines than they ask for the same contrivance away out in Africa. If they make a profit out of the South African end of the business, one may fancy what they make in this country at American prices.

(To be Continued.)

Tantalum until recently was little known. It is perhaps the most curious of the metals. A good deal still remains to be learned concerning it. Like most other steel-hardening elements, according to O. M. Becker, it readily combines with carbon; but the carbides thus formed are not soft, as is the case with the others, but very hard. A small amount of carbon is sufficient to carbonize a large amount of tantalum. It is considerably more than twice as heavy as iron, bulk for bulk; is about as hard, when in the annealed state, as soft steel; and has a tensile strength nearly a third higher. When hardened by alternate heating and hammering, metallic tantalum becomes so hard that a diamond-drill will scarcely touch it, while at the same time it retains a remarkable degree of toughness. No information is at hand as to its specific influence upon high-speed steel, but it is known that one maker uses tantalum in steel for drills, dies, and tools of like nature. The strong affinity of tantalum (when hot) for oxygen, makes it necessary to heat tantalum steel under special conditions that will prevent contact of the heated steel with the air. The electric furnace is mostly used for this purpose. Tantalum ores are rare, and ferro-tantalum (the form in which it is used) is costly.

The effective horse-power of a turbine is determined from the formula: $hp. = \eta \times \text{flow of water in lb. per sec. multiplied by head in feet divided by } 550$, where η is the efficiency coefficient, which varies according to the size and type of turbine. A formula which is based on the relations existing between the head, revolutions of the wheel and the horse-power is: $\phi = \gamma \sqrt{hp./H^{1.5}}$, in which γ = revolutions per minute, H = head in feet, and $hp.$ the theoretical horse-power. From many tests of wheels there has been derived the accompanying table, which gives the proper values of η in per cent of the theoretical efficiency for the corresponding values of ϕ :

ϕ	5	10	15	20
η	78.5	80.8	83.2	84.1
ϕ	25	30	35	40
η	83	81.8	80.6	79.5
ϕ	45	50	55	
η	78.7	77	75.8	

ORES FORMED BY MAGMATIC SEGREGATION

Written for the MINING AND SCIENTIFIC PRESS
By F. LYNWOOD GARRISON.

Ores of this character may be defined as aggregations of metals and metallic compounds occurring in, or having their origin in, constituents of the igneous or eruptive rocks in which the deposit is found. The fact that eruptive rocks contain metals in various forms is now generally recognized. The old idea of an 'indefinite below' as their primal source appears to be giving place to more logical theories. Moreover, the hypothesis of magmatic differentiation of the rocks themselves from a parent magma is now quite generally accepted by geologists. Thus, for example, it has been claimed in the Tonopah district, Nevada, that the original magma was split by differentiation, first into basic andesite ('later andesite') and silicious dacite, and by a later continuation of the process, into rhyolite and basalt. It is logical to suppose that further operation of the process may produce metallic segregations in the eruptives, sometimes of sufficient magnitude to be of commercial importance.

Some geologists attempt to distinguish between differentiations or segregations which have developed within the laccolith, that is, a magma at or near the surface of the earth, and such as have taken place in the magma when deep-seated, and afterward carried upward by a separate act of eruption. The general conception as to what constitutes a magma appears to be vague. It is ordinarily defined as a molten or plastic material lying beneath the surface of the earth, that is, igneous rock in an unconsolidated or unindividualized condition; it may be in fact regarded as essentially a solution. Van Hise considers that under certain conditions of heat and pressure solids and liquids are miscible, that is, a magma can be at the same locality several different things, varying with the depth and the pressure. Near the surface it may be an intensely heated molten rock-mass holding water in solution, and at greater depths an intensely heated solvent holding rock in solution. Conceived in this way, it is possible to suppose a slowly cooling mass in which minerals and metals can arrange themselves according to Soret's principle, and at the same time we may assume the pressure of the solvents as strong enough to remove or replace certain minerals and to impregnate their skeletons with sulphides, as shown by sections examined microscopically.¹ The forces regulating magmatic differentiation and segregation are obscure, and have not been extensively investigated. Soret's principle may account for some abstruse conditions, since, according to this law, dissolved matter is concentrated in the coolest part of the solution; in other words, molecular concentration may be caused by differences of temperature in a homogeneous solution unequally heated, and concentration will be greatest in the section of lowest temperature. The operation of this law depends upon the fact that rapidity of diffusion is directly proportional to the

temperature, and is greater at high than at low heats. Some geologists take the view that a magma may be regarded as a mixture of different liquids, partly insoluble in one another, and that this principle of limited solubility must be considered as a physico-chemical principle governing the differentiation phenomena of silicate magmas in general.

According to Becker,² and Harker,³ molecular flow in cooling magmas is too slow in its operation to cause magmatic differentiation. Both Becker⁴ and Spurr⁵ contend that the migration and concentration of the first crop of heavy minerals near the borders is to a great extent due to convection currents, resulting from differences of temperature. Park⁶ does not consider these hypotheses quite satisfactory, for he contends that in a molten magma confined between walls the direction of the convection currents in its central portion would be upward and outward, and in the outer sections they would be downward and inward. Consequently this cycle of flow would be as likely to form central as border aggregations, or segregations only in the outer limits of the magma. Convection currents, even in a very fluid magma, are slow, except there be a constant accession of heat from below in amount much larger than that which would be normal to the depth. Park believes that there is no evidence of such accession in the case of a magmatic mass forming either a dike or a laccolith. He believes that border-segregation is mainly due to differences of osmotic pressure in the magma, with convection currents perhaps acting as a contributory force.

Osmotic pressure is commonly defined as a force causing an impulse or tendency of fluids to pass through partitions and to mix or become diffused through each other. There can be no doubt that molten rock-magmas are unstable, and tend to break up into more or less distinctly separate magmas, with sharp contrasts in their percentages of silica and base. In other words, as a result of diffusion and differentiation, the original homogeneous molten mass splits into a number of sub-magmas. Hence in one and the same eruptive district, instead of a single form of rock with a constant chemical character we find a number of rocks of varying composition, yet having a family resemblance to the parent type. Prolonged high temperature acting upon a mixed mass of material may furnish conditions suitable for slow aggregation and crystalline re-arrangement, without the melting point being attained. Hundeshagen⁷ observed that, in the Dutch East Indies, certain basic diorites appear to form the outer crust of batholiths of granite, and are not due to later eruptions, thus confirming what has been repeatedly observed in other parts of the world, namely, that igneous rocks are often more basic in their outer portions than within the mass. The outer portions of these granites are usually richer in the heavier minerals, such

as magnetite and hornblende, than are the inner portions.

Sjögren⁸ mentions the remarkable fact that in most of the Scandinavian iron ore deposits of segregative origin, notably at Taberg, the orebody forms the kernel of the mountain, that is, the ore concentration occupies the central parts of the eruptive mass. This is in sharp contrast to the concentrations of the basic constituents of eruptive rocks along the edges or borders of the mass. The concentration of magnesia has taken place, not so much in the ore, as in the concentration-facies between the normal rock and the segregations richest in iron. It manifests itself in the formation of magnesian iron silicates of the olivine and pyroxene groups. A certain percentage of magnesia is found even in the purest segregations of ilmenite in labradorite rock, owing to a mixture with $MgTiO_2$. The alumina left in the final concentrates combines particularly with the magnesia, forming spinel, the creation of which is favored by the relative deficiency of silica in the magma. Attention is also called to the fact that the magnesia-content increases in the first stage of concentration and then diminishes. Although the original magma contains more Al_2O_3 than MgO , the case is reversed in the earlier stages of concentration; in the final product, however, alumina again exceeds the magnesia. It is also to be noted that the chromium and vanadium in these rocks has undergone concentration, while the phosphorus appears not to be so affected to a noteworthy degree. That silica, lime, and the alkalis occur in smaller quantities in the concentrates than in the rock mass, is manifested by the total absence of feldspars from these concentrates. Dikes are frequently more basic, or lower in silica, at the edge than in the centre. During crystallization the metallic base is moved to the coldest portion. Kemp⁹ compares these changes to the varying values from the outside to the inside in a solidified ingot of base bullion, and to the variations in chilled pots of copper-nickel-iron mattes. Spurr¹⁰ has repeatedly called attention to the tendency of molten magmas to segregate their highly silicious constituents, and ascribes the origin of pegmatites and quartz veins to this force, the one passing by gradual transitions into the other. The more basic constituents crystallize out first, the process continuing until a sort of acid mother-liquor is left, which eventually crystallizes into pegmatite, aplite (alaskite), and quartz, the least silicious solidifying first, the pure quartz being the last. Spurr's view is that the molten material from which silicious rocks solidify contains more water than do the basic magmas. Therefore, by progressive separation of the more basic constituents, the residual portion of the molten mass becomes more aqueous and more silicious. This would explain the coarse crystallization of pegmatite, which in turn, by the disappearance of feldspar and mica, grades into pure quartz. These rocks show by their structure that they have been deposited from solutions so

attenuated they may be considered as highly heated waters with mineral matter in solution. Associated with this water are quantities of highly mobile and solvent elements, such as fluorine, boron, and chlorine, the presence of which in granite and pegmatite is shown by the resulting tourmaline, mica, and apatite; there may also be present valuable metals, which constitute a large proportion of the whole amount contained in the original magma. Spurr's theory assumes that metal-bearing fluids from which most ore deposits are precipitated, must be extreme differentiation-phases of rock-magmas, and that most ore deposits and mineral veins represent one or the other of the extreme products of magmatic differentiation.

Emmons¹¹ doubts whether igneous magmas as they come from the interior of the earth contain sufficient water to produce these phenomena. Suess¹², on the other hand, takes the affirmative side of the question, dividing hot springs into those in which the waters rise under hydrostatic pressure and those deriving their waters from the interior of the earth, the latter being characterized by intermittence. Kemp¹³ takes a view similar to Suess. Scheerer¹⁴, in advocating an aqueo-igneous origin for granite, suggested that owing to the presence of water the magma might cool considerably below the temperature necessary for solidification under conditions of dry fusion, and thus allow minerals which cannot endure high temperatures to crystallize ahead of the less fusible constituents. One of the most conspicuous of such minerals is allanite, an iron silicate of the rare earths cerium, lanthanum, yttrium, didymium, and erbium. It was for a long time considered one of the most infrequent rock-forming minerals, but is now known to be widely distributed, and is sometimes an important accessory. As this mineral cannot stand a temperature above dull-red heat without change of physical character, it was supposed that its presence was conclusive evidence against the igneous origin of a rock. Epidote was also formerly regarded as a secondary mineral, whereas it is now believed to often originate in igneous rocks. Thus, for example, it is now regarded as an original constituent of certain granites in Maryland, where it occurs in parallel intergrowths with allanite.¹⁵ Epidote, regarded as primary in character, has been noted by Lacroix (*Bull. Soc. Min. de France*, XII, p. 139) in certain rocks from Finistère, France, and by Brogger (*Zeitsch. f. Kryst.*, XVI, p. 99) in pegmatites from Arendal, Norway. Allanite and epidote are representatives of a large number of metalliferous and non-metalliferous substances which enter into the constitution of igneous rocks. They indicate how widely metal-bearing components may occur, and how differently they may be found without being of extraneous origin. They also occur as primary minerals under conditions far more ex-

traordinary and seemingly impossible than those under which many metallic salts are found.

At this point it is desirable to direct attention to the fact that magmatic segregation and differentiation must necessarily take place before solidification, and that ore deposits derived from the same magma after solidification are not segregations, no matter how they occur. It is reasonable to assume that there may be an intermediate stage, wherein the metallic minerals and metals are attacked by aqueous and other gases before the solidification of the magma, and thus be transported to neighboring solidified rocks to be deposited in them as replacements of the rock itself, or in fissures and cavities that have resulted from earth movements which took place long after the consolidation of the particular magma of which it was a part. Of course, such deposits need not necessarily be confined to eruptive rocks, since the metal-bearing solutions and gases could similarly deposit their burden in the cracks and fissures of sedimentary rocks. It is conceivable that after the solidification of the magmas the metallic segregations therein may be dissolved and leached by waters which would transport the metals in solution to the cracks and crevices in the same or in adjacent rocks, and, upon encountering suitable precipitating conditions, deposit the burden therein. It is evident that this kind of circulation, solution, and precipitation may continue indefinitely as long as water is present in the rocks. The ore deposits thus created cannot well be distinguished from those formed by gaseous emanations; probably in most instances both classes of phenomena act to produce fissure veins and lodes as we now find them. Such deposits, however, are not in any sense segregations, and are only mentioned incidentally, although they are undoubtedly the sources of our most commercially valuable orebodies. Magmatic segregation may have been the first step in their creation, but if the process had stopped at that point, such deposits would probably be too lean or too small to be of importance; experience has shown that in comparatively few instances are primal magmatic segregations of sufficient size or richness to be of economic value. By reason of magmatic differentiation or segregation, some portions of an eruptive are richer in metals than the average of the mass, in other words, magmatic concentration may assemble the metallic minerals in certain definite areas of the rock or magma. Circulating solutions can subsequently abstract these metallic stores, transporting them to other localities where favorable conditions for re-deposition are present, and thus the ordinary and usual form of mineral fissure veins or lodes, which may or may not be further enriched by secondary solution and precipitation of minerals from the upper portion of the lode itself or neighboring deposits.

It is evident that this process of accretion may be repeated many times, which would account, in part at least, for the extraordinarily rich bunches of ore sometimes encountered in veins.

While it is plain that magmatic segregation may assemble metallic minerals in certain circumscribed areas, it does not follow that they are likely to be of

sufficient size or richness to constitute ore deposits. Whether a rock is an ore or not depends obviously upon the cost of treatment necessary to extract the metal from it. It seems probable, therefore, that we have in magmas, just as in the vadose circulation, solution and segregation repeated a sufficient number of times to cause an accretion in metallic minerals of a size large enough to form an orebody in a commercial sense. It must be admitted that in both cases much must be left to the conception of the investigator, but only by such deductive reasoning can we ever hope to arrive at a logical working hypothesis regarding these difficult but extremely important matters.

Another factor which plays an important rôle in the accumulation of ore deposits by both magmatic processes and by vadose circulation, is that of magmatic waters. In a highly heated mass, this water must be in the dissociated form, that is, as hydrogen and oxygen, and must be under a high pressure. There is as yet nothing known to indicate how these gases will act upon metallic minerals. Probably with other gases, notably hydrochloric acid, the action would be energetic, as vehicles for the transportation of both minerals and gangue. The ease of such circulation through the magmatic mass is of course greatest while the rock is entirely molten, and will gradually cease as the mass cools and hardens. In this connection Kemp¹⁷ points out that even the crystallization of the rock-forming minerals may be occasioned by the loss of dissolved gases. As the mass congeals the gas bubbles will be more and more hindered in their egress, consequently will attempt to depart along cracks, crevices, and openings. As compared with relatively cold meteoric waters which may later penetrate the rock, the solvent and corroding action of these gases is probably thorough and far-reaching. As far as the leaching action is concerned, the general relation of crevices to the mass must be much the same for both. Kemp observes that the presence of metals in igneous rocks, as shown by assay, proves that all the original contents have not been taken away by either process. He believes an igneous mass may be considered as the source of the magmatic water, even if not of the ores and gangue, and a well established, highly heated reservoir for this solvent is thus provided, at the necessary depths within the earth. Evidently such water takes metals as well as gangue from the parent mass and from the overlying rocks traversed by it. In the upward journey, meteoric waters may mingle with the magmatic, and as temperatures and pressures fall, a precipitation of the dissolved burden takes place, and orebodies are believed to be the result. Gradually the source of the water and its store of energy becomes exhausted, circulation dies out, the period of vein-formation ceases, and the secondary concentration or enrichment through the agency of meteoric waters remains as the only influence to change the character of the ore deposits.

Magmatic segregation is evidently a primary pro-

¹⁷*Scientific American, Supplement, No. 1670, pp. 10 and 11 (Jan. 1908).* (Presidential Address before N. Y. Academy of Sciences.)

cess, the first phase of a long system of change; its study is therefore of the greatest importance, although surrounded as it is by so many difficulties and obscurities. The theory that all igneous magmas contain water and dissolved metals which, upon ascent of the magma into a zone of lessening pressure, are given off, penetrate the surrounding rocks, and ascend to the surface as thermal springs, is being received with general favor. The results of such action Lindgren¹⁸ classifies as follows, in consecutive order: (1) product of igneous differentiation in the magmas; (2) contact deposits at the point where the volatile substances left the magma; (3) deposits by magmatic waters on their way to the surface at greater or less distance from their point of origin and more or less mixed with surface waters.

Ore deposits derived from magmatic segregation may for convenience be divided into three general groups: (A) native metals, such as gold, platinum, rarely copper, and possibly silver; (B) metallic oxides; (C) sulphides and arsenides. It has moreover been observed that some classes of metallic minerals favor certain rocks, thus titaniferous iron ores are mostly in basic eruptives, such as diabase; chromic iron, nickel, and platinum minerals favor peridotites and their serpentine derivatives; nickeliferous pyrrhotites usually occur in gabbro; and tin oxide is almost invariably found in granitic rocks. It is probable that these various classes of inorganic natural selection may be due to one or the other of two distinct processes of origin. First, by mass-action, and second, by vapors due to aqueous vapor above the critical temperature, that is, the action or force known as pneumatolytic, a process operating subsequently to eruption. By virtue of its direct genetic connection with eruptive conditions, it may be classed as allied to magmatic deposits. By mass-action it has been observed that the heavy minerals concentrate in the bottom of a horizontal eruptive sheet, sinking before the molten mass chills or becomes plastic. This action is chiefly due to the force of gravity, and to some extent to the Gouy and Chaperon's principle, according to which the bases tend to collect toward the outer margin, while the central portion is higher in silica. Sulphides to some extent aggregate in obedience to the law of mutual attraction. There may be a gradual transition from rock carrying little ore to ore containing little rock. Basic (dioritic) rocks gradually merge into acid or granitic rocks. Regarded in the light of experience with furnace slags, acid rocks are those which would naturally chill and solidify first, hence diorites and norites, being highly basic and fusible, would be the last to separate from rock masses. Metallic sulphides tend toward segregation in the basic portions of the magma away from the acid. A fused magma is essentially a solution of a number of different oxides and sulphides. In cooling, the least soluble constituents separate first and tend to concentrate in the coolest portions of the magma, which is usually along the borders of the mass. In an elliptical mass the ends tend to cool most rapidly and the least fusible min-

erals to assemble and become localized in favorable spots at the expense of other portions of the wall-space. As a rule ferro-magnesian silicates are richer in metals than the other portions of a magma; the metals appear to exist in them either as bases or as metallic inclusions. The escape of sulphurous gases through still molten rock near contacts, tends to produce metallic sulphides wherever they encounter the metals, even though the general conditions of the mass are oxidizing. Such sulphides would evidently be formed in the order of their affinity for sulphur; iron first, then copper, nickel, and so on. It is not difficult to imagine this process taking place in a molten intrusive closely confined by relatively cool rock; the emanating gases passing upward through the fluid magma and restricted to it by the surrounding rock. This idea harmonizes with experience in finding ore thus restricted to the area of a once fluid intrusion.

Kemp¹⁹ states that as a general rule minute quantities of sulphides disseminated through igneous rocks with which they have ascended from the depths of the earth, constitute the most reasonable source to refer all ores except iron. I would suggest that a portion of the sulphides may have been produced by the action of sulphur gases upon native metals in the magma, and that their action may have taken place not only before but after partial or entire solidification. The probabilities are that both conditions obtain and that the resulting orebodies of metallic sulphides were due to a combination of the two forces. To say that the rarity of native metals (except gold) in eruptive rocks substantiates this theory, would hardly hold, as there is no knowing that they were ever present, or that the metals were not always in the form of sulphides.

Derivatives from the peridotites, or ultra-basic rocks, are naturally accompanied by a large proportion of iron, sometimes sufficiently great to constitute an iron ore of commercial importance. A notable example of this kind has recently been developed at Mayari, on the north coast of Cuba, 12 miles south of Nipe bay. Peridotite rocks here appear to be overlaid by serpentine, accompanied by diabasic intrusives. The weathering of the peridotites has resulted in accumulations of large areas of ferruginous material resembling the laterite of India and other tropical countries. Laterite may be described as a kind of nodular ferruginous concretion, formed by the damp heat and decomposing vegetation of tropical countries acting upon basic rocks, especially altered peridotites (serpentine). In India there are several varieties of this material, each having a somewhat different origin. The vesicular or pelletal laterite, the class here considered, is formed by the decomposition of the rock in place, and has usually the highest percentage of iron. Whether this material has resulted directly from the alteration of pre-existing iron segregations or is simply the result of a change in the usual rock minerals, has not yet been determined.

The Mayari deposits have so far not been scien-

tifically described. They are referred to in the Hayes-Vaughn-Spencer reconnaissance report published in 1901, but their peculiar lateritic character does not seem to have been recognized. Their average composition from a large number of samples is given as follows:²⁰

	%
Iron	46.03
Silica	5.50
Alumina	10.35
Chromium	1.73
Phosphorus	0.015
Hygrosopic water	31.63
Combined water	13.63

These ores are said to contain some nickel, which seems probable, considering their origin. They occur in a mantle of thick red clay, from which they will probably have to be washed, although from the description published in the *Iron Age* it is not so stated. Similar deposits exist elsewhere in Cuba, and I have seen something resembling them in Santo Domingo. If found in large quantities in the Greater Antillean Islands they are likely to become an important source of ore-supply for the iron and steel works of the Atlantic seaboard.

Resuming the original subject of this paper, it appears, by reviewing the literature, that the number of workable iron deposits scattered throughout the world the origin of which is probably due to magmatic segregation, is large, especially if the titaniferous ores as a class should be included. It has been repeatedly observed that titaniferous iron ore usually occurs in basic rocks, and that the magnetite of the granites and syenites itself carries no titanium, the little which is formed, often to the extent of 1% or more, being in the form of titanite; the titanium having combined with lime and silica from the body of the magma. With basic magmas the silica has been entirely taken up by the feldspars and ferro-magnesian constituents; the titanium has consequently united with the iron and has become concentrated into orebodies by segregation. This rule may perhaps have exceptions, but the consensus of opinion is to the effect that the magnetites of the basic rocks are always titaniferous. Ball²¹ regards the titaniferous iron ores and anorthosite of Iron Mountain, Wyoming, as differentiated products of a common magma, the iron having been intruded into the anorthosite after that rock had completely solidified.

As might be expected from their habit of accompanying basic rocks, vanadium, chromium, nickel, and cobalt are frequently present in titaniferous iron ores. Phosphorus and sulphur are usually present in very small quantities, or they are entirely absent. The division of magnetic ores into non-titaniferous and titaniferous agrees, according to Kemp,²² with their geological relations, the titaniferous being almost always associated with gabbros. The Brazilian deposits and the ores at Alnö in Sweden form exceptions. Here the titaniferous magnetite is usually in the condition of large irregular masses formed by

segregation before or during cooling; sometimes the mineral impregnates the rock.

As previously observed, the presence of a large proportion of iron in meteorites is notable; similarly in terrestrial basic rocks a high percentage of iron is sometimes present. It occurs not only in the dark ferro-magnesian silicates but also as oxides and sulphides. Such rocks may contain as much as 15% of iron oxide, hence it is logical to suppose that from the highly ferruginous phases of ordinary basic rocks it is but a short step to a stage where magnetite by selective segregation becomes the principal constituent. Similarly, chromium, nickel, platinum, and frequently copper, appear to have resulted from such selective segregation in highly basic rocks. In general it may be assumed that magmatic differentiation divides the mass into two principal parts, one grading into the other. At the extreme limit of the basic half workable deposits of the aforesaid metals are apt to be found, while at the other, or silicious extreme, we find the acid granites, aplites (alaskites), pegmatites, and quartz veins, which are often auriferous. Admitting magmatic segregation to be a primary process, the thought arises, cannot some light be thrown on this obscure subject by a study of meteorites and meteoric matter? In this class of material there are, of course, certain compounds that are unstable and unknown in the earth, such as chlorides, sulphides, and phosphides, and also some volatile or combustible hydrocarbons. The absence from meteoric material of quartz, feldspars, micas, amphiboles, leucite, and nephelite is notable, and even more so the entire lack of water and hydrates. Unless, therefore, we assume the earth to have been without a hydrosphere and atmosphere at the time of the formation of what we may call the primary rocks, it is difficult to see how similar conditions could exist in these two classes of cosmical bodies, that is, the earth and the meteorites. It is evident, from even a casual study of meteoric material, that segregations of nickeliferous iron have taken place in them and that in many cases this alloy constitutes the bulk of the meteorite. We have no evidence that primary magmas in the earth are homogeneous; the heterogeneity of meteorites is well known, and argues that cosmic material is far from homogeneous. But meteorites vary greatly in this respect, and are evidently polygenic, some having a tuffaceous structure, while others are of so uniform a character that crystallization from a single magma is indicated.

One of the most striking differences between terrestrial rocks and meteoric stone is the absence of silica and water in the meteorites. To assume that the primal rocks in the earth were of similar origin to meteorites, some plausible theory must be found to account for the absence of the quartz and water in the meteorites. Farrington²³ has undertaken this in the following way: "The free silica in the earth's crust is readily accounted for if we remember that the rocks of the earth's crust have been worked over, while in meteorites they are seen in their primitive condition. When silicates are exposed to the action

²³*Journal of Geology*, Vol. IX (1901), p. 631.

of CO_2 for any length of time the bases change to carbonates and silica is set free."²⁴ "It seems reasonable to suppose that the vast amount of calcium and magnesium now held in limestone, was originally in the form of silicates. If the CO_2 of the limestones should be withdrawn to the atmosphere, and their bases combined with the excess in silica of the crust, rocks as basic as those in meteorites would probably be formed. The lack of oxygen in meteorites may only be relative, because much of the matter of which they are composed was in the interior, deep-seated, and protected from gaseous action. The superficial lighter silicious portions of meteorites are found to be oxidized. It is reasonable to believe that the earth's substance is not oxidized except in its superficial crust." The rocks of the earth do not seem to have the power of absorbing and holding oxygen as they do other gases. Terrestrial rocks do not contain it, although they hold hydrogen, carbon dioxide, and carbon monoxide in large quantities. The absence of water from the meteorites is an important gap in the parallelism. In the gases hydrogen and oxygen, which meteorites possess, the cosmic body has the elements necessary for the formation of water. The chief reason for the absence of water from meteorites seems to be the fact that the size of the meteoric spheroid was probably not sufficient to enable it to hold a quantity of the free gases competent to the formation of water, or even to retain water-vapor if once formed. The presence in some meteorites of large proportions of the basic silicate minerals, olivine, enstatite, and diopside, is notable. A meteorite from Carcote, in Chile, described by Sandberger,²⁵ contained 33.83 CaO, 8.40 MgO, and 30.25% KCl, etc. Kislakowsky²⁶ describes a meteorite containing over 8% of the silicate anorthite ($\text{CaAl}_2\text{Si}_2\text{O}_8$). Iron sulphide is also of frequent occurrence in meteorites in a peculiar form, which has been given the definite name of troilite. It closely resembles pyrrhotite. Common iron pyrite has also been observed in a number of instances. It is evident, therefore, that there are fundamental resemblances between certain kinds of meteoric material and some of our basic rocks. Even if the planetismal hypothesis be accepted, we are not justified in assuming that our present basic rocks represent the primordial material from which eruptive and extrusive rocks in general were differentiated. That all such rocks as we now know are phases of an original approximately homogeneous magma is a postulate which appears to be meeting with general acceptance by advanced geologists.

The density of the earth is perfectly consistent with the planetismal hypothesis of Chamberlin; which is, in brief, that the earth was originally an aggregation of meteoric material. Even some of the stony meteorites are brecciated, showing that they are probably built up from fragments of larger bodies. Some students assume that stony meteorites correspond in both composition and structure to the

comparatively shallow fracture-zone of the earth, while the nickel-iron phase represents the barysphere, or heavy core, beneath the crust. There is no evidence that the primary magma of the earth was homogeneous; on the contrary, if we accept the planetismal hypothesis, the well known heterogeneity of meteorites would tend to indicate that cosmic materials are far from uniform or homogeneous in character.

CONTINGENT FEES.

At a recent meeting of the New York section of the Mining and Metallurgical Society of America the following expressions of opinion were submitted:

F. F. Sharpless.—When the present question was proposed for discussion at the meeting of January 14, it brought quick and positive answers, but as discussion progressed it became evident that the positive answers needed modifying clauses. On giving the subject a little careful consideration it becomes evident that there are occasions when a contingent fee is highly proper and other occasions when one is equally improper. But, before trying to classify these it is advisable to define what is meant by a contingent fee. The Century dictionary definition of contingent as applied to fees is unsatisfactory, and it is doubtful if a definition can be formulated which will cover the point to the entire satisfaction of all our members.

Subject to modification, I would suggest that contingent fee is a remuneration in which time and amount depend upon the actual or anticipated success of the business resulting from the services for which the fee is rendered.

This definition apparently covers all kinds of contingent fees that were specifically mentioned in the sundry examples spoken of during the discussion; it includes that fee which is proposed as a bribe in order to get a highly colored report on a questionable undertaking, as well as an unpromised honorarium given to an employee for exceptional services well performed.

At first thought 'contingent fee' suggests a bribe. We immediately think of someone offering us a fee of large amount for a report on a property, provided the report is favorable, but the 'someone' can pay only a small amount if the report be unfavorable. There is no doubt in the mind of any member of the Society what should be our stand in respect to a bribe, and it seems superfluous that the members should even take a vote or go on record in regard to anything so obviously immoral.

Carrying the thought to the opposite extreme, we see that an honorarium is a fee paid contingent upon the results of exceptional advice or services rendered of some kind, but it too must be included in the above definition. In this case also I think our members are all of a mind as to the wisdom of accepting or giving a contingent fee. It can do no harm morally or otherwise to the recipient or donor, it is a mark of appreciation for services rendered and it may be considered as fully earned, and further it is a fee that could have been earned in no other manner. It is a merited reward for the use of brains.

Between these two extremes there are contingent fees of many types, many individual cases were pointed out, and we can think of many more that are supposable, differing from each other to such slight extent that they can scarcely be put into classes. They shade from the true reward for honest services, by almost imperceptible differences, to the bribe for a misstatement of facts.

A type of contingent fee that is common at the

present time, both in the United States and abroad, contemplates the steady employment of capable men under a rather modest fee, with an understanding that they will participate with their employers in the profits of any business resulting from the efforts of the employee. This type of a fee is advantageous to both employer and employed. The employer can keep a greater number of men in the field, cover greater territory, and get in touch with more possible business; good men can accept this kind of a fee and remain in active work with ample reward for successful services, whereas if they felt that they could accept only a stipulated but larger fee they could not be so employed continuously and the larger reward for exceptional services would not be paid. Men whose wide experience and ability are in great demand may not care for such fees, but it scarcely seems that a moral point is involved in the transaction, or that men whose services are in less demand should refuse them.

Fees in the shape of stock interest are sometimes paid, fees that may be regarded as contingent because their value is contingent upon certain eventualities and these will be proper or improper to accept depending upon the conditions under which they are offered and accepted.

The case of an officer, a director or higher official, of a company giving a report to the public as an engineer, was discussed in this connection, it being suggested that the advance in value of stock holdings, promoters' or founders' shares, were a species of contingent fee and that the propriety of such a report could be questioned. It is certain that an officer posing as an engineer and giving information to his stockholders, or to the public, is assuming greater responsibilities than officers of companies usually assume, but if so fortunate that he is capable of doing this it is rather to be commended than discouraged, and the propriety or impropriety of the procedure must be determined by the circumstances of the case.

Almost an endless variety in the forms of contingent fees might be cited, and it seems scarcely possible to lay down a hard and fast rule regarding those that can be classed as proper or improper fees. The conditions surrounding each case, the conditions under each contract, must be understood and appreciated to judge of its propriety.

The questions asked may be answered in a broad way as follows: A contingent fee may be accepted when its acceptance is known of by all parties interested and when it can in no way involve the question of the integrity of the party receiving such fee, and should not be accepted when unknown to any interested party or when the question of integrity can possibly be raised.

While this answer is broad, it will not satisfy many of the instances which may be called to mind, so much depends upon uncertain factors and the personality of the man who makes the decision. In fact, it seems scarcely possible to form a completely satisfactory direct answer to the question. Would it not be better for us to say that in the opinion of this section every engineer must decide for himself in

what circumstances and to what extent he can accept a contingent fee, and must decide when the occasion arises to make a decision? The members of this Society are presumed to be of normal mental capacity and capable of deciding between wrong and right, so that it is superfluous to advise them to be honest. I think it may be taken for granted that every member of the Society will refuse to accept a contingent fee when it is evidently a case of bribe or when his integrity might be questioned by accepting such a fee, and on the other hand, he will be entirely satisfied with his moral position without consulting the Society when he knows that in accepting a contingent fee he has done no possible harm to anyone.

We can be equally sure that when a case arises where there is a possible or probable question of propriety, that the responsible engineer will take the safe path, even though it be to his pecuniary disadvantage, without any suggestions from us. It is equally sure that the irresponsible engineer will take the opposite course, and will do it in spite of any instructions from this Society. In other words, responsible members of this Society will not need a set of rules to guide them on a strictly moral question, and we are not making rules for irresponsible members, for we do not propose to have them of our number.

George C. Stone.—Contingent fees may be divided into two classes. In the first, the conditions under which the fee is to be paid are such that one might reasonably suspect that the judgment of the recipient might be influenced by the prospect or desire of obtaining it. Such fees are obviously improper. Those of the second class are conditional on the results obtained in work—under the supervision and control of the recipient, and are proper. In the first class, if the recipient is influenced in his judgment, statements, or acts, it is possible that such influence may cause injury to someone. In the second class, any influence exerted by the fee cannot possibly injure anyone.

Perhaps the best definition of what contingent fees are permissible and what are not is, if it is possible that the effect of the fee can injure anyone it is not permissible, while if it cannot do injury to anyone it is. This definition seems to me broad enough to cover all cases, and specific enough to be applicable. The whole question is one of morals, and the basis of any system of morals is that acts that are likely to cause injury are not permissible. This is sometimes modified by the question of the greatest good to the greatest number, but this does not affect the present question.

W. R. Ingalls.—It seems to me that we must discriminate between—first, the engineer acting in a consulting capacity in the strictest sense of professional practice, and second, the engineer acting in a declared, known, and recognized partnership or association with a syndicate or company. An engineer acting in the latter way may with perfect propriety receive for his services a conditional or contingent remuneration in any form and manner that he sees fit, his conduct being governed only by the ordinary rules of business honor. This idea of partnership may

be the decisive factor in determining the ethics of this question. There are many cases when the acceptance of a conditional or contingent fee is undoubtedly proper. For example: A (an inventor) may say to B (an engineer), "If you will successfully prosecute my application for a patent, I will give you an interest in it, and obtaining it will promote a company to buy it." B gives services for which his remuneration is dependent upon his accomplishing a certain result, but no one would question the propriety of his doing so. He becomes a partner with A and is entitled to his share of what may be realized from the subsequent promotion. If, however, he should conceal his interest and should make a report for A to use, he would act improperly. Consequently the saving conditions in this case are (1) partnership, and (2) declaration of it. On the other hand the engineer who is acting in a purely consulting capacity ought not to accept a contingent fee. Continuing the same illustration, if A should say to B, "I am negotiating the sale of my patent and want you to make a report upon it; I will pay you a certain amount if the sale is made," it would be manifestly improper for B to do so. B would lack the element of partnership. Even if A should give to B an interest in the patent, B would commit a breach of professional ethics by making a report without declaring his interest. Of course it is not a contingent fee when the engineer is paid immediately in cash, or property equivalent thereof, or with a promise of same that is not conditional upon anything.

J. Volney Lewis.—A contingent interest or profit, whether known technically as a fee or not, is justifiable only when and to such extent as (1) it is fully understood by all interested parties, which in most cases includes the public, or (2) when it is in such form that no personal profit or advantage could possibly accrue from the submission of a biased report.

A professional report whose author is avowedly connected with the enterprise is received by the public in the light of such connection, and will have more or less weight according as the author's reputation for integrity and freedom from bias is more or less firmly established. His professional standing, however, is jeopardized to a far greater extent than if the report had been made in an entirely disinterested capacity, and failure to make good entails a correspondingly severe penalty. In the latter case it merely weakens confidence in his professional judgment, in the former it strikes a blow at his reputation for personal integrity.

The second clause of my opening statement would prohibit the acceptance of any payment, whether a definite sum or a share in the profits, which is contingent on anything but the actual exploitation of the mine. It precludes the acceptance of stock not publicly avowed, unless such stock is placed in trust or otherwise made non-transferable and unprofitable until such time as successful operation is assured. It permits every proper inducement for the engineer to work for the highest success of the mine, but forbids his participation in profits accruing from the sale of the property or financing of the enterprise or from

transactions in the stock market before the mine has been fully established.

Whenever the possibility of profit from a biased report exists at all it will prove a temptation, and therefore a danger, to some, and many will find in it an excuse for the imputation of evil motives when the fact is eventually made known to the public. Such transactions are therefore to be placed in the dubious class in all cases, and should not receive the sanction of the Society.

H. S. Munroe.—The question of the acceptance of a contingent fee or of an interest in a mining property by a mining engineer is one that cannot be covered by any simple rule of conduct, but involves a wide field between the one extreme of a bribe for a favorable report upon a doubtful property, to the other extreme of a legitimate scheme of profit sharing in which the contingent fee takes the form of payment for success in operating mines or works. Between these two extremes we have a large debatable ground with infinite gradations, in which it is difficult to draw a sharp line between doubtful propositions and those which are perfectly right and proper. Possibly the situation may be made clearer by considering a few typical cases.

A contingent fee or interest, which is intended to encourage or reward skilful management of mines or works is a form of profit-sharing by which the engineer cannot be placed in a false position even if he fails, except so far as he assumes some added responsibility as part owner as well as manager.

In an ordinary mine examination for a purchaser, the mining engineer may be considered to act in a judicial capacity and is in a position to give an unbiased and impartial judgment on the value of the property based upon the evidence that may be obtained in his examination. Some engineers decline to put themselves in any other position than this and refuse to make reports for owners of mines or for promoters interested in the sale of mining properties. An engineer reporting for a purchaser may without impropriety accept from him an interest in the property in lieu of all or part of his fee.

On the other hand, an engineer making a report for an owner or promoter, who may desire to sell a property and who wishes to use the engineer's report for the purpose of effecting such a sale, may be equally impartial and unbiased and may not be influenced in the least degree in his examination or report by the interests or desires of his clients. It is to be assumed that this will be true of the majority of mining engineers. Nevertheless an engineer making such a report appears before the public in the position of a paid advocate, aiding the owner or promoter to dispose of the mine, and his report therefore commands less confidence than one made in the interest of a purchaser. If the engineer is known to be a man of integrity and good judgment, his report even in the capacity of a paid advocate may be accepted at its face value. If, however, the expert is unknown or of less reputation, the statements made by him will not be accepted without question and will be assumed to represent only the most favorable view of the situation.

If now we push this illustration one step further and assume that the engineer openly allies himself with the promoter by accepting an interest in the sale of the property, he puts himself distinctly in the advocate class and he can no longer be assumed to occupy a perfectly judicial or impartial attitude. He becomes then a man interested in effecting the sale of the property, but on a perfectly legitimate and proper basis as part owner or promoter. In this position we may assume that the engineer desires to maintain his reputation for integrity and ability and that he will not permit himself to be associated with, nor will he allow his name to be used in, enterprises of a doubtful character. Indeed as a business man this will be forced upon him, as he is likely to injure his reputation by the failure of such enterprises. Such a position is one of great difficulty and demands business and professional qualifications of a high order. An engineer in this position cannot afford to recommend a property unless the risk of failure is practically nil. Such properties are rare.

If we pursue the illustration a step further and assume that the engineer conceals his connection with the company and poses as an independent and unbiased expert, purporting to act for the purchasers rather than for the promoters, or if he uses his reputation to aid in the sale or flotation of doubtful properties, we pass at once into the domain of fraud.

Unfortunately this line is not a sharp one, and it may happen that an engineer will be drawn insensibly into false positions and be led to countenance schemes that are more than doubtful. A report originally made for a purchaser may be used by that purchaser to promote the subsequent sale of the property. The interest which has been given him by the owner or promoter in case he has allied himself with them in a perfectly proper business relation, will not ordinarily give him power to control in any way the subsequent operations at the mine or the manipulations of the stock by others interested with him. This is a risk which is taken by all business men in partnership relations. It is always difficult to be certain of the absolute honesty and integrity of men with whom we may associate ourselves in such relations.

To sum up the matter then, it is clear that the acceptance of any fee or interest in a mining property that is likely to render the opinion of the examining engineer less impartial will tend to lessen the value of such opinion in the mind of the public and may lead him into a false position, if not into association with doubtful or dishonest practices.

Contingent fees are therefore to be judged in every case by the simple test of their effect upon the engineer himself and upon his position with regard to the investing public. If the engineer is placed in a false position in any degree, the contingent fee or interest must be considered as doubtful or dangerous, if not absolutely dishonest.

Aluminum, often used in the manufacture of ordinary steels as a purifier during the making process, does not appear to add any desirable quality to high-speed steel, and so far as can be learned is not much, if at all, used in its manufacture.

COMPANY REPORTS.

The British South Africa Co. has just issued its report for the year ended March 31, 1908, bearing imprint of February 26, 1909. With such deliberation a well-matured statement would seem to be inevitable. The company's position is in fact presented with all the skill of a diplomatic body. This is not to be criticized in a corporation vested with functions of civil administration. It is interesting to note the steps which are steadily trending toward political union with the other South African colonies. The population is growing very slowly, the number having risen from 487,200 in 1901 to 662,800 in 1907, but the increase in wealth per capita has grown enormously. In mining a notable advance has been made. In 1900 the gold output was only £308,249. This grew steadily and rapidly, taking great leaps in 1905 and 1906, until the year 1908 showed a production of £2,526,007. The production of other metals was, silver 729,103 oz., diamonds 7020 carats, copper 220 tons, lead 3630 tons, chrome iron 25,021 tons, wolframite 60 tons, scheelite 40 tons, asbestos 55 tons, antimony 14 tons, zinc ore (coming from northwestern Rhodesia) 13,156 tons, and coal 586,729 tons. This reveals possibilities of a varied mineral industry of the kind suited to large expansion of manufacturing as the country develops. The gold mills operating in Rhodesia contained an aggregate of 1488 stamps, and 5 tube-mills, and the ore crushed amounted to 1,612,453 tons. Tailing treated was 651,326 tons. The total gold recovery from this tonnage was 612,052 oz. The 30% interest of the British South Africa Co. in the shares of mining companies has been abolished, and a royalty on claims working at a profit is substituted. Companies organized in the past are entitled to re-organize under the new regulations. The negotiations for the extension northward of the Rhodesian railway system have been concluded. Arrangements have been made for the construction of the Rhodesian section by a contract with the Tanganyika Concessions, Ltd. This railroad corporation will have the title Rhodesia-Katanga Junction Railway & Mineral Co. Work has already begun. Great activity is anticipated in northwestern Rhodesia when the railroad reaches the Bwana M'Kubwa copper mine. The gross revenue from the existing railroad showed an increase of 18% during 1908. The Company goes bravely on facing continual deficits which the future may redeem. The shortage of revenue over expenditure for the fiscal year under review amounted to £152,889.

PITTSBURG SILVER PEAK.

A report for the year ending December 31, 1908, has been issued by the Pittsburg Silver Peak Gold Mining Co., whose mining property is at Blair, Nevada. William Flinn, of Pittsburg, is president and George T. Oliver is vice-president. The general manager is George O. Bradley, a man of first-rate reputation, whom we do not hold responsible for the character of the report, the defects of which must be debited to the directors. Indeed this annual report is a good example of what such a document should not be. No statement is made of the number of shares in the incorporation, no facts are given as to ore reserves, nor is even a profit and loss statement attached to the meagre accounts. According to the figures given, 105,670 tons of ore were milled in the 12 months, for a yield of \$848,713, out of which \$499,789 is deducted for operating expenses, leaving a profit of \$348,923. The statement of liabilities is confusing, but it is inferred that a net liability exists of \$459,213. With a monthly profit of \$35,000 this will be wiped out in a little over a year. From other sources we learn that the capital of the company is \$3,000,000 in \$1 shares.

MINES COMPANY OF AMERICA.

This report is the first annual statement issued by the company, of which John Lambert, of Chicago, is president and George A. Schroter, of Denver, consulting engineer. The company controls the Creston-Colorado mines at Minas Prietas, in Sonora, Mexico, and also has an interest in the

Dolores, in Chihuahua. The report is not signed and it is an unsatisfactory document as a medium of information to shareholders. While it is stated that "within the past two years costs per ton have been reduced from \$10 to about \$6.50," the financial statement shows that in 1908 the mill crushed 79,200 tons of "rock" at an expense of \$814,820, from which it is obvious that the cost was over \$10 per ton. What is "rock" anyway? From the monthly reports it is apparent that a large part of the material fed into the mill is old tailing, and as this has been already mined and crushed the cost of treatment should be slight, thereby reducing average costs, in a manner that might be misleading without an explanation. For instance, two years ago the ore reserves were estimated at 83,000 tons, since then 140,000 tons have been crushed, and yet the report shows 90,000 tons available. How much of the 140,000 tons was old tailing? According to the report the profits for the year ending September 30, 1908, were \$540,794, while the dividends paid during 1908 aggregated \$600,000. Up to date the company has paid \$3,385,000 in dividends.

LIBERTY BELL.

According to the report for the year ending September 30, 1908, the Liberty Bell Gold Mining Company did well. The president is Arthur Winslow, of Boston, a mining engineer and geologist of high reputation; the local management in Colorado is in the hands of Charles A. Chase, consulting engineer, and Edward H. Nutter, superintendent. The mine is in the high ranges above Telluride, Colorado, and the company is one of the most successful engaged in the exploitation of low-grade gold ore. The report for 1908 shows that an increase of tonnage and a diminution of costs characterized the operations, which were also marked by an improvement in the grade of ore; thus good management was aided by good luck. The Company paid dividends at the rate of 12% on the capital issued.

Proceeding to details, we find that 116,353 tons were milled, at a cost of \$6.07, as against \$6.45 in 1907. The receipts were \$874,428, or \$7.51 per ton, as against \$7.25 in 1907. The profit was \$167,952, or \$1.44 per ton, as against 80 cents in 1907. The cost of mining was \$3.13 per ton, of which 63 cents was for development; tramping cost 36 cents and milling \$1.88. Under milling expenses, we note 4 cents for crushing, 13 cents for concentrating, 25 cents for stamping, 5 cents for amalgamating, 7 cents for re-grinding, 10 cents for settling and agitating, 8 cents for filtering, 8 cents for precipitating, 2 cents for pumping, 37 cents for cyanide, 6 cents for lime, 5 cents for assaying and melting, 3 cents for heating, 2 cents for lighting, 13 cents for depreciation at the rate of 5%, 25 cents for maintenance and repairs, 1 cent for lubricating, 4 cents for tests, 1 cent for watchmen, and 2 cents for superintendence. These many and varied items emphasize the diversity of the processes and apparatus employed in a cyanide plant.

Changes in Foreign Postage.

Changes have been agreed upon in the postal regulations between the United States and foreign countries as follows: between the United States and Australia, the Netherlands, Belgium, and Norway—limit of weight on parcels-post packages, 11 lb.; limit of value, \$80. Rate here for packages to these countries, 12c. for each pound or fraction, and payment is compulsory.

Between the United States and Austria or Italy—limit of value, parcels-post package \$80, instead of \$50, weight limit remaining at 11 pounds.

From Great Britain and Ireland or Germany to the United States—limit of value, parcels-post package, \$80 instead of \$50, weight limit remaining at 11 lb., but parcels not exceeding 11 lb. will be admissible to these countries from the United States, without regard to value.

Letter postage on mail exchanged between the United States and Newfoundland will be 2c. per ounce or fraction thereof; unpaid or short-paid postage to be collected at double rates from the addressees.

MINING AND METALLURGICAL PATENTS.

UNIVERSAL ORE-TREATING FURNACE.—No. 912,394. Chauncey C. Medbery, New York.

A furnace, comprising a cylindrical retaining shell, a refractory lining therefor forming a continuous interior cover for its ends and longitudinal portion constituting a closed ore treating chamber, flues formed in and extending through the refractory lining, means at one end of the chamber for supplying fuel under combustion to some of the flues in the lining, and a discharge opening at the same end of the chamber through which the products of combustion pass from other of the flues.

ELECTROMAGNETIC ORE-SEPARATOR.—No. 912,363. Thomas Charlton, Chicago, Illinois.

In a magnetic ore separator, the combination of a magnetic roll constituting one pole of a magnet, a second magnetic roll constituting another pole of the magnet, means for rotating said rolls in the same direction, the axes of said rolls being arranged in an inclined plane with the adjacent periphery of the upper roll situated over the other and lying in a vertical plane cutting the periphery of the lower roll at a point between the vertical and horizontal diameters of the latter said roll, and means for depositing the material to be separated between the rolls, the rotation of the lower roll with respect to the upper roll being such that the values will be carried by the lower roll away from the upper roll and in upward direction.

METHOD OF SMELTING ORES.—No. 913,655. James T. Carrick, Johannesburg, Transvaal.

In ore smelting processes, the step which consists in burning gaseous or finely comminuted solid fuel under pressure in the reverberatory furnace at the time of tapping the smelting products, and simultaneously checking the draft, whereby flame or heated gas is caused to issue with the smelting products and access of cold air during tapping is prevented.

PROCESS OF OBTAINING NICKEL FROM SILICIOUS ORES.—No. 909,666. Edgar F. Price, Niagara Falls, New York.

The process of producing ferro-nickel, which consists in electrically smelting a charge containing a silicious ore of nickel and iron and carbon, by establishing and maintaining an electric arc within the charge, and surrounding the zone

of reduction and protecting the electrodes from atmospheric oxidation by a considerable body of the charge.

PYRITIC SMELTING.—No. 912,540. James T. Carrick, Johannesburg, Transvaal.

No. 912,540

No. 912,783

In pyritic smelting, the process of producing in the furnace at the base of the focus region of slag formation, a restricted zone having a temperature higher than that of the rest of the furnace by injecting combustible at that point and effecting its combustion within the furnace, for the purpose stated.

APPARATUS FOR SEPARATING ORES BY FLOTATION.—No. 912,783. Auguste J. F. de Bavay, Kew, Victoria, Australia.

In an apparatus of the class described, the combination of a feed pipe, a rotary worm therein, an ore supply connected to each terminal of said pipe, a water supply pipe arranged parallel and adjacent to said feed pipe, a plurality of inclined chutes, distributing means extending transversely of each chute, a liquid containing receptacle at the lower end of each chute, provided at one side with an adjustable overflow lip and inclined gutter for receiving and conveying the particles capable of flotation, an endless traveling belt in each of said receptacles having one end submerged therein and adapted to convey the heavier constituents from one trough to the succeeding inclined chute, spray pipes adapted to deliver water upon the belts after they have emerged from said receptacles, and operating means common to said distributing means and said endless traveling belts.

AGITATING AND SEPARATING MIXTURES OF SOLID MATTER AND LIQUIDS.—No. 912,541. James T. Carrick, Johannesburg, Transvaal.

The process which consists in treating matte with a suitable liquid to generate gas, agitating the mass during digestion by injecting the necessary quantity of said evolved gas into the same, and subsequently drawing off the liquid through a filter medium while maintaining the mass in proximity to the filter in a state of agitation by means of gaseous jets.

Centrifugal Jet-Condenser.

A jet-condenser is recommended for situations where the cooling-water is fresh and suitable for boiler feed, or where a fresh supply of good water can be had. The accompanying illustration shows a Cameron centrifugal jet-condenser arranged to operate in connection with a steam turbine. This arrangement is patented, and was designed to overcome certain difficulties found in other types of jet-condenser sets. The condenser cone is mounted on a tank or hot-well, and is placed on the basement floor underneath the turbine, and directly in line with the turbine exhaust-opening. As the cooling-water flows to the condenser

difficulty there is provided a hot-well in which to submerge the centrifugal pump suction-pipe by carrying it down inside the hot-well to the bottom. The water-level in the hot-well under normal operating conditions is carried at about the centre of the centrifugal pump. Should the quantity of cooling-water be increased, the water-level in the hot-well will rise and result in an increased head on the centrifugal-pump suction and cause the water to flow faster to the centrifugal pump. A decrease in the quantity of cooling-water lowers the level and checks the quantity flowing. The centrifugal pump is therefore self-regulating, having an increased capacity as the water-level in the hot-well rises, and a decreased capacity as it falls. The hot-well provides such storage capacity that these fluctuations in level are in no way violent. A rise and fall of one foot is all that usually occurs. With 28 in. of vacuum in the condenser, the water-level in the hot-well cannot become so low as to uncover the end of the suction-pipe and allow air to get to the centrifugal pump. The injection-spray is regulated by a hand-wheel on the side of the cone, and can be quickly flushed if it become clogged with trash. A vacuum-breaker is provided to prevent the condenser from flooding in case of accidental stopping of the centrifugal pump. This style of condenser is suitable for units from 300 to 8000 kilowatts.

spray-nozzle under suction due to the vacuum, it is essential that the injection-water opening be located not more than 20 ft. above the surface of the water-supply. The incoming steam meets the water-spray, and mingling with it, is condensed and falls into the hot-well, from which it is pumped out by a centrifugal pump. The air and non-condensable vapors are removed by a dry-vacuum pump conveniently situated. In an apparatus of this kind the cooling-water must not flow into the condenser faster than the centrifugal pump can pump it out, or the condenser will flood; nor, on the other hand, should the centrifugal pump empty the condenser so much faster than the cooling-water enters, for if it does, it will be pumping a mixture of water and air and is liable to accumulate air in its impeller and become air-bound, or in other words, lose its suction, in which event the vacuum will be lost. To overcome this

Commercial Paragraphs.

THE MINE & SMELTER SUPPLY Co. will manufacture and place on the market the Huesser assay balance, the invention of Wilfred Huesser of Salt Lake City, Utah.

THE HOLDERMAN PROCESS Co. has made some satisfactory tests of silver-lead-zinc ore from Pioche, Nevada, with the Behrend Dry Concentrator which was installed in their Salt Lake City plant.

THE GENERAL ENGINEERING Co., Salt Lake, has received a contract from the Imlay Mining Co., of Humboldt county, Nevada, for the erection of a complete concentrating plant. The contractors agree to run the plant for a probationary period and turn it over to the owners in complete running order.

THE CHICAGO HOUSE WRECKING Co., Chicago, has just published a new 500-page catalogue, including all sorts of machinery, hardware, rope, pipe, tanks, tanks, lumber, and building material. This concern makes a specialty of procuring its stock in large lots, such for instance as the purchase of complete expositions, and at Sheriff's or Receiver's sales, and hence can sell both new and second-hand goods at exceptionally low prices. This catalogue will be sent to anyone interested.

Catalogues Received.

THE ALLIS-CHALMERS Co., Milwaukee, Wis., in its bulletin No. 1425

presents the line of perforated metal which it is prepared to furnish.

THE JOSEPH DIXON CRUCIBLE Co., Jersey City, N. J., in a small booklet, 'Air Compressor Lubrication', discusses the advantages of graphite over oil for lubrication of air compressors.

THE WESTERN ELECTRIC Co. is distributing a small pamphlet containing six excellent photographs of President Taft using a telephone. The object is, of course, calling attention to Western Electric telephones.

THE KEUFFEL & ESSER Co., Hoboken, N. J., announces that its 1909 catalogue is ready for distribution. This is the 33rd edition of the catalogue of this well known firm, and is the largest yet published. It contains 540 pages and is copiously illustrated. Every user of engineering instruments or drawing materials should have one.

EDITORIAL.

WE TAKE PLEASURE in stating that arrangements are in progress for the publication of a monthly mining magazine in London and in connection with the organization of the MINING AND SCIENTIFIC PRESS. This new magazine will compete with no periodical already in existence because it will perform a service that no existing paper fulfils. The readers of this paper will receive further particulars at an early date.

THE TIDE of migration is turning northward, the mining engineers and managers who came south for the winter are returning to the scene of their labors, with a view to preparing for the summer campaign of 1909. All signs point to a busy time in the Yukon and Alaska.

RESUMPTION of immigration from Europe upon an unprecedented scale betokens a belief that conditions in the United States are improving. Italy is the chief contributor, probably in consequence of the disasters that destroyed several of her southern communities. America is a melting pot of nationalities, and if the product is not all refined gold, most of it is serviceable metal.

SALOME is the name of the latest mining excitement. Rich gold ore is reported to have been found on the western end of the Harenuvar mountains, in Yuma county, Arizona. Prospectors are hastening thither. Instead of John the Baptist's head on a charger, they expect to see chunks of gold in a pan. If the new camp has the temperament of Mary Garden, it ought to prove an interesting locality.

A WORD of warning is always in order, and in the case of entrance into a foreign country for the purpose of making investments it is well to be reminded that unfamiliar conditions will be met, which necessitate the guidance of men acquainted with the local laws and customs. The article by Mr. F. J. H. Merrill on 'Protection of Mexican Investors', appearing in this issue, will serve to point out certain pitfalls that threaten the unwary. These matters do not imply the existence of unusual difficulties, but emphasize the fact that a knowledge of the law in one country will not suffice as a basis for operation in another. The Mexican laws guarantee the security of property-rights as fully and justly as our own. Concerning the mining laws no less an authority than Judge Curtis H. Lindley says, in his 'American Law Relating to Mines', "The existing code of that Republic is a substantial departure from the old order of things, and furnishes the best example of a liberal and progressive system of mining

laws of any which has heretofore been adopted in any country."

WE ARE INFORMED that the gross output of the Goldfield Consolidated mine in March was worth \$1,074,000, of which \$950,000 was profit. We congratulate the management.

IT IS INTERESTING to note that James J. Hill, a Canadian, working mainly in the interest of vast American enterprises which his genius has created, now controls the greatest developed Canadian coalfield through his dominance of the Crows Nest Pass Company. The old board of directors has just resigned and a group that stands for Mr. Hill succeeds to the management. The merely national point of view is absent from a man with such relationships, but the Canadians are evidently in doubt where to class his sympathies. After all, trade is catholic; it has no political prejudices; it is even averred in many quarters that its patriotism is expressed solely toward peace and prosperity.

EXTRAORDINARY developments are being made in the copper mines at Ely, Nevada. The force of abundant capital is awakening the Giroux, which had pursued a halting career for years. Preparations for steam-shovel mining are under way, as well as better shaft-equipment for extracting the high-grade smelting ores from the Alpha mine. Additional prospecting with the churn-drill has revealed a remarkable body of sulphide ore on the Cumberland-Ely, with only 30 feet of overburden. It is thus available at trifling cost by the steam-shovel. This mass of smelting ore is said to be 200 feet thick. Ely is becoming a mightier factor in the copper industry with each passing day. The Steptoe smelter will soon have three mammoth reverberatories in operation, producing 4,000,000 pounds of copper per month.

FROM the report of the proceedings in the House of Assembly of the Nova Scotian legislature, we note that Mr. Wilcox and Mr. Murray gave information concerning the gold mining industry of the Province. In 1908 the average number of men employed in that industry declined to 89, as compared to 292 in 1905. Last year the production of gold was the smallest for any twelve months since 1881. Mr. Wilcox informed his hearers that he could give no reason for this decline; he plaintively mentioned the fact that at the Toronto Exhibition the exhibit from Nova Scotia took a gold medal and a first prize—as if there were any relation between an exhibit of specimens and a prosperous industry. Paraphrasing a local authority, Mr. Wilcox stated that "gold was not a surface metal, but we must follow it to the depths to develop it with any degree of success"—a dictum worthy of a sophomore at a mining school. Then Mr. Wilcox quoted Mr. Faribault, an excellent surveyor and a keen observer, but a sanguine prophet whose vaticinations have not been warranted by the facts in the case. No amount of scientific disquisition explaining why the saddle formations of Nova Scotia ought to be as rich as those of Bendigo will offset the fact that they are not as rich: it is the old

story of geological vision and mining realization. Mining is an industry, not a doctrine; it is based on facts, not on theories. It is sheer waste of time to make comparisons between regions half the world apart. After Mr. Wilcox came the Premier, Mr. Murray, a gentleman who has done his best to stimulate the gold mining of Nova Scotia and has done everything except one thing that would have been better than all the other things that he has done, namely, publish the report prepared for the Government in 1905 by a mining geologist specially engaged for that purpose. Mr. Murray made a long speech, and took nearly as long to offer excuses for the failure to publish that report as if he had read the report itself. According to the Premier, the very plain advice given in that report was unpalatable to those who desired to give a fillip to gold mining in Nova Scotia. It is slightly more than three years since Mr. Murray received the report, and it is apparent that the discouraging tenor of it has been painfully justified. The gentlemen at Halifax have behaved like children.

Alaskan Coal Lands.

Social development in its commercial aspects is tending toward monopoly; this may mean consolidation in the interests of individual aggrandizement or of communistic distribution of benefits, according as it be controlled and administered. In some cases statutes and regulations devised to prevent combinations in restraint of trade may prove in effect to be themselves in restraint of trade. We refer particularly to the law of May 28, 1908, for prohibiting coal-monopoly in Alaska. The matter has been brought to the front through the recent order of Secretary Ballinger, directing land agents of the Department of the Interior in Alaska to make speedy investigation of applications for patents to coal lands located prior to the Act of Congress mentioned, where no fraud is discovered. That there was an effort to secure some tracts of coal lands of workable dimensions in Alaska is well known, but we understand that no such wholesale segregation was contemplated as came near placing the entire Great West at the mercy of the railroads. The law of 1908 limits the area which may be consolidated in Alaska to 2560 acres. To those familiar with coal mining on an economical scale this will appeal as being an inadequate size to admit of undertaking operations on such a basis as to permit of cheap production. The installation must be governed by the prospective life of the enterprise. Even in the crowded districts of Pennsylvania and West Virginia, a mine based upon less than 5000 acres would be looked upon as being handicapped by its relatively short future. This would apply with greater force in a region as remote as Alaska. It has been proposed by the American Mining Congress that the law be amended to grant a consolidation of 5120 acres, which seems reasonable. The Act is a drastic inhibition of consolidation by any pretext or subterfuge. That is right. The resources of the people must be controlled, but the permission to utilize them should be upon terms that encourage development along eco-

nomical lines. It is not conservation of resources to limit exploitation so that waste of the substance is transferred to waste in the cost of producing it.

What's in a Name?

A man is entitled to spell his name as he pleases; owing to the early adoption of reformed spelling by people who were careless, many names of similar origin are spelled differently; further, by reason of the multiplicity of persons bearing the same name, individuals have differentiated themselves by changing the spelling of the family name. As a result there is no rule for spelling names, and some of them look like typographical errors. For instance, Stanley A. Easton, the manager of the Bunker Hill & Sullivan mine, omits the e in Stanley, so that he has frequently thrown discredit on our proof-reader. The James family is numerous and energetic; they are alike in being progressive Cornishmen, but they spell their names differently. There is Alfred James, the cyanide specialist; there is the mining engineer, Tre-wartha-James, who hyphenates the maternal to the paternal cognomen; there is Cordner-James, another able mining engineer; and there is Samuel James, the stockbroker. These four are brothers and the first three of them are in partnership as James Brothers; obviously it ought to be James Brothers & Hyphens. Curtis is not always Curtis; there is J. S. Curtis, the writer of the Survey monograph on Eureka and the prophet of deep-levels on the Rand, but there is also W. B. Courtis. They are not related, but they went to the same school; one of them was designated as "agricultural Curtis" because he had a hoe in his name. We beg pardon, but this is none of ours. In New York there are two well known engineers named Corning; they are second cousins, but the more academic of the two denies close kinship with the other, and yet Christopher Corning and Frederick K. Corning have both done good work as mining engineers, so that it is evident that the family is of good stock. There are many Douglasses and yet there is one Douglas. James Douglas is the father of Walter, now the general manager of the Copper Queen, but he is not related to Theodore Douglas; the last has managed to gain an honorable individuality despite the precedence in copper mining of his celebrated namesake of the Copper Queen. Theodore Dwight is cousin to Arthur S. Dwight; both are nephews of R. W. Raymond. The Secretary of the Institute is not related to Robert M. Raymond of El Oro, although they have the same New England origin. The manager of the El Oro mine was born in New Brunswick, being descended from a loyalist who crossed into Canada at the time of the Revolution; his descendant has restored the balance of citizenship. There are as many Moores in mining as there were in the Alhambra. Charles J. Moore made a name at Leadville and Cripple Creek, but he is not related to George Moore of filter fame. There are two Philip Moores, one of them is the Harvard graduate now in charge of the Mic Mac mines in Nova Scotia, the other is Philip N. Moore, of St. Louis, who has done notable work in dredging for gold in Montana.

There are enough Turners to form a turnverein. H. W. Turner was formerly with the Geological Survey and is a mining geologist; R. Chester Turner was mine manager at Bodie and then at Tonopah; Scott Turner is a Michigan man and was lately on the staff of the MINING AND SCIENTIFIC PRESS. The Munroes are not all spelled alike. Henry Smith Munroe is professor of mining at Columbia, Charles E. Munroe is professor in the Columbian University at Washington, C. H. Munro is a hydraulic mining engineer, now at Nome; H. S. Munroe is a younger man, recently in South America. The Macdonalds are a troublesome lot in an orthographic way, for there are several ways of spelling that Highland name. Bernard, Joseph, M. E., and Parish J. MacDonald are brothers, in order of seniority. M. E. MacDonald has the honor of being an engineer both fore and aft. Richards is a good old fashioned name and is borne by several useful men. Robert W. of the Massachusetts Institute of Technology is classified with 'Ore Dressing'; J. W. Richards of Lehigh is the authority on metallurgical calculations; H. DeC. Richards, of California, has not written any books, but he could. There are many engineers in the Collins family, and they have all 'made good'. The veteran mining authority, J. H. Collins, now in Cornwall, is the father of Henry F. Collins in Spain, of George E. Collins at Denver, and of Edgar A. Collins at Tonopah. Another brother is Bishop of Gibraltar. The brilliant mining engineer Arthur L. Collins, assassinated at Telluride, was one of this family, all of whom have proved the value of inherited instincts, for they are Cornishmen. Walter McDermott, one of the leaders of the profession in London, must not be confounded with C. McDermid, the efficient secretary of the Institution of Mining and Metallurgy. Thomas H. Leggett, now residing at New York, is not related to J. H. Leggett, who also dredges for gold at Oroville. There is also Alexander Leggat, of Butte. The Peirces, Pearces, and Pearses have their own ways of spelling and pronouncing their names: Richard Pearce, the pioneer copper metallurgist, spells his name in the good old-fashioned way: his sons are Harold V. Pearce and Arthur W. Pearce. George W. Peirce, now at Goldfield, pronounces his name like Purse, so might Arthur L. Pearce, that most nomadic of men, but he makes it correspond with Pierce. Then there is S. H. Pearce, of Johannesburg, who has differentiated himself from the miners by his skill as a cyanider. R. J. Frecheville is the elder brother of William. Herbert C. Hoover is the elder brother of Theodore J.; they are sometimes confused with Edward Hooper, because of a former joint connection with Bewick, Moreing & Co. P. R. Bradley is the younger brother of Fred W. E. D. Ingall is not more singular than Walter R. Ingalls, the editor. S. F. Emmons, the geologist, is not related in any way to Stephen H. Emmens, the alchemist. William H. Emmons of the Survey is the nephew of S. F. John A. Church of New York is not related to L. C. Church, of Joplin, but he has a son named John A. Church, Jr., who is now at Guanajuato. The Farishes constitute a notable group. William A. Farish is the elder brother of John B.; both of them have sons in the

profession. George E. Farish, at Mexico City, is the son of John B., while W. A. Farish, Jr., of El Paso, perpetuates his father's name. Fred G. Farish, who is associated with John B., is not a relative, although distantly connected. L. S. Austin, the professor of metallurgy at Houghton, spells his name differently from Peter T. Austen, the chemist, of New York, but he is the brother of T. S. Austin who died recently at El Paso, and he is the father of Arthur W. Austin, now at work in the Anaconda smelter. W. Rowland Cox, of Spurr & Cox, is the son of William J. Cox, manager of the Camp Bird mine, but he is not related to S. Herbert Cox, the professor of mining in London, nor to Thomas Cox, who was at Ely and is now at Cerro de Pasco. And shall we venture to disentangle the Smiths? We confess to a great respect for a Smith who manages to get out from among the "and others" of his family and achieve distinction. It is easy for a De Kalb or a Weatherbe to win individuality, for there are none of the same name, and the other fellow would be eclipsed anyhow, but a Smith has to get out of the ruck before he begins to see daylight. They spell their names variously, but most of them must be pronounced good. We have H. L. Smyth of Harvard, an honor to any family; we have Howard D. Smith of San Francisco, and Frank Clemes Smith, formerly of South Dakota and now at Bisbee, where Franklin W. also resides; we have J. Audley in Queensland and Percy Bosworth in India. Pascal said that a man was a reed, but he was a thinking reed. That describes several of our friends. They spell themselves variously. Thomas T. Read was formerly at Colorado Springs and is now professor of mining in the Imperial University of Tientsin. John A. Reid, a young Californian, has won his spurs as a mining geologist. He spells his name like H. Fielding Reid, of Johns Hopkins University. H. W. Reed, the manager of the Virginus mine, has had much to do with the development of southwestern Colorado. David C. Reed is at Cerro de Pasco. It used to take nine tailors to make a man, but nowadays one Taylor more than suffices to make a mine. John Taylor & Sons, a firm that is the dean of the mining profession, is represented in London by Robert, Frank, Edgar, Henry, and Arthur of that name. F. M. Taylor, of Taylor & Brunton, is known as an ore sampler *par excellence*; Lewis H. Taylor, Jr., of Philadelphia is a mine operator in Mexico and elsewhere. Frederick Anton Eilers, the pioneer of lead smelting, is the father of Karl Eilers of the American Smelting & Refining Co. Henry, Walter B., and Horace Devereux are brothers. W. B.'s sons (William G. and W. B., Jr.) are in partnership with their father. The Rickards are a necessary evil in mining: Thomas Rickard, of London, is the head of the family, being the only survivor of five brothers; his sons are T. A. and Forbes; his brother Reuben left two sons in California, one being Thomas, who is in the machinery business, and the other Edgar. Harold is the son of Alfred Rickard, the youngest brother of the senior Thomas. Pierre de P. Ricketts and L. D. Ricketts are occasionally confused, the doctorate bestowed on both tending to increase the confusion by eliminating a possible difference. They are not re-

lated, but there is a family connection, both being descended from a former governor of Bermuda, who was named Rickard and had his name mis-spelled in the document appointing him. The Nichols and their sons are worthy of record. There is Frank Nichols, recently editor for the Canadian Geological Survey; Asken M. Nicholas, the inventor of filter-presses, now in Australia; Horace G. Nichols, also an expert cyanider and filterer; J. Clayton Nichols, a mining geologist in Colorado; and Ralph Nichols, who is the best known of this clan, formerly manager of the Boulder Perseverance mine, then in charge of the Avino mines, Mexico. William H. Nichols, of the chemical company of that name, is a household word in the metal business of New York. Frank and Hudson H. Nicholson are not related. E. M. and A. B. Rogers are the two sons of A. N. Rogers, a notable figure in the mining history of Gilpin county, Colorado. Both are connected with the North Star mine, in Arizona. Allen H. Rogers is a Boston engineer, now in Chile. The Janins once formed a notable group: Henry has retired and lives in London, Alexis died in 1897, but Louis is still in harness. His son Charles is the partner of Howard Smith. Ross E. Browne is brother-in-law of Charles Hoffman, who is the father of four capable mining engineers: George, Ross, Karl, and John. Louis Metzger married F. W. Bradley's sister and Robert Kinzie is married to the sister of his assistant, E. P. Kennedy. John Hays Hammond, the mining financier of New York, is not related to I. B. Hammond, the machinery manufacturer of Portland, nor to John H. Hammond of Denver. In San Francisco John Hays Hammond and Wendell P. Hammon are occasionally confused by reason of their common interest in gold dredging. J. Nelson Nevius often has his name spelled like the Nevins family. William H. Shockley is cousin of J. H. Shockley; they are sometimes confused. Arnold Hague is the brother of James D. Hague, and Arnold Becker is the nephew of George F. Becker. Horace V. Winchell is the brother of Alexander N., now professor of geology in the University of Wisconsin. Alexander Winchell is an uncle of these men: U. S. Grant is brother-in-law to Horace V. Winchell. Alpheus Williams, the manager of De Beers, is the son of Gardner F., who first systematically developed the Kimberley deposits. Arthur R. Thomas is the son of the late Capt. Josiah. Charles S. Thomas, Jr., is the son of Charles S. Thomas, the celebrated mining lawyer of Denver. Chester A. Thomas is the resident manager for the Yukon Gold Company, and F. F. Thomas is the man who opened up the Gwin mine. Francis A. Thomson, professor in the University of Washington, W. R. Thompson of the Orford Copper Works, and W. B. Thompson, of Wall Street, should be easily distinguished. By the diversity of their pursuits they illustrate the fact that mining needs many talents.

What's in a name? It is the one thing that belongs peculiarly to the individual, differentiating him from all other men. Therefore the least courtesy any of us can do is to spell and pronounce another man's name as he chooses to spell and pronounce it. In this matter he is the sole arbiter.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

HENRY KRUMB is at Globe, Arizona.
BERNARD HILL has gone to British Guiana.
RALPH NICHOLS was at New York recently.
A. CHESTER BEATTY is at San Antonio, Texas.
W. J. SHARWOOD is here from the Homestake.
A. H. WETHEY has returned to Butte from Europe.
W. SPENCER HUTCHINSON, of Boston, is in Jamaica.
EDWARD T. BAILEY is on his way to the East Indies.
R. GILMAN BROWN is on his way to Mukden, Manchuria.
W. F. A. THOMAE has returned to London from Colombia.
J. R. FINLAY is examining mines in Siskiyou county, California.

C. A. THOMAS, manager for the Yukon Gold Co., is on his way to Dawson.

JAMES EARLS is superintendent of the Gold Hunter mine at Mullan, Idaho.

J. POWER HUTCHINS is at Mountain Ranch, Calaveras county, California.

ARTHUR W. STEVENS was in San Francisco, and has returned to Boise, Idaho.

FRANK M. ESTES, Jr., is with the El Oro Mining & Railway Co., at El Oro, Mexico.

CHESTER W. PURINGTON will be in San Francisco on April 10, on his way to Siberia.

F. H. MORLEY, of Denver, is now associated with DOMINIAN & SMITH, of Mexico City.

CLAUDE T. RICE has left New York to take a position at the Marmato mine in Colombia.

EDMUND JUESSEN, of Spokane, will be manager of the Silver Peak mine, in Nevada, on May 1.

CARLOS W. VAN LAW has resigned as general manager for the Guanajuato Reduction & Mines Company.

A. C. LAWSON has been chosen one of the associate editors of *Economic Geology*, in the place of H. Foster Bain, who resigned.

E. H. BENJAMIN has been elected vice-president of the Joshua Hendy Iron Works, succeeding the late RAOU L. CHARTREY.

Obituary.

WALDEMAR ARENS, general manager for the Iron Silver Mining Co., at Leadville, Colorado, died at his home in California gulch, Leadville, on March 23. He succumbed to pneumonia, at the age of 79. A native of Germany, he came to America when a child, and reached Leadville in 1878, so that he was a pioneer in that great mining district, becoming associated with Levi Z. Leiter and William Stevens. He was highly esteemed; his word was as good as his bond; he was an honorable man.

A. P. KENNEDY, manager for the Hillabee Gold Mining Co., in Tallapoosa county, Alabama, was killed by an accident on March 16. While superintending repairs on a power dam, he was crossing in a boat from one side of the pond to the other, and going too near the brink he was carried over backward, being killed instantly by the fall. Born at Camden, Indiana, he was 40 years of age; he was educated at Purdue University, graduating in 1895. In 1897 he went to the Alabama goldfield, and proved himself a most capable engineer.

Dividends.

On April 3 the Bunker Hill & Sullivan Mining & Concentrating Co. pays dividend No. 139, of \$45,000. This makes the amount of dividends paid since January 1, \$255,000, and the total to date \$10,926,000.

General Mining News.

ARIZONA.

PINAL COUNTY.

S. L. Gibson and William Henderson have effected the sale of the mines of the Gibson Copper Co. to a syndicate in Boston for about \$650,000. The mine has been remarkable for producing sulphide ore from grass roots down to the 400-ft. level when signs of exhaustion were indicated. A short time ago, however, a winze struck another body of high-grade copper ore, and soon after, the deal in Boston was consummated.—From Steamboat Rock, to the east of Kelvin, come reports of the discovery of gold ore by J. H. Bates and A. Sears. These two men were grubstaked by S. D. Gardom and Phil Grigsby, of Phoenix.

YAVAPAI COUNTY.

A rich strike of copper sulphide is reported from the Grand Island Copper Co.'s property, five miles south of Jerome. The shaft is 84 ft. deep, and has cut a vein 3 ft. wide.—Diamond drilling has been started at the Sycamore mine on the Verde river near Sycamore creek.

YUMA COUNTY.

John S. Reilly and J. W. Milnes have returned from a visit to the new gold camps near Salome, in the Granite Wash range, and state unconditionally that it is the richest ever made in Arizona. The gold occurs native, commonly in wire form, and is found in a slate schist formation intersected by diorite dikes. The original strike was made by

Parker, Arizona.

Al Alger, Henry Barker, and Herman Griffin, on one of the claims of the Arizona Northern group, but finds are made over a wide area of the schist belt. Although phenomenally rich finds have certainly been made, it must be distinctly remembered that up to the present there is not so much as a 10-ft. hole in the entire region of the discovery.

The Yuma Copper Co. has been organized in Houghton, with Samuel Brady, superintendent of the Michigan mine, as president. John L. Harris, of the Hancock mine, is vice-president, and C. C. Douglas secretary. The capitalization is \$200,000 and is organized under Arizona laws. The property consists of upward of 600 acres of copper lands on the Arizona & California railroad cut-off.

CALIFORNIA.

FRESNO COUNTY.

Talk of a possible railroad into the Minarets region is being renewed as a result of the investigation made by Paul F. Mohr. He found tungsten, iron, and copper ores, while both silver and lead had previously been found by J. W. Drouillard and others. From a scenic point of view the road would be one of the finest in the State.

INYO COUNTY.

(Special Correspondence).—The Treasure Hill Co. is rapidly perfecting arrangements for unwatering and operating the old Tower property. Men are being engaged, and new machinery will soon be installed. W. Gillette Scott is manager.—The 100-ton cyanide plant at the Keane Wonder mine has been placed in commission. It is

expected to add from \$5000 to \$8000 per month to the present output, which is now approximately \$20,000 per month.—At the North Inyo Consolidated property the lower tunnel is being pushed ahead steadily. Several veins of low-grade ore have been encountered. M. T. Stovall is manager.—The Tecopa mines are maintaining large outputs of silver and lead. It is rumored that this company has secured a controlling interest in the Needles smelter, and within a short time will largely augment its working force. The Cerro Gordo mine is maintaining steady shipments of good ore to the Keeler smelter. During the present summer the capacity of the plant will be materially enlarged.—Work continues at the Greenwater Death Valley mine with fairly satisfactory results. The big vein of copper-bearing ore opened on the 1000-ft. level is being developed. The shaft is being sunk to 1500 ft.—Considerable prospecting is being done in Gold valley.

Bishop, March 27.

The Furnace Creek Copper Co., which has been operating in the Greenwater district for the past two and a half years, has finally given up hope, and work has been entirely suspended. James Casey, the last of the employees, will shortly leave the camp.

Clarence A. Beall has taken charge of the Casa Diablo mine and mill. The mill has been re-started, and there is enough ore on hand for more than a month's run.

NEVADA COUNTY.

(Special Correspondence).—A small force of men are working at the old Washington mine, a short distance above the Idaho-Maryland. This is the first time the Washington has been worked for a long term of years.—Operations have been suspended on the Midas and an assessment levied to defray further expenses.—The Black Bear Co. is pushing work on the Forlorn Hope claim. A deal has been closed for several adjoining properties, and a 10-stamp mill has been purchased.—It is reported that a San Francisco company is being formed to operate the Rose Hill mine. The property has been idle for several months, but some work is now being performed by a small crew.—The Dana Co. is arranging for the installation of a hoisting and pumping plant, and later on will erect a stamp-mill. A 7-ft. vein of fair-grade ore is being developed. John Burgess is superintendent. Tonopah people are principally interested.—A lower tunnel is being driven at the Kentucky Ridge mine and is in about 75 ft. It is expected to intersect the lode at considerable depth below the old workings.—Considerable leasing is going on in the Grass Valley and Nevada City districts. Mines that have lain idle for years are being re-opened and worked. This state of affairs is due to the large number of idle men in this section. Many of the lessees are meeting with encouraging success.

Grass Valley, March 29.

Ten additional stamps are being dropped in the Champion mill, making 30 in all. There are also 20 dropping at the Home, on the opposite side of the creek. The ore that is being crushed is being taken out by tributers, of whom there are 54 in the mine. This, with the 26 men on the payroll, makes 80 at work in the Champion properties.—The region around Graniteville is becoming more active. At the Birchville mine a 10-stamp mill is running on ore extracted last year, and a pump has been started to unwater the shaft. Both on the El Oro and the Keller properties development work is being done.

SAN BERNARDINO COUNTY.

Shaft work is being completed at the Oro Belle mine, and the new hoist is doing excellently. In a few days the station on the 100-ft. level will be ready, when cross-cutting and driving will be started. The end-lines of the Oro Belle are contiguous to the property of the Hart Consolidated Co.—Ivanpah is an old silver-producing camp about 24 miles west of Hart, abandoned in the days when silver depreciated in value. The work being done on the Clansman group, lying at the extreme southern end of the camp, is exciting favorable attention. There is a surface showing of 2 ft. of ore, running about 80 oz. silver and development

to the depth of 30 ft. has uncovered a 3-ft. vein of excellent grade. Kewanee, a new gold camp, lies about a mile to the south of the Clansman.

SHASTA COUNTY.

The Noble Electric Steel Co.'s smelter is to start work this week at Heroult. Delays in getting to work have occurred so often that it is hoped that this announcement may at last be true.—It is stated that the Mountain Copper Co. contemplates the development of its Hornet claims near Keswick, which are said to contain more than 5,000,000 tons of ore which will average about 1¾% copper. The management is planning the development of this big deposit by the caving system, and will probably build a new plant to treat this low-grade ore.—The report that the First National Copper Co. is restricting operations is declared by Thomas J. Barbour, the vice-president, to be untrue. It is shipping 600 tons of ore per day to its smelter, or sufficient to maintain its mine and smelter organization of 500 men. However, he says that there is no intention of producing more than 1,000,000 lb. monthly under present conditions of the copper market.—Austin Brown, formerly general manager of the Trinity, has recently made an examination of the properties, accumulating data for a comprehensive report on the present status of the mine. Meanwhile the Trinity property remains shut down and nothing is being done there.

TUOLUMNE COUNTY.

It is authoritatively asserted that operations will shortly be resumed at the property of the United Mines Corporation. It is situated east of Tuolumne, and consists of the Dead Horse, Eureka, Grizzly, New Albany, Lady Washington, and other claims. Work ceased at the property a month ago as the result of a dispute. S. A. James of Cleveland has become general manager and will arrive here this week to pay off all indebtedness. J. M. Elmer will continue as superintendent.—The Duffield and Sonora mines, situated near Arastraville, have been bonded to Stephen Lavagnino, and a crew has been put to work. The price to be paid for the property is \$10,200, of which \$500 has been advanced.—A 10-stamp mill has been purchased for the Kavanaugh-Mangante mine, near Jamestown.

TRINITY COUNTY.

It is reported from Trinity Center that the Headlight mine near Carrville has been sold. The mine was once equipped with a cyanide plant, but was burned three or four years ago.—The electrical power-plant at the Bonanza mine, a former Treadwell property, near Trinity Center, has been destroyed by fire.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—E. J. Wilcox, of Denver, general manager of the Waldorf Consolidated M. & M. Co., states that the 125-ton mill near the portal of the Wilcox adit will be doubled in capacity. It is hoped to have the mill ready inside of 90 days. Driving will be started upon the Paymaster, Commonwealth, and Central Indiana veins, while the main bore is to be advanced about 900 ft. to intersect the ninth level of the Stevens mine.—Since the Argentine Central road was constructed, about four years ago, it has never been operated on Sunday. A change will take place this year, however, as a contract has been entered into with the Colorado & Southern whereby the line will be kept open during the entire year. This has been necessitated by the great amount of ore that is being mined in the Argentine district.—A contract has been entered into by the Argentine-Montezuma M. T. & T. Co. for electric power to be furnished by the United Hydro P. & E. Co., of Georgetown, and within 60 days it is believed that the change will be accomplished. It is estimated that a saving of from \$800 to \$1000 per month may be effected.—The Domino M. & M. Co. is employing men to advance the adit No. 2. A vein was passed a few days ago which shows strong mineralization. Driving is to be started for proving the ground. H. Cochran is manager.—A. A. Hayden, of Denver, secretary of the Golden

Glory M. Co., has arrived in camp from Texas. Funds have been provided, and the Golden Glory adit will be continued into Saxon Mtn., while other men will develop the Drummond group of five claims, situated on Columbia Mtn. J. L. Young has been appointed resident manager.—The rough-jigging plant at the Bellevue-Hudson mine has been brought into use again after a temporary close-down of a few weeks, due to lack of water. An average of five tons are being treated each hour.—The Boston vein, owned by the Philadelphia Mining Co., is developing into a good producer. A stope is showing from 16 to 20 in. of solid ore worth \$25 per ton in silver and lead. A big body of mill dirt is being trammed to the Dover mill for concentration. J. W. Boyd, of Idaho Springs, is manager.—The Standard Ore Co. has been incorporated by W. F. Collins and E. Leet, of Idaho Springs, and J. M. Grace, of Denver, with a capitalization of \$250,000. The corporation has secured control of a block of ground at the Shafter mine, Bellevue Mtn., and work has already been put under way.

Georgetown, March 28.

IDAHO.

BLAINE COUNTY.

The Croesus mill is working well, but the grinding capacity has been found inadequate, and is being increased. Other changes will be made so that in a few weeks the mill will work up to its daily capacity of 80 to 100 tons.

IDAHO COUNTY.

The property of the Idlewilde Mining Co. near Elk City is being developed. The adit to tap the orebody at a depth of 250 ft. has advanced 310 ft. The surface of the vein has been thoroughly explored, and at a depth of 30 ft. an 8-ft. vein was found carrying \$25 free-milling ore. The cost to mine the ore is estimated at \$7 per ton. If the adit cuts a good orebody a 10-stamp mill will be erected. George Shell is president, and J. W. McCune secretary.

P. J. Jennings, of Portland, intends to dredge the Gold Seal placer ground, an area of about 400 acres at the confluence of Elk creek and the American river, or about a mile from Elk City. The machine is reported to have been ordered in Milwaukee.

SHOSHONE COUNTY.

(Special Correspondence).—A deal has just been completed by which the controlling interest in the North Fork Consolidated Mining Co. has been bonded to Eastern capitalists for \$250,000. The bond goes into effect May 1. The claims adjoin the Snowstorm mine at Mullan and have been extensively developed. A good showing of ore has been made.—More than 7 ft. of fine chalcopryite is showing in the face of the drift being run from the foot of the shaft in the Horst Powell mine, on the Little North Fork. Over \$8000 have been spent on development work in the last six months. It is expected that regular shipments will be commenced as soon as the extension of the Idaho Northern railroad is completed into that part of the country.—A report of the Acme Consolidated Silver-Lead Co. shows that the present drift is now in about 540 ft., and that bunches of iron carbonate, silver chloride, and lead carbonate have been exposed. The quartzite is said to be thoroughly impregnated with lead, while two feet of blue quartz speckled with iron sulphide and galena shows in the face.—The Star Mining Co. at Mullan has been running a drift along an 18-in. vein of clean shipping ore and a large quantity of milling ore has also been exposed. The ore is the highest grade that has ever been encountered in the mine. It was reported earlier in the season that this mine had been sold to the Federal Mining & Smelting Co., and that it was to be worked through the Morning mine at Mullan, but the truth of this report has never been confirmed.—The 640-ft. 3-compartment raise from the No. 4 to the No. 3 level of the Hercules mine at Burke has been completed. The raise took seven months to complete, and opens a large amount of new stoping ground.—The long tunnel at the Snowstorm mine has again caved in at the same place as before, and the management has determined to drive around the cave to avoid this bad part of the ground. The cave-in affects about 50 ft. The shipments

from the mine have been reduced from 500 to 200 tons per day.—The well-known dispute involving the ownership of the Neversweat lode mining claim at Burke has at last been finally settled, and John Mader's application for title will now be granted. A consignment of new machinery, including a new hoist, has been ordered for the claim, and development will forthwith be continued.—A report issued by the Idora Mining Co. states that 50 ft. of a raise from No. 3 level has so far been completed, and is in clean shipping ore all the way. The raise will be 380 ft. in height to reach the No. 2 level. Additional machinery and concentrators are to be installed this spring.—The Hypotheek mine in the Kingston district has closed down owing to a break in machinery. The shaft is at present 450 ft. deep. An assessment of 5 mills per share is now delinquent.—Charles A. Solberg and H. P. Ward have resigned from the positions of president and secretary, respectively, of the Amador Copper & Gold Mining Co., and their places have been filled by A. T. Ryan and George F. Stoney of this city. At a recent sale of stock for delinquent assessment the company bought in 650,000 shares, and the directors are considering if those who lost their stock may have the opportunity to redeem.

Wallace, March 27.

An inrush of water has stopped work in the shaft of the Caledonia mine. An electric pump of 75 gal. a minute against a 500-ft. head will be installed, and sinking will then be resumed. Meanwhile driving on the vein is being continued and the silver-lead ore is being stored at the rate of about 50 sacks a day. The company has on hand several carloads of ore for shipment, which are being held awaiting better market conditions.—The miners of the Government Gulch Mining Co.'s property have broken into solid galena ore in the drift run from the 100-ft. level of the shaft. The claims of the company adjoin the Federal and the Stewart mines.

MICHIGAN.

The Isle Royale Copper Co. crushed 218,940 tons of 'rock' in the year, yielding 13.8 lb. copper per ton, or a decrease of 1.4 lb. The mine has been worked principally to improve development, as is shown by the large expense item of \$309,500 for construction. The cost of the copper per pound at the mine was 16.91c., which is further brought up to 28.99c. when construction and smelting are included.—Adventure has temporarily ceased diamond-drill operations owing to an accident to the diamond-drill outfit. The machine was engaged in sinking a hole to further test the lodes discovered during the past year, and had reached a depth of 1600 ft.—Seneca is engaged in drifting on the 200-ft. level in an endeavor to find the main body of the Kearsarge lode.—James MacNaughton, general manager of Calumet & Hecla, left yesterday for Old Point Comfort to recuperate from his recent illness. Most of his work will devolve upon William Uren, who will continue as assistant to the general manager.

MONTANA.

LEWIS AND CLARK COUNTY.

Confirmation of an important strike of copper-bearing ore on the Wolf Creek Mining Co.'s property is made by C. E. Russell, the manager of the property, who says that the orebody cut at a point 200 ft. below the apex of the vein is 4 ft. wide. The face of the main adit, 447 ft. long, is in good ore. Samples of the entire vein assayed \$71 per ton based on 12½c. copper, while picked specimens ran more than 40% copper. The company is a Spokane corporation, most of the stock being held in Washington and Montana. T. G. Cooper is president, C. E. Russell is vice-president and manager, and R. E. Vincent is secretary and treasurer.

MISSOULA COUNTY.

Operations at the Monitor copper mine, about 4 miles south of Salt Lake, have been suspended owing to the heavy snows and lack of fuel. The snow is now over 12 ft. deep. O. H. Linn is superintendent.—The drift on the property of the Golden Eagle Mining Co., on Spring gulch, is in now

about 400 ft., and has encountered galena that gave assay returns of \$48 per ton.

NEVADA.

ESMERALDA COUNTY.

It is announced that George W. Nixon had sold to George Wingfield his entire holdings in the Goldfield Consolidated Mines Co. Nixon was president of the company and owned 250,000 shares. The stock was taken over at \$8 per share.—The Walker Lake Gold Mining & Milling Co. is operating its property about 13 miles from Schurz. An adit 325 ft. long has been run with the intention of blocking out ore to supply a 10-stamp mill. The high-grade ore found up to the present is not in sufficient quantity to justify shipping. Altogether 1800 ft. of development work have been done. E. S. Davis is president of the company.

The Blue Dick vein at Lida belongs to Nick Parish and others. From it they have obtained rich gold, silver, and lead ore, but lack of capital to make the best of it.—The Storm Cloud M. Co. is an extension of the Blue Dick, and has an adit 550 ft. long, from which cross-cuts are now being made.—About 3 miles west of Lida the Indian Spring Copper Co. is installing a steam hoist and pumps, and have let contracts for the supply of fuel.—L. E. Campbell is working and shipping turquoise ore from the claims of the Washington-Nevada Mining Company.

NYE COUNTY.

(Special Correspondence).—The Tonopah Mining Co., at a meeting of the directors on March 25, declared the regular quarterly dividend of 25 cents per share, and an extra dividend of 10 cents payable on April 21. This makes a total to date of \$4,500,000 paid in dividends. The Mizpah shaft is now down 1296 ft., and the flow of water has increased to between 60,000 and 70,000 gal. per day. The mill report for the week shows that 3075 tons of ore were crushed.—Dennis Searles, secretary of the West End Mining Co., has announced that a mill is to be built by the company in the near future, in conjunction with the Tonopah Extension. If the West End should not erect a mill at once the Extension will construct a 30-stamp mill modeled on that of the Montana, but with Brown agitators instead of Hendryx.—The State Legislature, just adjourned, passed a law with reference to the filing of reports of mining companies. The main provisions are as follows: That every mining company operating in Nevada shall twice a year file with the County Recorder a statement of these following facts: Name of each claim and total number being worked, with their location; nature of title, and date of acquiring same; value, character, etc., of all buildings, machinery, etc., on each patented and unpatented claim; total number of days labor employed in development of each claim during the six months preceding report; total number of shares authorized by law, and par value of each; shares set aside for treasury stock, and amount realized from sale of such; number of shares of treasury stock held unsold; salaries paid during past six months preceding report. Each June and November a copy of this report shall be mailed to every stockholder of record. The bill was introduced by Senator Kendall of Nye county, and is now a law.

Tonopah, March 29.

WHITE PINE COUNTY.

The Nevada Consolidated shipped during January 1,451,000 lb. of copper; in February 1,035,000, and from March 1 to 20 inclusive, 1,086,000, or at the rate of 1,680,000 lb. per month.—Three reverberatory furnaces are in full blast at the plant of the Steptoe Valley Smelting & Mining Co. The third furnace which was blown in the first of the month, is doing good work, and furnace No. 2, which was shut down for repairs, is again in service after being out of commission only a week. Nine MacDougall roasters are now in use, but construction in progress will bring the total up to 16. The superintendent for the Minneapolis Steel & Machinery Co., has finished his contract for the steel work on the fourth unit of the concentrator. Work of placing the machinery for this unit will be commenced at once.—The general manager of the Giroux Co. has

one Keystone drill at work near the Bunker Hill shaft. Two more drills which were damaged by the fire some months ago at the Giroux smelter are being repaired and two new machines have been ordered.

No satisfactory location has as yet been found for the new shaft, to be called the Giroux, and sunk near the Alpha. It will be 5-compartment, and 18 by 10 ft. inside dimensions. A double-decked cage will handle 35 men at a single trip or will take a mine-car loaded with 9-ft. timbers without shifting the load. Two skip-ways, 4½ by 5 ft., will handle five-ton skips, working in balance. The remainder of the shaft will be used for ladder and pipe-ways.

UTAH.

BOXELDER COUNTY.

The New Eldorado Mining Co., operating in the old Ashbrook district, is advancing to development work to enable shipments to be made this summer. The president, Thomas Sherry, asserts that some of the ore runs 23% lead, 14 oz. silver, and \$1.80 in gold.

JUAB COUNTY.

Benjamin H. Bullock has found some shipping grade of copper sulphide ore in the 210-ft. level of his mine. The

has been operating to a depth of 2000 ft. for several years, and one of the largest orebodies in the mine is now being worked at that level.—The Yankee Consolidated Mining Co., in Tintic district, ships an average of four cars of ore per month, and there are five sets of lessees each shipping a carload a month from the same mine. This is a lead-silver ore, sampling from 15 to 40% lead, and 10 to 30 oz. silver per ton, with a small amount of gold. It contains also a good percentage of iron and manganese. The main purpose of the company now is thorough development, 4200 ft. of which was accomplished last year. Lewis Merriman is superintendent. The Yankee ore is shipped to the Salida smelter.

SALT LAKE COUNTY.

The annual report of the Utah Consolidated Copper Co. will be issued in a few days. Two dollars were paid in dividends in 1908, as against \$7 in 1907, and it is expected that the surplus will not be as large. The company has a contract with the American Smelting & Refining Co. for the smelting of ore, which has about a year more to run. After the contract expires the company will send its product to the new smelter in Pine canyon, which is being built by the Cole-Ryan group. E. P. Mathewson is reported to have said that the smelter will assuredly be ready for work next January, and that the saving in charges thereby effected will be equal to about \$1 per share of the stock. On the property of the Utah Consolidated are large deposits of lead ore, which so far have never been worked.

SUMMIT COUNTY.

(Special Correspondence).—The Daly-Judge crude ore shipments amount to 200 tons per month, sampling close to 21.9% lead, 16 oz. silver, \$1 gold, 11% zinc, 19% iron, and 12.8% silica. The mill is concentrating 140 to 150 tons per day, reducing 51½ tons to 1, making a concentrate that runs 32% lead, 14.7 oz. silver, 10.9% zinc, 19.7% iron, and 2% silica. Besides this, two middling products are made: one running 27% iron, 10 to 14% lead, 2 to 3% silica; the other carrying 30 to 35% zinc, 4% lead, and 14% iron. The iron middling is sold to the smelters and the zinc middling to the Grasselli Chemical Co., operating dry concentrators in the district. All the Daly-Judge ore, both milling and shipping, is brought from the mine through the tunnel which connects with the main shaft at the 1200-ft. level. The shaft reaches a depth of 1600 ft. and there are important workings as low as 1500 ft., which is 900 ft. higher than the Ontario drain tunnel that effects the complete drainage of these properties. At present a greater tonnage of ore is being taken from below the tunnel level than above it, but most of the exploratory work in progress is above that level. E. W. Durfee, general superintendent, states that the mine and mill force is 140 men. J. T. Kessel is in charge of the mill.—The Silver King Coalition Mines Co., whose operations are superintended by M. J. Daly, is shipping 100 tons of crude ore, and milling 150 per day. The average mining costs at this property for 8 months ending December 31, 1908, was \$5.64 per ton, the milling costs for the same period averaging \$1.068 per ton of ore treated. There are two classes of ore brought to the mill, a sulphide and a carbonate. In the sulphide the greater value is in the lead content, the silver being secondary, the carbonate has a preponderance of silver, but a fair percentage of lead. The average concentrate samples 45% lead and 45 oz. silver per ton. The sulphide concentrate carries 10% iron, 3 to 4% silica, and a low percentage of zinc—not high enough for the smeltermen to charge a penalty. The mill has a capacity of 450 tons per 24 hr., but is now running only one 10-hr. shift.

Park City, March 27.

TOOULE COUNTY.

The Western Utah Copper Co., operating at Clifton, in the Deep Creek region, is estimated to have 100,000 tons of ore blocked out that will assay 4.9% copper, 3.8 oz. silver, and \$1 in gold. It contains about 28% iron and 23% silica. The vein is said to be a contact between lime and porphyry, has a dip of 45°, and is 80 ft. wide at one place. It is opened by adit which give a depth of 150 ft. between the

Utah.

new vein is 2 ft. thick, and two others have been worked on the same level.—W. M. Owen, superintendent of the Eagle and Blue Belle has received instructions to advance the 1400-ft. level into the King William property. It will require about 280 ft. of work, when a raise will be made from the 1900-ft. level of the King William to the 1400-ft. level.—The Grand Eastern Mining Co. has been incorporated with a capital of \$100,000 to work eight claims in the southern part of the Tintic district. The officers of the new company are E. R. Higgenson, president, A. F. Baxter, C. E. Berry, W. E. Sainsbury, and John A. Allen.—Four furnaces are now in operation at the Tintic smelter, a copper furnaces having been blown in last week. It is believed that the starting of this copper furnace will mean a resumption of work at both the Grand Central and Victoria mines, both of which have contracts with the Tintic smelter.—The shaft at the Centennial Eureka mine is now down to a depth of 2225 ft. and a station will be cut at this point. R. A. Brown and C. E. Allen are considering putting in an electric pump of 1000 gal. per minute at this level, and then continue sinking to 2500 ft. By pumping the water to the surface through the Bullion Beck shaft about 425 ft. of lift can be dispensed with. The Centennial Eureka Co.

highest workings and the lowest adit. A winze has been sunk 275 ft. below the bottom level. The camp is in the Ibapah range, 46 miles south of Wendover station on the Western Pacific railroad. Duncan McVichie, H. H. Greene, and associates are the interested parties, with J. E. Bergh as engineer in charge.

WASHINGTON.

FERRY COUNTY.

The New Republic Co. reports having shipped five carloads of ore, and three more are ready, of which one carload will assay about \$17, another \$43, and the third about \$60 per ton. The company has contracted to deliver not more than 1500 tons of ore per month to the Tacoma smelter, for which returns will be made on a sliding scale. For all ore with 3 oz. gold or better, the entire gold content will be allowed. The low-grade ore will be used for converter linings. The last carload shipped to the Granby smelter brought returns of \$50 per ton, of which the silver was 3 oz. to 2½ of gold.—The lessees of the Surprise claim, on the Pearl Consolidated group, are shipping ore at the rate of a carload per week.—Neil Cochrane, formerly superintendent of the Mountain Lion mine and now managing the Jumper mine in California, will become identified with the camp in June.

OKANOGAN COUNTY.

An electro-chlorination process is talked of for the sulph-antimonate ore of the Ruby mine, at the base of Mt. Chopaca. Monroe Harman, the manager, after having witnessed a 30-hr. test run, has pronounced the saving to be satisfactory, and, with the exception of a few slight defects which may be easily remedied, he thinks the process is suited to the Ruby ore.—An 18-hp. gasoline engine is being installed at the Forty-Ninth Parallel mine, near Oroville. A hoist will also be installed, and the shaft sunk to 100 ft.—Placer mining on the Golden Sands claims, on the Similkameen river, three miles above Oroville, is to be resumed by Milwaukee people. An examination of the property has indicated ground worth over \$4 per cubic yard.—Funds are being raised in the East for extensive improvement of the water-power of the Similkameen Falls Power & Development Company.

STEVENS COUNTY.

C. J. Johnson, secretary of the Oriole Mining & Milling Co., operating in the Metaline district, announces that tunneling has proved that the No. 1 vein is a contact deposit. There are now 3½ ft. of solid shipping ore carrying silver, lead, and gold worth from \$35 to \$100 per ton. Another vein is 8 ft. wide on the surface, and will be tapped at a depth of 300 ft. The company has a contract to transport its ore from the mine to Newport for \$5 per ton.—The Liberty Copper Mining Co., operating six miles west of Chewelah, has shipped its first carload of ore to the Northport smelter. The ore is from a blind lode encountered in the main adit, hand samples from which assay between \$40 and \$50. Two shifts are employed at the mine.—Merryland Mining & Development Co. has been organized in Spokane with a capital of \$1,500,000 to develop a group of five claims in the Metaline district. W. C. Halliday, who located the property, is president; C. W. Benedict, O. H. Benedict, William Tyler, and R. E. Leslie are the other officers. Assays from the vein indicate ore payable in silver and lead.—The Gold Dyke Mining & Milling Co. has been organized, with \$1,000,000 capital, to operate the Lightning and Condor claims, in the Orient district. The incorporators are T. J. Demorest, of Spokane, Fred Buhrig, of Orient, A. M. Glick and A. B. Willard, of Tekoa.—A large shipment of supplies has been sent to the Zodiac mine, on Sophia Mtn., near Northport, for extensive development work.—The adit on the North Star mine is in 375 ft., and ore has been found which assays \$20 in gold and over per ton.—The management of the Easter Sunday mine expects to have its mill completed and running by April 15.—Galena of fine quality has been uncovered in the shaft on the Sunday Morning mine, near Rock

CANADA.

BRITISH COLUMBIA.

The British Columbia Copper Co. has shut down its Mother Lode and Oro Denora mines, and the smelters at Greenwood. J. E. McAllister, the general manager, says they will remain shut down indefinitely until the market conditions improve. It will throw about 400 men out of work.—The Nuba and Early Bird mining companies will jointly install a 20-stamp mill on Moresby Island early in April. The order for the plant has been placed in Germany. The Nuba company owns 54 claims near Gold Harbor. Twenty men have been engaged at development work since last fall. Both properties are traversed by the same vein, which varies in width from 2½ to 8 feet.

MEXICO.

FEDERAL DISTRICT.

The manager of the Esperanza Mining Co., at El Oro, reports a new discovery of gold-bearing veins of high value. Cross-cut No. 21, on the ninth level, north section, passed through two sulphide veins 3½ ft., and 5 ft. 10 in. wide, assaying \$17.50 and \$21 gold per ton, respectively. Cross-cut No. 24 west is also in good ore, but particulars are not known.

OAXACA.

(Special Correspondence).—L. V. Ulrey, of the Indiana-Oaxaca Mining Co., is visiting Mexico, to make the final payment on the company's property near Teojomulco. The mines are in charge of Guy L. Caulfield, who has made a satisfactory showing for the property. The last shipment of ore to the smelter showed an average of \$194 per ton. The company expects to install a mill shortly.—The Natividad mine, famous as the richest mine in this State, is in the throes of internal faction between the directors and stockholders. It is generally understood that the opponents to the present president have secured 56 majority for the final meeting to be held on April 3, when it is very probable that a Mexico City man will be elected in his place. The company is controlled entirely by Mexican capital.—The Ocotes mine, the property of the Teziutlan Copper Mining & Smelting Co., is arranging to install diamond-drills for prospecting the property in depth. The company has been securing water concessions for some months past.—The management of the Santa Sophia mine in the Parian district expects to begin the erection of a mill within six months from date. The company is controlled by Boston capital.—C. W. Hunt, of Boston, has been in the Oaxaca district for some weeks investigating the mica production of the State. He has discovered sufficient good mica to warrant shipping the mica in the rough to the States and has made the first consignment.—The onyx of the Etla quarries is now controlled by Ingel Carpenter, of Mexico City. Recent beds of fine green onyx have been uncovered, which meets a popular demand in the New York market. The name of onyx, however, is a misnomer, as the stone in question is really nothing more than marble and is being so billed for the customs duties into the States.

SONORA.

The annual report of the Greene Consolidated Copper Co. covers 6 months of actual operation under the management of L. D. Ricketts, and shows a net profit of \$1,606,300. The cost of mining for the total tonnage was \$2.13 per wet ton. For fifteen months, ending October 1, 1907, it was \$3.28. The cost of concentrating domestic ore, 3.12 tons into 1, was 94c. per ton, obtaining a recovery of 2.65% copper, 0.92 oz. silver, and 0.0075 oz. gold. A dam is being built to store 2,000,000 tons of tailing, hitherto thrown away.

Col. W. C. Greene is credited with the announcement that a new corporation is being organized to take over all his properties in Mexico. The new syndicate will have \$40,000,000 capital and is headed by F. S. Pearson of New York. Other prominent men interested in the corporation are José Limantour, Sir William Van Horn, and E. N. Brown.

Special Correspondence.

MEXICO.

Pachuca.—La Blanca Bonded. — Big Dividends. — Batopilas Production.—Discoveries near Ocampo.

Special interest has again been drawn to Pachuca, the famous old camp in the State of Hidalgo, by the recent report that a 90-day option has been taken and that examinations are being made by John B. Farish on the La Blanca property. The price is placed at \$8,000,000. The excellent results obtained by A. F. Holden and associates (or the United States Mining, Smelting & Refining Co.) from the Real del Monte properties has caused many others to look with a jealous eye in that direction, and La Blanca has been mentioned several times as being under option and examination since the sale of the Real del Monte. It is to be hoped that a strong foreign company may get hold of La Blanca, for it is one of Pachuca's largest properties, and it is claimed that ore to the value of \$30,000,000 has been blocked out. However true this may be, it is certain that, handled on a large scale, it would give excellent returns on a capitalization as high as the Real del Monte, which has paid dividends exceeding \$1,500,000 in the last 12 months. In addition to the above-mentioned properties, all the others at Pachuca seem to be in excellent condition; the Sorpresa, Soledad, and San Rafael-Trompillo, may be considered in bonanza; they are paying excellent dividends; the San Rafael is approaching completion on two new stamp and cyanide mills, the San Rafael and La Union, the former in fact being partly in commission. When wholly completed they will treat 600 tons between them—350 tons per day of mine-filling, dump and low-grade ore at the San Rafael, and 250 tons per day of the higher grade ore at the La Union. The Santa Gertrudis, which has been a dividend-payer for 35 years, having had ore at 90 ft. from the surface, is stated to be now in bonanza on the 17th level at a depth of 500 metres, where they have driven over 300 metres on a 12-m. vein which yields shipping quantities up to 4 kg. and over of silver per ton. The San Antonio, one of Pachuca's new mines, has opened up, at a depth of 100 metres, a 5-m. vein of 1-kg. ore, but it is the intention of the company to sink to a depth of 200 metres before doing systematic development. The Sonora & Urés Co. is another new company which is sinking near La Blanca and the Santa Gertrudis; and the Pachuca M. Co., Ltd., is a new \$1,000,000 concern which has been formed to operate on some 50 pertenencias near the Santa Gertrudis.

Chihuahua continues to be the centre of some of the most important old and new work in the Republic. The Batopilas mines, in the western part of the State, which since 1880 have produced over \$22,000,000, are again in excellent condition, the production in both December and January reaching over \$200,000, and for February and March, \$300,000. The entire product is shipped out as bullion from the stamp and amalgamation mill and goes to Philadelphia, but a cyanide plant is now to be added, and it is believed that much of the ore that cannot now be profitably treated will give a nice profit from cyanidation. The Rio de Plata and the Republica, also in the great mineralized region of western Chihuahua, are keeping up production of high-grade concentrate and getting settlements from the smelters of something over \$40,000 per month. Both properties have been greatly hampered in the running of the mills and in the installation of the cyanide plants because of the unusual lack of water, which has been a serious question this year. Up to the present there have been none of the late winter and early spring rains that are so necessary in this country, where there are no heavy snows to melt and fill the creeks and streams. Another comparatively new field is that

around Uruáchic, to the south of Ocampo and Pinos Altos, where a good grade of lead and copper ore running well in gold and silver is being developed. Small but rich shipments are being made by T. A. Ripperdan and E. Rascon. The former has organized the American-San Timoteo Mining & Smelting Co., and will endeavor to put a small smelter on the property, as there is plenty of ore besides his own which could be profitably handled by a local smelter, but could not stand the \$50 transportation charge from the mine to the railroad, with other freight and smelting charges added to that. The most noteworthy and remarkable work of the past year is that of J. S. and Charles Qualey at Yoquív, not far distant from Uruáchic, on the San Francisco mine, held under option at a low figure from Enrique C. Creel, governor of Chihuahua. With only a windlass they have opened a strong quartz vein giving shipping quantities as high as 20 oz. gold and 1500 oz. silver. In addition to several hundred tons of lower-grade ore on the dump, they have shipped five car-loads, giving a smelter return of \$25,000 on the first car-load and twice that on the fifth car of 60,000 lb., or \$1 per pound. The Qualeys are now installing hoisting machinery, and promise the people of Chihuahua shipments of enormous value.

CHICAGO.

Dering Receivership.—Steel Corporation's Fuel Policy. — Coal-Land Value.—Fuel Conference.—Mine Accidents. — State Geological Surveys.—Wisconsin Lead and Zinc.

The Dering receivership continues to be the leading topic of conversation among Chicago coal men. Because of the

The Patio Process at Pachuca.

light shed on coal matters in general, and on the policy of the U. S. Steel Corporation in particular, it may be of interest elsewhere. Nominally the Dering Coal Co. was put into the hands of a receiver, W. C. Niblack of the Chicago Title & Trust Co., because of the failure of certain subsidiary companies of the U. S. Steel Corporation to pay a certain \$215,000 claimed in disputed settlement, and needed by the coal company for meeting interest charges on April 1. It seems that the Dering Coal Co., having taken a 50-year contract to supply the Steel Corporation with steam-coal, finds the price too low, and the contest is between H. C. Frick demanding his pound of flesh, and R. R. Hammond attempting to save something for himself and fellow stockholders. The mines concerned are near Danville, Illinois. Some years ago Mike Kelley, a vigorous and picturesque character, developed this field, and obtained large contracts for supplying 1,000,000 tons per year, to the Illinois Steel Co. It is the field nearest to Chicago of any having thick and cheaply mined coal. The mining rate there has been a disturbing factor, and is now the basal rate in labor settlements throughout Indiana and Illinois. Kelley died wealthy, and left his property to children who have squandered the proceeds of bond sales in recent years. The stock passed

into the hands of the McKinley traction interests, and the contracts were undisturbed. Adverse conditions, however, took out most of the profit, and when a few years later the Dering, a newly organized competing company, offered a price of 10c. per ton lower, no great regret was expressed. Soon after, in order to fill the contract, the Dering interests took over the Kelley Coal Co. This was later put through a receivership, and has just been bought by the Hammond Coal Co., an affiliated organization which controls the newer and better properties of the Dering company. Things have gone from bad to worse in attempts to fill the contract with the Steel Corporation. The coal is delivered to the latter at the mines, the steel company running its own trains over the Chicago & Eastern Illinois railroad to South Chicago. This season it is stated that coal has been sold as low as 78c. per ton, and even with prospective demands for 10,000 tons per month, this meant ruin. For some weeks the Steel Corporation and the coal company have been unable to agree on dockage charges, and the former has been buying wherever coal could be found on 30-day contracts. Since, however, this involves paying normal railway rates in place of 15c. per ton 'running rights', it is evidently a temporary expedient. Either the Steel Corporation must give Mr. Hammond and his associates a new contract at more remunerative rates, or it must bid against him and purchase mines of its own. Some interesting jockeying is evidently in prospect.

Incidentally, an interesting side-light on coal-land values is cast by the statement of the petitioners that the coal company has property reasonably worth \$6,000,000 represented by 200,000,000 tons of marketable coal in the ground. The low value of the coal, well situated for mining and marketing, and of good quality, is a striking commentary on the large amount available in this field, and the present unsatisfactory conditions of the coal market.

Evidence of the latter is also seen in the failure of the proposed combination of mines tributary to East St. Louis. Last week mine-run was offered there at 65c. per ton f.o.b. at the mine. Much has been sold this winter at 80c. At the latter price operating expenses are just about cleared, leaving nothing for interest charges or profits. This seems to be due to the presence of short industrial railways owned by certain of the mining companies. So long as the market can be controlled with a single locomotive, it is not necessary to consider mine-profits. Railway rates have been frozen stiff by recent legislative enactments against rate-cutting and rebates, and there is a fine profit in a railway haul at 42c., when formerly the actual rates paid, taking into account rebates, fell as low as 10c. without putting any road into the hands of a receiver. Just now the pay-rolls at many mines are met on borrowed money, and many banks are carrying oft-renewed notes of coal companies. Unless conditions change for the better, a number of additional companies will undoubtedly go into the hands of receivers.

All this bears on the anthracite strike-question. Nearly everyone concedes that there is insufficient ground for a successful strike, and that the time is most unfortunate for the miners. Few think a bona fide strike will occur. A strike there means temporary prosperity to both operators and miners in the fields of the Middle West, where so many men are nearly desperate.

A Fuel Conference was held at the State University, Urbana, Illinois, last week. The occasion was the opening of the new mine-rescue station, which is a co-operative enterprise, supported by the University, and the State and U. S. Geological Surveys. The conference was well attended by representatives of the miners, the operators, the Survey-officials, and State Mine Inspectors from Indiana, Illinois, and Iowa. Mine-accidents, smoke-prevention, and fuel economy were discussed in numerous papers, and resolutions were passed calling for future conferences, and for a mining department at the University. The situation in the latter particular is anomalous. The trustees of the University are asking this year for \$1,000,000 for experimental work in agriculture, but refused the modest request of Dean Goss for \$25,000 for mining work. With an annual

mineral-output of \$150,000,000 it would seem that the mining interests of Illinois were entitled to more consideration.

Mine-accidents continue with alarming frequency. The last was at the Sunnyside mine, in Evansville, Indiana, where on March 20 five men were killed by an explosion caused by a 'windy shot'. Since 26 men escaped, there is a general feeling of relief. R. Y. Williams, of the Urbana Mine-Rescue Station, went promptly to the scene of trouble.

The Geological Surveys are busy with plans for the summer. It is understood that the U. S. Geological Survey will need a number of additional men. Frank W. DeWolf, Assistant State Geologist, has been made Acting Director of the Illinois Survey. Mr. DeWolf has had charge of the coal-work for both the State and the Federal Surveys in their territory, and is a competent man, whose selection for the post will be generally approved. In Indiana the Legislature not only did not follow the recommendation of Governor Marshall that the office of State Geologist be abolished, but actually increased the appropriation. In Missouri, Governor Hadley sent a special message to the Assembly, calling attention to the good work of the State Survey, asking for a larger appropriation, and urging that the State Mine Inspectors be appointed by the State Geologist. There is no question that mine inspection in Missouri has been lax. How far the proposed change would be helpful is open to question.

Later developments in the Wisconsin lead and zinc mines seem to show that the peculiar form of orebody found there, known as 'flats and pitches', extends below the 'glass-rock'. It has been known for some time that important orebodies were found at that lower horizon, but where first opened they were irregular and hard to follow. The new development will make mining more certain.

SALT LAKE, UTAH.

Conference of Lead Producers — Memorial to Congress. — Mascot Tunnel.—Ohio Copper Co.—New Concentrator.

A conference of lead ore producers, called together by J. F. Callbreath, secretary of the American Mining Congress, was held at Salt Lake City on March 22 and 23. It was attended by over twenty mine operators from Utah, Idaho, and Colorado, who organized the Western Lead-Ore Producers' Association. The object is to protest against the proposed reduction by Congress of the import duties on lead in ores, and upon metallic lead. Harry L. Day presided and Geo. W. Riter acted as secretary. Brief speeches were made by W. F. James, of Salt Lake; C. E. Loose, of Provo; I. E. Rockwell, of Hailey, Idaho; C. E. Allen, Geo. W. E. Dorsey, H. S. Joseph, and Geo. W. Riter, of Salt Lake; M. A. Folsom, of Idaho; and J. F. Callbreath, of Denver. A committee on resolutions, comprising J. F. Callbreath, W. Clayton Miller, M. A. Folsom, J. W. Knight, and Jackson McCrystal, drew up a memorial for presentation to Congress, which was adopted by the Association, emphasizing the importance to the lead mining industry of a protective tariff upon lead and lead-ores, and calling on the party in power to redeem its pledge, made before the last national election, to maintain a tariff on all products sufficient to balance the difference between the cost of production here and abroad. The future work of the Association was left to the discretion of an executive committee, consisting of H. L. Day, W. D. Hoover, J. F. Callbreath, Geo. W. Riter, and Ernest Bamberger. It was decided that the lead-mine operators of the several States should send a representative to Washington to work in the interest of retaining the present tariff rates, namely 2½c. per lb. on pig lead and 1½c. on lead in ores. Among the operators in attendance, in addition to those mentioned, were Jas. F. McCarthy, of Wallace, Idaho; Samuel Newhouse, B. N. Lehman, M. C. Morris, Grant Snyder, W. B. Fisher, Matt. Dougherty, John McCrystal, and A. W. Scott, of Utah.

The mineralized zone of the Ohio Copper Co., in Bingham district, has an easterly strike, and a dip to the north of about 45°. It is a zone of mineralized quartzite more than

500 ft. wide, adjoining porphyry on the north. This belt of quartzite contains two parallel veins, in each of which the ore is high-grade, and participates in the same strike and dip as the general zone. These are known as the What Cheer and All's Well veins; the former is on the south border of the belt, near the contact of the quartzite with the porphyry; the latter is on the northern border, and appears to have a hanging wall of porphyry. The two veins are more than 500 ft. apart, the material between them being solid quartzite, carrying sulphide of copper, said to assay 1.6 to 1.8%. In the earlier period of the mine-development a cross-cut adit was driven 600 ft. from Bingham canyon, intersecting the What Cheer at 100 ft. from the portal, and opening the All's Well 500 ft. farther on. From this level drifts were run on both veins, raises were made on the ore, stopes opened, and a considerable tonnage of high-grade ore was shipped, much of it being cuprite. While ore from these veins is rich, the paystreak is narrow, ranging in width from 6 in. to 3 ft. Later a 400-ft. winze was sunk on the All's Well from the main cross-cut level, and from this winze extensive development was done on the 400 and 500-ft. levels, the main cross-cut from the surface being considered the 100-ft. level. This winze is now abandoned, as other provisions have been made for reaching the deeper levels. Recent development consists of a 1400-ft. incline-shaft which starts in the foot-wall of the What Cheer vein and terminates in the quartzite and porphyry between the two veins. This shaft has an inclination of 50°, is two-compartment, with track for a skip in each. The shaft is timbered to a depth of 1100 ft., and the work of timbering the last 300 ft. is now in progress, the tracks for the skips being extended as fast as timbering proceeds. The incline connects with the Mascot tunnel, and the lowest 300 ft., which was a raise from the tunnel-level, was recently completed. The workings on the 100, 400, and 500-ft. levels have been connected with the 1400-ft. incline. On the 100-ft. level is a mineralized area 500 ft. square, which has been blocked out. It is stated that the development on the 400 and 500-ft. levels is almost as extensive. Ore from the lowest workings, where the incline connects with the Mascot tunnel, seems much the same as that where the development is greatest in the upper workings. The Mascot tunnel starts on the Salt Lake valley slope of the range, taking a westerly course for over 14,000 ft., cutting into the foot-wall of the All's Well vein and running parallel with it through the ground of the Ohio Copper Co. The last 1200 ft. of this tunnel was driven within the last year, and the part which was originally driven as far as the Dalton and Lark areas has been enlarged so that the entire bore now has a section 7 by 7 ft., except that there are three 500-ft. switches where it is broadened for double tracks. The grade is 0.58% for the first 9000 ft., and 0.42% for the remainder of the distance. The track is laid with 40-lb. rails, a box-channel or sluice below the ties serving to drain a large volume of water. The raise that was made from the tunnel-level to meet the incline-shaft was surveyed by Frank B. Goodman, one of the engineers of the Ohio Copper Co. The survey was checked by J. E. Bergh, and the exactness with which their calculations agreed was evidence of the skill of both. The plan is to develop the zone on the level of the Mascot tunnel in a manner similar to that on the upper levels, and to make three raises from the Mascot level to the 100-ft. level, and take all ore out through the tunnel in 4-ton cars. This contemplates a system of levels and raises from the 100 to the 1400-ft. level, representing a vertical depth of 1000 ft. At the mouth of the Mascot tunnel is a smooth open country, where is situated the air-compressors, the concentrating mill, administrative offices, and the town of Lark. It should be stated that the Mascot tunnel is the property of the Bingham Construction Co., the stock in which is owned by F. A. Heinze and associates, Mr. Heinze being a heavy shareholder in the Ohio Copper Co. The mill for concentrating the ore of the Ohio Copper Co. is still unfinished. The steel building, 350 ft. square, is covered with corrugated iron and lined with asbestos. The necessary concrete blocks for the machinery are now complete. The equipment

has been bought, and much of it has been delivered, but not installed. The plant will have crushers, rolls, Chilean mills, jigs, tables, and vanners. Its capacity is figured at 2250 tons of ore per day. It is said the work of installing the machinery will proceed at once, and will be ready for operation July 1. The mill has been largely patterned after that of the Boston Con., at Garfield, Utah. The big mills of the Utah Copper Co. and Boston Con. operate almost exclusively on copper ores having a porphyry gangue, but the Ohio Copper Co.'s mill will treat almost wholly a copper-bearing quartzite, which will not slime so readily. On the operating staff of the Ohio Copper Co. are Colin McIntosh, general manager; Felix McDonald, mine superintendent, and Frank Jones, mill superintendent. James McFarland is president of the company.

DENVER, COLORADO.

Development in the Sulphide Belt. — New Companies. — Gunnison Tunnel. — Denver Coal-Field. — Altman Leasing Contract.

Seldom has Denver been so completely cut off from other centres as by the blizzard of March 25. Railroad traffic was paralyzed, and telephone and telegraph lines were down. The whole northern part of the State was affected. The prevailing warm weather, however, makes the delay in development work only temporary. Almost every proposition

Western Colorado.

in the sulphide belt that has any merit has resumed development, and an active season is assured. The initial trial of the Sigafos tunnel-machine took place at the Georgetown tunnel, on Columbia mountain, March 24. It was the first trial under working conditions. Heretofore the company had been unable to secure water to clear away the muck. The trial lasted 15 min., and the machine advanced steadily at the rate of 1 in. per minute.

Two new companies have been formed which should have a beneficial effect on mining and irrigation. The Great West Consolidated Mines Co. has been incorporated, with Ross MacDonald as president. This company has secured control of the Little Pittsburg group of claims, in Saguache county; the United States Navy gold and copper claims, in Chaffee county; the IXL and Pewabic mines, in Gilpin county; and the Nebraska mines, near Silverton. The other new corporation is a power and irrigation company, which has filed plans for the construction of three reservoirs on the Cache la Poudre river. The pipe-lines and ditches from these reservoirs will supply water to 149,800 acres in Larimer, Logan, Weld, Yuma, Adams, and Boulder counties. Power-stations will also furnish electric power to mines and tramways in competition with the Northern and Central Colorado Power companies. The Penn-Wyoming Copper Co., which recently got into financial difficulty, has

been absorbed by the United States Smelters Railway & Copper Co. The holdings of this company now consist of the Ferris-Haggerty mine, Saratoga & Encampment railroad, Southern Wyoming tramway, Doane-Rambler mine, and the Encampment smelter. The consolidation of these concerns under one management should prove of benefit.

Prospectors are busy in the mountains west of Montrose, and land speculation is booming in the Uncompahgre valley on account of the completion of the Gunnison tunnel, which is to be dedicated by President Taft on August 16. The tunnel will furnish water to 150,000 acres, and before the water is let into the river again it will generate 20,000 horse-power.

During the summer of 1908, members of the U. S. Geological Survey made a detailed study of the coal-field on the eastern slope of the mountains in Colorado. The limits of the Denver coal-field were found to be from near the Wyoming line south to include the Colorado Springs coal-field, and to extend east from the foot of the mountains, for about thirty-three miles. Although no outcrops of coal occur between Denver and Colorado Springs, there is reason to believe that good coal will be found between these two cities, under considerable cover. The work on the Colorado Springs field was done by Marcus I. Goldman, under the general supervision of G. C. Martin, who had charge of the investigation as a whole. A bulletin of the survey will soon appear covering this subject.

Leases in general admit of much variety in point of terms and conditions specified, but it is uncommon to find one which reserves the upper part of an extensive claim-group and gives to lessees the right to mine below their lowest level. Such an undertaking has been made the basis of a five-year lease recently given to the Altman Leasing Co. by the Free Coinage Gold Mining Co. on their 30-acre tract, beginning from the horizon of the 550-ft. level of the Pinto shaft, downward to any depth to which the lessees can carry operations within the time-limit. This is conditioned upon sinking the main shaft several hundred feet deeper. It is a good example and a practical expression of confidence in development of ground that is central to some of the richest parts of the Cripple Creek district, lying, as it does, between the Isabella mine and Vindicator groups on Bull Hill, about the town of Altman.

The Free Coinage Gold Mining Co.'s property includes the vein-systems of the Pinto-Pharmacist, Wilson, Pinto-Bison, and Pueblo mines, and is among the successful companies of the early days of Cripple Creek; it is now being actively worked at several levels, all under the leasing system. Since 1894 this group has produced from $1\frac{1}{4}$ to 2 millions of dollars, from workings that are superficial as compared with those of its neighbors. Among the latter are the Isabella and Findley, which reach depths of 1100 and 1400 ft. below the collars of their respective shafts.

The Altman Leasing Co. is installing a powerful Vulcan geared hoist, of capacity to reach to a depth of 1500 ft., which will take the burden from the present equipment before it reaches its limit. Combining the features of large acreage with its location in the midst of the most productive mines of a rich section, there is probably not a similar mineral tract in the district that can be leased in a compact group. In addition to the main 'deeps' lease, this leasing company has two blocks above the 550-ft. level, in one of which high-grade ore has been discovered through prospecting upon the Black dike of the Bison claim, which corresponds with the Isabella dike of the Government report upon the mines of this portion of Bull Hill. Air for machine-drills is taken from the Union Leasing Co. from the plant at Deadwood. At first a small force is being employed in shaft-sinking and in prospecting. Extensive drifts and cross-cuts make available to stoping much promising ground, without costly outlay in dead-work. The management is enthusiastic over the prospect of early shipments. The new company is organized under the laws of Colorado, with a capital stock of \$100,000. The principal office will be maintained in Cripple Creek. Geo. R. Woodin, of Boston, is the moving spirit of the enterprise.

NEW YORK.

Zinc and the Tariff.—Senate Tariff Bill.—Exchanges and Gambling.—Concheno Mine, Mexico.—Cobalt Stocks.—Mill at Pioche.

Zinc smelters are greatly alarmed by the Payne tariff bill. The largest smelters mine and import zinc ores as well. They are compelled to do this through the necessity of keeping the smelting plants in regular operation. Owing to the all-round changes it is proposed to make in the tariff zinc smelters will feel the effects in all their operations, and in some cases they may be compelled to discontinue smelting, which, they claim, is not the most profitable part of the zinc industry.

The Payne bill proposes to change the duties on spelter from $1\frac{1}{2}$ to 1c. per pound; of sheet-zinc from 2 to $1\frac{1}{4}$ c. per pound; and to place a duty of 1c. per pound on zinc in ores. The average price of spelter in Joplin in the past 10 years amounted to 5.05c. per pound. Owing to the general appreciation in prices it is not unreasonable to expect the average price, if no tariff changes be made, will in the immediate future range near 5.25c. per pound. With an increase in ore-costs the smelters' margin of profit is liable to be wiped out.

Smelters complain that they are menaced by a restricted consumption of spelter, competition of foreign smelters, and a shortage of a suitable domestic ore-supply. They do not ask for a prohibitive duty on spelter, but for a reasonable one. A prominent smelter expressed the opinion that a 20% *ad valorem* duty would be considered reasonable. No objection would be made to a sliding *ad valorem* duty, increasing and diminishing in accordance with the price of spelter in New York or Joplin. When spelter is 5c. per pound the duty would be raised to the maximum and reduced in proportion to the advance in the domestic price. The main concern of the smelters is to see the duties arranged in a sufficiently flexible manner to enable them to keep their plants in steady operation.

There should be hope inspired by the advices from Washington to the effect that the tariff bill prepared in the Senate will be the real bill, and that its provisions will be far more conservative than those in the Payne bill. It is currently affirmed that the report of the New York State Commission, which recently investigated the various exchanges, including the New York Stock Exchange, will exonerate them from blame in the matter of stock gambling. Whatever gambling in stocks is carried on is not within the precincts of the exchanges. The grand jury and the district attorneys should concern themselves with such gambling. Notwithstanding the severe way in which the chairman of the Exchange Commission expressed his opinion regarding the fixing of the prices of metals on the New York Metal Exchange, that institution continues its old practices. The prices of copper, spelter, and other metals and metal-products are fixed, as formerly, in correspondence with the fluctuations in London prices. Some of the members of the Exchange are endeavoring to form a new exchange, where some freedom of competition in price-fixing would be permitted. There hardly seems room for a new metal exchange.

Henry Ide Willey, president of the Humboldt Exploration Co., who is at present at Chihuahua, Mexico, has denied the reports regarding the taking of options upon the various properties in Mexico that belonged to the Greene Gold-Silver Co. Mr. Willey states that he is concluding arrangements to take over the Concheño and other mines formerly owned by the Greene concern, for the benefit of the stockholders of that company.

Notwithstanding that Cobalt stocks have been dull in New York during the past half-year, a number of Canadian companies operating mines at Cobalt are making arrangements to list their stocks on the New York and Boston curbs. Preparations are also being made to bring out some new Cobalt issues in New York shortly. It is believed that the improved outlook for silver in the Orient, and commercial prospects in America, warrant the belief that mining investments will again become popular within the next few months.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Resistance to the solvent action of acids may be increased by certain elements added to alloys. Acid-resisting alloys possess either a high content of lead or antimony. Silicon is added to cast-iron in order to effect the same end.

Silver retains its whiteness in spite of large admixtures of copper; in fact, it only begins to acquire a yellowish tinge when the proportions are 6 of silver and 4 of copper. The hardest alloy of these two metals contains 312.5 parts silver and 687.5 copper.

Guide vanes are advantageously fitted to the interior of hydraulic giants to prevent a scattering or rotary motion of the water after it has issued from the nozzles. They tend to discharge the water in a solid and columnar form, thereby largely increasing the effectiveness of the stream for hydraulic mining.

Smelting of black sand for iron is economically impossible in the blast furnace. Fine ores are always objectionable in blast-furnace practice, owing to the enormous loss in the dust carried off by the flue-gases. The electric furnace, however, opens a new field, the utilization of fines being feasible under the conditions there presented.

Garnet sands, found in such great quantities at Nome and other places in Alaska, do not lend themselves to commercial exploitation because of the great amount of garnet available for use as an abrasive nearer the centres of consumption, as for example in Raburn county, Georgia, and in Burke county, North Carolina, where extensive deposits are worked.

Friction in crushing ores, either wet or dry, develops enough heat to promote oxidation of susceptible substances. For example, FeO is to some extent oxidized to ferric hydrate, and sulphides of iron and copper are oxidized to sulphates. The amount of such oxidation-products is by no means negligible in the subsequent metallurgical treatment of gold and silver ores.

Saving of black sand from beaches has not proved a practical success in any part of the world. The difficulty is that the black sand is seldom free enough from iron-minerals containing other elements to be valuable as an iron ore. A few such deposits exist, and a remarkable one is reported from the east coast of the island of Martinique, in the Lesser Antilles, stretching for several miles along the beach not far from the base of the volcano of Peleé.

Polished gems generally develop high electric properties by being rubbed on cloth. This is particularly true of the topaz, and is a notable characteristic of the diamond, either in the rough or when cut. The topaz becomes electric by the application of heat;

this property of becoming pyro-electric is shared by tourmaline, the latter mineral developing polarity, attracting and repelling on opposite sides, as may be tested by the needle of a compass. Zircons, sapphires, and rubies are non-electric. Quartz may be distinguished readily in the field by rubbing two pieces together, when the peculiar odor known as 'fire-stone' smell is given off.

German cement manufacturers are tending to less severe specifications, while American specifications are all in the opposite direction. In Germany an Association of Portland Cement Manufacturers makes regulations which are generally accepted, just as the specifications of the American Society of Civil Engineers rule in this country. One may be suspected of bias, the other is interested only in safety and durability. The following requirements show the comparatively easy task of the German cement manufacturer: 3% of set-retarder permissible; for fineness, No. 76-mesh screen is used, on which 5% of the sample may remain; tensile strength, 3 sand to 1 cement, at 28 days, 224 lb. per square inch. Corresponding American requirements are 2%, 5% on 100-mesh, and 300 lb. tensile strength.

Antimony ore will not be accepted by the smelters unless it contain at least 50% of that metal. The specifications, furthermore, demand freedom from arsenic and lead. These conditions are usually difficult to meet. The economical separation of gold and silver from antimony is not simple. A process of alternate roasting and reduction of the ore, mixed with charcoal breeze, will eliminate antimony by volatilization, and in certain cases should leave a residuum containing the precious metals, which could then be treated by other means, if other base metals do not interfere. In fact, by such a process the presence of lead can be turned to advantage by the metallurgist in collecting some of the precious metals, if the lead be present in sufficient quantity. This work can be done in a reverberatory of the Bleiberg type with sloping hearth.

Graphite is so abundant that only special qualities, or favorable situation, can justify exploitation. Any deposit of magnitude, however, is worthy of careful investigation. Graphite of different degrees of purity and of different textures is needed for special uses. The classifications are too many to be explained here. The purity of the graphite flake itself is a matter quite distinct from the association of the graphite with gangue. The graphite, after concentration from the matrix, needs to be tested as to its merchantable quality. The concentration of this substance presents some peculiar difficulties, and even these vary with the deposits. In general, successful results can be obtained by crushing to the 'critical size,' that is, the coarsest size which will liberate the major part of the graphite, jigging, classifying to float off as much fine graphite as possible, re-grinding the settled material, re-jigging, and so on until the residue is too fine for jigging, when various methods of hydraulic classification and elutriation are relied upon.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Tailing-Wheel v. Pump.

The Editor:

Sir—On the lines of Mr. Peele's communication in your issue of February 13, it is interesting to note that some ten years ago we made an attempt to use an air-lift for raising tailing in the Standard mill, at Bodie, California. The operation was satisfactory as long as the whole mill was running, but if five stamps were hung up, the lower end of the uptake pipe soon became blocked. This was because the decrease in velocity in both submersion pipe and uptake allowed the heavier particles to settle and close the entrance to the uptake. Under normal conditions the downward velocity of the current in the submersion pipe was sufficient to scour the accumulation away, and the upward velocity in the uptake was calculated so as to be greater than the falling velocity of the most quickly falling particles. With decreased flow, however, both velocities fell, the nice balance was destroyed, and blocking resulted. The mill was of only 20 stamps, and it was essential that the lift should operate when only 5 heads were dropping. Accordingly, if we had diminished the diameter of both submersion and uptake pipes so as to give the proper velocity of flow for the minimum amount, the velocity would have been four times greater than necessary for the greater part of the time with 20 heads dropping. This meant greater friction and more air required. Accordingly, the device was abandoned and replaced by Frenier pumps.

Short Zinc.

The Editor:

Sir—In your issue of February 13, page 246, you refer to the ill effects of iron present in zinc used for gold-precipitation purposes. This opens an interesting subject. The phenomenon of 'short-zinc' so-called—the rapid crumbling or disintegration of zinc-shaving—has been observed under varying conditions. My own observation would point to its being due in most instances to the presence of iron, not, however, so much in the zinc itself as in the solution, and in the material of the zinc-box. I do not think the small amount of iron in the better grades of commercial zinc can be appreciably detrimental. The worst case of short-zinc I ever saw was in a plant where I was treating a deposit of old oxidized tailing, full of soluble iron salts. The solutions were reddish-brown in color. Here the consumption of zinc was alarming, while zinc supplied by the same firm was perfectly satisfactory in other cyanide plants in the same district. In the case referred to, the shavings

would become so brittle after an immersion of an hour or two in the solution, that they could be compressed in the hand into a hard compact mass of short-zinc. This was doubtless due to the galvanic action set up between the zinc and the iron. I have seen zinc crumble badly in boxes made of iron, where, at exposed points not covered by protective paint, a small line of bubbles could be seen issuing from the unprotected surface. The complex chemical reactions and galvanic phenomena of zinc-precipitation have not received as much attention from cyanide chemists as they deserve—possibly because, as a rule, in practical work precipitation offers no serious difficulties. Until this subject is more definitely understood it may spare the operator some trouble if he will remember to keep zinc and iron as far apart as possible in his precipitation boxes. In the meantime it would be interesting to know something more of the experience and researches of metallurgists in zinc-box work.

Protecting the Investor.

The Editor:

Sir—Anent the recent discussion in the Mining and Metallurgical Society concerning measures for the protection of the public, there will doubtless arise the various difficulties that hamper most reform movements. One of these that seems just now coming above the horizon is the conflict between the desire to enforce high ideals and the necessity for exercising the virtues of patience and tact in striving for their realization. "The over-valuation of mining properties by investors and the public, due to ignorance of mining conditions and a lack of appreciation of the real nature of the investment," with the serious abuses that have grown up in consequence of these conditions seem to demand not only a frank statement of all available facts and estimates in every mine report, but also the fullest possible interpretation of such data with reference to the mine's present status and future prospects. Of course, there is a large class of mines, falsely so called, whose shares are sold widely over the country, as recently pointed out by Mr. Merrill in these columns; and one of the most difficult tasks that confronts the Society in its campaign for the square deal to the public is that of enlightening the people on the distinction between a mine and a mere prospect. As I understand it, however, the Society is developing the less refractory vein first and the one that seems to promise more speedy returns, namely, the relations of the real going mine to its stockholders.

Surely it is to the interest of the mining industry in every way, and particularly as regards its standing in the public estimation, to combat the prevalent idea that mining is but an aggravated, although somewhat picturesque, form of gambling. The sooner a mine comes to be known and dealt with as a tangible asset the better for all concerned in real mining. This category, of course, does not include the professional speculator and inflator. These are the parasites of the industry; and parasites are not

only a source of discomfort—in civilized society they are a positive disgrace.

While we cannot yet weigh a mine and affix a price to it as if it were a packet of tea, still it is possible to arrive at a valuation on a perfectly rational basis. The public should not only know this, but should be able to take advantage of the results, with the clear understanding, of course, that such a valuation is only an estimate, and that various assumptions as well as known facts are involved in its computation. If a mine cannot reasonably be valued above \$500,000, and this fact is ascertainable on competent authority, there is little danger of the percolation of 'meteoric waters' into it to the extent of \$5,000,000; and such 'magmatic waters' as may have attended its intrusion into the upper strata of finance will be quickly eliminated by the normal processes of cooling and crystallization.

A good mine report should certainly include a statement of ore reserves, and the stockholder may also reasonably demand an estimate of the probable life of the mine. This information furnishes a basis for some sort of conception of the mine's actual value. Otherwise these are matters of little interest or importance to the public. It may be contended, however, that to stop at this point is to defeat, in a measure, the main purpose, so far as the investor is concerned. He will read of ore reserves and life of the mine with only a vague conception of their real significance; and he might well inquire, in the language of the street: "What's the answer?" It is no reflection on the average intelligence to say that few, even among competent business men, can properly comprehend such data. The services of an expert are required, and the stockholder may contend that he should not be obliged to employ an engineer to interpret the company's report for him. It may justly be said, however, that a demand for an annual valuation under present conditions approximates too closely a counsel of perfection, and would be little heeded, even if it did not arouse opposition to more moderate requests. Reform is not revolution, and any suggestion looking toward improvement on present practices must, in order to be effective, commend itself to hard-headed men of affairs who are in much closer touch with existing conditions than with ethical ideals. Hence, it would be a rational policy to make the present practice of the best companies the basis on which to build.

Of the three requirements that have been suggested for an ideal mine report, namely, (1) a statement of ore reserves, (2) an estimate of the life of the mine, and (3) a valuation of the property, the first is already met by various well-known companies, and it is not at all inconceivable that some of these might be persuaded to add the second also. We could then afford to wait long and patiently for the third.

With this much accomplished and a high precedent set for the less communicative, not to speak of the less righteous, organizations, a great step will have been taken toward the correction of the terrible abuses and the extermination of the pestiferous parasites with which the mining industry and the public

are now annoyed. All legitimate mining interests will surely assent to the desirability of these reforms. Is it too much to hope that enough of them to accomplish great results may be brought into agreement as to the most effective methods?

J. VOLNEY LEWIS.

New York, March 3.

Chances for the Prospector.

The Editor:

Sir—I have just received a newspaper clipping from Dawson about gold on the Firth river, up on the Arctic coast of this continent, but it has all been staked ere this, if it is worth it. Some 11 years ago a man came to me with a tale of gold on this same Firth river, when only he and one other knew of it, and I have three times been the recipient of this before-hand information. One quiet tip took me into a far-away country, where we found ancient diggings and a brass musket, but no gold. One was given me because I was a surveyor and the miners wanted to know where the boundary line was and this took me into the Yukon in the early days. The third I need not mention, as it is not of these trips I wish to deal. The long tramps and wasted years have taught me to discriminate, and have led me to have in my own mind convictions and feelings as to where the next gold strike and stampede would be. Such prophesying may sound foolish, but it comes from a knowledge of the mining business, and proceeds by a process of elimination.

In general, grant that every piece of territory on the face of the earth the size of a State has gold in it, provided it is mountainous and rocky. In turn each portion of the earth of that size and character has had its gold excitement—California, Idaho, Montana, Colorado, and others. Then eliminate all civilized parts of the earth that have probably been prospected, and see what is left. This will sweep away nearly the whole of the United States proper, Europe, and some more. I was in Georgia, North Carolina, and Tennessee in the years 1887, 1890, and in July of last year. Each time I was surprised to see the shafts, holes, and remains of wing-dams and hydraulic works those Southern mountaineers had made in the early days, 1830 to 1840.

Next, eliminate all the recent sedimentary regions, that is, the flat countries like the lower and middle Mississippi Valley. The next factor is accessibility and source of supplies. For instance, I label as inaccessible regions those where one is prohibited by government or is apt to be murdered by natives. This will eliminate more of the earth's surface, and one begins to get down to tolerably narrow confines. Then comes the most important elimination of all. Look up the history of the remaining territory carefully, going back to the days of the 'ancients', and you may learn some things that will show how important it is to do some discarding. For example: C. P. Campbell of Chicago told me that he had lately been working placer deposits in South America with poor success. Now Mr. Campbell is a good mining man, but he failed to read history. The ground was overgrown with trees some three feet in diameter,

and had the appearance of being virgin, but after installing expensive machinery he dug up the remains of old Spanish sluice-boxes, and quit. He says he can now identify the remains of ancient Spanish placer works by the peculiar shape of the surface, whether it is covered with a later growth of forest or not, and he has concluded that the Spanish Dons, each with a handful of armed retainers and a few hundred slaves, gave the whole of South America a good prospecting about the 17th century. So far as placer deposits and easy lode-mining are concerned, I should eliminate nearly the whole of South America.

I have at my home in Ohio seventeen large volumes in old English type, and very hard to read. They contain a history of gold mining in Africa up to the year 1750, and the information in those has led me to eliminate two thirds of Africa. Further to illustrate the process, let us consider Asia: Siberia was to me the worst disappointment. I was there a number of years ago, before the days of the concessionaires, when we were not wanted and took chances. If I had investigated the history of the region before I went, I could have saved myself some tramping. I will cite one passage: In a book called 'The Elements of Metallurgy', by J. Arthur Phillips, edition of 1887, it is said that "the remains of numerous mines have been traced by Gmelin, Lepechin, and Pallas on the southern and eastern border of the Ural mountains, and in them were found hammers and chisels of copper. These excavations are inferred to have been made by a nomadic people, probably the Scythians; and from the fact that no iron tools were found in any of them, we may conclude that these operations were before the conquest of Siberia by the Tartars, who effected the subjugation of that part of Asia about the year 150 B. C. * * * Smelting was effected by small furnaces made of red bricks. Gmelin found nearly a thousand such furnaces in the eastern part of Siberia. In the neighborhood of these furnaces were found large quantities of broken pottery, together with numerous heaps of scoria, which indicates that operations to a considerable extent had at some period been carried on in the same locality." And as for placer diggings, I will add that since the concessions many an American prospector has tramped for miles in Siberia and faithfully panned promising gravel that was probably worked some time B. C. This does not apply to the whole of it, but there are large areas to be eliminated.

It is a pity that some scientific society does not extract the information buried in history and compile it for the benefit of modern seekers after the king of metals. For the present it is best to keep out of the trail of the Queen of Sheba prospectors, the Spanish Dons, and the Portuguese explorers. What they, with their hordes of black slaves, left behind them can only be worked when we get the help of railroads and modern machinery.

On the other hand, even in seemingly hopeless countries, there are isolated tracts entirely unprospected, where the ancient gold-seekers were held back by hostile tribes. This accounts for some com-

paratively rich spots in Asia, South America, and Africa, profitable now on account of transportation and machinery, but they are not now and never have been bonanzas for the pioneers, or the lust for gold would have overcome the obstacles long ago, and the right to work would have been wrested from the savages, just as we forced the Sioux out of the Black Hills, and as the Spaniards subdued the Peruvians. When at the age of eighteen I first started out prospecting, I thought that nearly the whole world needed exploring, but I have since concluded that our forelopers, black, white, and yellow, have left but few corners untouched.

So we may eliminate the possible places for new discoveries of the magnitude of Ophir, Peru, the Gold Coast, California, Dawson, and Nome, down to a few thousands of square miles. And gold is not found by a dream. When it is discovered, it is because some man is there and digs it up. Of those who do the digging and discovering, that is, the true prospectors, those who can and will do nothing else, there are, in my estimation, only about 5000 in the world. I know this about as well as an old-time tramp printer could tell you how many other tramps there were on the road; a guess, but a fair one. Of the half-way prospectors there may be probably half a million. Falling back upon farming between seasons, they never get far from home and don't count heavily. In this connection I admit that it is not always the experienced prospector who makes the discovery, for it has often been some greenhorn drawn into the excitement, for whom they blazed the way and showed *how* at least, if not exactly *where*.

It is an interesting question what this bunch of dyed-in-the-wool prospectors is doing, and which way they are heading. With the present living members of the fraternity one can have but little more touch than with the dead and their secrets. We may learn that a few of them are heading in some promising direction—toward some really unexplored country. A letter from one or another of them now and then tells where a handful of them are. Thus I can keep tab on a few, but what their hopes and prospects may be is a question a 'cheechako' might ask, but a 'sour-dough' never answers.

H. H. EDGERTON, Jr.

Laws, Inyo County, California. March 6.

Ozone is best prepared by the silent discharge of high-tension electricity through perfectly dry air. There are many devices for ozoning air, most of them being adaptations of the Siemen's ozonizer, familiar to all students of physics. The ozonizer at Wiesbaden was designed by Siemens and Halske. The air drawn into it is dried by contact with hygroscopic substances, as CaCl_2 , or, preferably by refrigeration in a chamber cooled as in the freezing machines. The voltage required to operate this instrument is about 80,000, and the generator absorbs 1 hp. The amount of ozone produced varies from 13.5 to 27 gm. per hour, the rate of production depending on the dryness of the air which enters the apparatus. This quantity of ozone will purify from 2200 to 4400 gal. of water.

HOW IT STRIKES AN AMERICAN.—II.

Written for the MINING AND SCIENTIFIC PRESS
By T. LANE CARTER.

In shaft sinking, they maul faster, if not cheaper, on the Rand than in America. As conditions vary so little out there, one shaft being about the same as another, they have acquired so much experience as to have their methods of shaft sinking down to a fine point. But faster drifting is accomplished in America. I could pick out remarkable records in drifting on the Rand, and could give instances of poor work in development in this country, but as a rule they

from the Rand section. In Africa a manager will sink a winze every time in preference to raising, while in America very little winzing, or winze sinking, is done, raising being the method adopted to get connections through. Labor for cleaning up the dirt is cheaper in Africa; therefore better work can be done there in winzing than in America.

For years the question of health among the underground workers has agitated people on the Rand. Commissions have been appointed to enquire into it, and many papers and figures bearing on the subject have been published. Laws and regulations have been passed to improve the health of the workers.

For instance, it is now illegal to use a percussion machine in the mines useless sprays are employed to keep down the dust. Before shoveling dry ore, water is supposed to be spread over it to keep the dust down. From this it is seen that the dust problem in mines has been seriously tackled in the Transvaal.

Much attention has been given, and is being given, to the question of ventilation of the mines on the Rand. For some time past they have been debating whether 0.25 or 0.30 CO₂ should be the permissible limit in mine air. The question whether artificial ventilation should be put in has been discussed. All kinds of tests and analyses of air from the mines have been made at the Government laboratory. Explosives have been investigated, and the gases therefrom, in an attempt to improve underground workings conditions. A sharp outlook is kept for ankylostomiasis, or miner's worm, and other diseases which might attack the underground worker.

I found nothing like this solicitude over the health of the miner in America. After talking with medical men I came to the conclusion that there has not been the same cause for alarm in the mines of America as in the Transvaal, for the health here seems to have been better. The ravages of miner's phthisis or silicosis, which has played such havoc on the Rand, has never appeared to the same extent in America, according to the medical men I talked with. In no

The Camp Bird Mills, Near Ouray, Colorado.

State did I find people exercised over the high death-rate of underground men, as they have been in the Transvaal, and this in itself is a proof that the mortality in the mines could not have been excessive. In no metal mines did I find artificial ventilation used to any extent, although it struck me that better use was made here of natural ventilation than on the Rand. Indeed, natural ventilation here is better because of the 'lay of the land'. Most of our mines are in mountainous country, where the difference in levels between two shafts may be such as to give a large motive column for the air. On the Rand the shafts are nearly on the same level. From what I

State did I find people exercised over the high death-rate of underground men, as they have been in the Transvaal, and this in itself is a proof that the mortality in the mines could not have been excessive. In no metal mines did I find artificial ventilation used to any extent, although it struck me that better use was made here of natural ventilation than on the Rand. Indeed, natural ventilation here is better because of the 'lay of the land'. Most of our mines are in mountainous country, where the difference in levels between two shafts may be such as to give a large motive column for the air. On the Rand the shafts are nearly on the same level. From what I

could see, they are not worrying much over here about the dust problem. The use of drills requiring water for their operation prevents dust where this machine is used. How to account for the high death-rate on the Rand, as compared with America, is a problem. Several possible reasons have occurred to me, to explain why it is that in the Transvaal the health of the underground workers has in the past been unsatisfactory. From what I could ascertain, the health of the American miner has in the past ten years been better than in the Transvaal. Why is this? In the first place, the negro race in America does scarcely any mining. Black men have a distinct racial tendency to pulmonary complaints. If only white men were employed in the mines of the Transvaal, under exactly the same conditions, the death-rate would go down. But the chief reason for better health among American miners in the past (and mind you, I am speaking more of the past ten years than of the present, for the new regulations will greatly improve the health of miners on the Rand) is found in the fact that the number of men employed underground is proportionately less than in the Transvaal. As a rule the veins in America are wider than in the Transvaal, and into this larger space fewer men are crowded. It is the same problem as an assembly hall. For one or two people the air is ample, but let a crowd pack the hall, and they will smother or become affected unless you resort to artificial ventilation.

Now that air-drills are coming into more extensive use on the Rand, it is probable that the number of men employed underground will be reduced. Judging from American experience, it seems that in the past the quantity of air in some of the mines on the Rand has been insufficient for the number of men. Had there been half as many in the mine, the quantity of air would have been sufficient. Another reason for the greater mortality on the Rand in the past exists in the character of the dust. It is sharper, and therefore more destructive on the lungs than the dust generally found in the mines of America. The Transvaal mines are materially drier. It speaks well for the Rand that the scientific societies and the medical men should be giving the question of the health of miners so much attention, and I should like to see the mines of America show as much solicitude for the health of employees. Although our conditions are more favorable, they can be improved.

In one thing the Transvaal is far and away ahead of America, and that is mining law. As a matter of fact there has never been a mining district where law in general has been better observed, than on the Rand. At one time law in the 'wild West' was unknown, and even today are found mining centres where the only use made of the laws appears to be to break them. On entering the fine offices of several large mining corporations of this country, I was struck by a conspicuous sign with the ominous words, 'Legal Department'. The mining industry in America keeps alive a lot of 'mining lawyers' who could not live under the simple clear law of the Transvaal. A special line of mining engineering here is the giving of expert evidence and advice in

legal fights between contending parties, and the man of persuasive eloquence and immense assurance has a wonderful knack of inducing a judge and jury to swallow a lot of "geological delirium tremens" (to use an expression of T. A. Rickard's). The fear of some outside persons or corporations trying to prove under the law of extra-lateral rights that your mine really belongs to them is a nightmare. To prove to judge and jury that the mine really belongs to you, becomes at times a more difficult problem than the running of the mine. The American law is unfortunate, but it was from our sad experience that the Transvaal was able to devise her superior mining laws. The 'law of vertical planes' in the ownership of claims in the Transvaal, does away with all rows over extra-lateral rights. The mining law there is in many respects so clear and simple that the chances for law-suits are small. Therefore the expert legal mining advisor, as we know him in America, is there unknown. Many engineers have declared that the Transvaal Government is too paternal; that it tries to tell you in too great detail how to prevent accidents. I have studied both systems—that in which the mines are run with scarcely any governmental interference, and those in which there is probably too much, and I must say I prefer the mining regulations of the Transvaal to the lax methods seen in some of our States. Given a competent conscientious manager, and the safety of the men will be guarded, even though it cost a lot of money. But the strict regulations of the Transvaal soon reveal the man who will not look after the safety of his men. The high accident-rate on the Rand is generally adduced to prove the futility of the regulations, but it must be remembered that the labor used is ignorant and stupid. Were the mining regulations of the Transvaal less thorough than they are, and the common American system of *laissez faire* adopted in the Transvaal, the death-rate from accidents would easily be twice what it is today, on account of using so many negroes.

I have been struck by the general spirit of lawlessness apparent in many of the mining districts of the United States. The more settled sections, like the Lake Superior region, are as law-abiding as any other mining centre of the world, but in other parts the laws seem utterly disregarded. For instance, Sunday closing laws for bar-rooms are passed, but the bars disregard them and throw their doors open as wide as ever. In the Transvaal a law is not a dead letter. Any gentleman who does not see his way clear to obey it can either go to jail and live at the Government's expense, or pay a fine. The carrying of concealed weapons is by no means as common there as in America. A person must get a license to have a fire-arm in his possession. In this way the number of revolvers in the community is kept down, and in consequence the 'shooting scrapes', which are such a feature of many American mining camps, are uncommon. The promiscuous sale of fire-arms in America is unfortunate, and I believe the Transvaal system of registration (if carried out) would reduce the number of murders committed.

A new word has become common in American min-

ing during the last ten years, namely 'high-grader'. In Africa during the war they brought in a word for the same offense, namely 'commandeer'. These are polite words for thief. The man who steals gold from a company has a far harder time of it in the Transvaal than in America. In some places many miners seem to think that to steal specimen-rock from underground is no offense, but for a man in the mill or cyanide works to steal gold is reprehensible. The precious metal, it would appear, does not really belong to the company until it gets into the mill-bins. In many districts it seems difficult to get a conviction against a 'high-grader', even when the offense is proved, because the jury is afraid of losing trade in the community in case they convict the thief. How to stop 'high-grading' at many Ameri-

Anaconda, Montana. One is struck by the extensive use of labor-saving devices at this great plant. As there is practically no metallurgical work in South Africa save that in the extraction of gold, few comparisons can be made between the two countries in this regard, but a pertinent one may be made between the cyanide practice of the Rand and of the United States. The Transvaal is justly proud of its work in the cyanide process. This is the Rand's great contribution to the metallurgy of the world. A visitor from South Africa naturally goes to a plant like that at the Homestake, South Dakota, expecting to find a blind imitation of South African cyanide practice, which he naturally considers the best. But he discovers that South Africa has not been followed blindly. Conditions at the Homestake are different

On the Rand.

can mines is a problem that greatly worries the management. Much is being done to reduce the evil, but more can be done by the co-operation of all the mines in one district in adopting rigid rules. It should be impossible, for instance, for a known 'high-grader' to get work again in the district where he had committed such an offense.

Precautions are taken by the management of gold mines where specimens of 'visible gold' are common, to prevent 'high-grading', but it goes on to a large extent. On account of the scarcity of 'visible gold' in large quantities on the Rand, 'high-grading' is practically unknown. But I insist that the law in the Transvaal against stealing is more certain than in America. In the Transvaal the leakage of the precious metal is from the mill and cyanide works, not from the mine.

What a wonderful country America is for its metallurgy! There is no more impressive industrial sight in the world than the great copper smelter at

from those in Africa, and they have worked out their metallurgical problem with skill and success. I do not remember anything finer in my trip through the States than the metallurgical work at the Homestake mine. I was struck by the fact that the ore there is not as simple a cyanide proposition as on the Rand. Homestake practice differs in many respects, among which are the treating of the sand in the same vat in which it is filled from the battery; the prolonged use of compressed air to aerate the sand and slime, a large compressor being necessary for this; the use of zinc-dust and filter-press for precipitation of the gold-solution as opposed to the use of zinc-shaving and boxes on the Rand; the use of Merrill presses in the treatment of slime as opposed to the decantation process of the Rand; the discharge of sand and slime by water-sludging, in contrast to the Kaffir and shovel method on the Rand.

The good work being done for American mining by the mining schools is also manifest. Much of the

recent advance is due to these. Were I inclined to criticize, I would say that there are too many schools of mines in the United States. A thoroughly equipped mining college costs a mint of money, and every one of the schools could do better had they more ample funds. These schools have raised, and are raising, the tone of mining. Not many college graduates will be found among the blackguard 'wild-cats', and thieves—those camp-followers that infest the mining army all over the world. Technical graduates generally 'make good'. While on the subject of mining education, I think it no more than fair to mention the good work that correspondence schools, especially the Scranton school, have done for the earnest young men of this country who are compelled to work in the mines, but who nevertheless have a desire to know the scientific principles upon which mining is built. Many a young fellow in America and in the Transvaal has been able to improve his position through knowledge thus acquired. In spite of the good work the mining schools have done and are doing, there are some old 'hay seeds' who say, "Give me a practical man every time; one who started in the business when he was a boy." Even in this enlightened age many people think that anyone can run a mine; that, like poetry, the running of a mine is a gift. They do not seem to realize that a successful dentist, for instance, is not the man to superintend a mine. He might be a good tooth-carpenter, but that does not make him a mining engineer. In my tour I saw some awful mistakes made by these 'practical' men, the dentists, lawyers, physicians, and ministers of mining. One instance especially comes to mind. It was a case of a really good gold-prospect, which I believe will some day become a successful mine. The man in charge is a cowboy by profession. His preparation for his present job consisted in passing the smoke-stacks of a mine for a number of months. He calls himself a 'practical' man. No 'theory' for him, or the men who hold the prospect. Somehow or other he was sent into the wilds to manage this property, and already has almost closed it down. One of his most brilliant feats is the driving of an adit 1100 ft. long through hard rock to get 'backs' only 100 ft. The adit is about 10 ft. below the level of the mill, and all the ore which comes from the opening must be shoveled up-hill. After such examples as this, one is inclined to believe in the Transvaal scheme of making it compulsory for a mine to have a 'certificated manager'. The complete failure of a good mine by bad management might doom a whole district to undeserved idleness.

It will, I am sure, interest American readers to know that the Transvaal has made a splendid start in the important work of technical education, and that there is a mining school at Johannesburg where the young men of the Transvaal can get a mining education before they begin their life work. In connection with this technical college there is an excellent system of night-schools, where the miners and apprentices may learn something of the theory of their work.

There is one department of the Government service

to which American mining owes an inestimable debt of gratitude, and that is the Geological Survey. What a help the professional papers on the different districts are to the stranger, when he arrives in a new mining centre and wishes to gain accurate information about the geological conditions! There is no finer government institution in the world, nor one from which greater good has been derived by the State, than the United States Geological Survey. The Geological Survey in the Transvaal has rendered good service, but there remains a great deal more to be done. If it does its work as thoroughly and successfully as the Survey in this country, mining in the Transvaal will be enormously benefited.

In conclusion I wish to comment upon the kind reception and hospitality shown me at every place I visited. The idea prevails that secrecy is the common policy at the American mines, but I must say that my experience does not bear this out. I was taken over mines and works with as much freedom as is always shown the visitor to the mines of the Rand.

MONEY FOR THE GEOLOGICAL SURVEY.

The work of the United States Geological Survey is carried on by means of appropriations made each year by Congress, chiefly in the act providing for "sundry civil expenses of the Government," popularly known as the sundry civil act. The sundry civil act passed by the Congress which has just adjourned appropriated for the Survey for the fiscal year 1909-10 the sum of \$1,407,390, specifying that it be applied to the following purposes:

Geologic surveys	\$ 225,000
Chemical and physical researches.....	20,000
Mineral resources report	75,000
Topographic surveys	350,000
Forest reserve topographic surveys	75,000
Water resources investigations	100,000
Structural materials investigations	100,000
Fuel testing investigations	100,000
Mine accident investigations	150,000
Geologic maps (printing and engraving) ..	100,000
Preparing illustrations for reports	18,280
Books for library	2,000
Statutory and temporary salaries	88,760
Mine inspectors' expenses	3,350

\$1,407,390

An appropriation of \$90,000 for the investigation of Alaskan mineral resources by the Geological Survey was carried in the urgent deficiency act. Other appropriations for rent of offices in Washington and for publications make the total amount provided for the work of the Survey about \$1,700,000.

Invar is the name of a new alloy brought out in France, which has the valuable property of having practically no expansion; it is not magnetic, and does not rust. Nickel-steel is the base of the alloy, and up to 20% of nickel the expansion is about normal. It then increases up to 24%, reaching a minimum at 36% nickel, then rising and taking the normal expansion for a 50% alloy. It is the 36% metal which has the desirable property of having the expansion reduced almost to zero, being 17 times less than that of steel, and about the same as for melted quartz.

TRANSPORTATION FACILITIES IN ALASKA
AND THE YUKON.

Written for the MINING AND SCIENTIFIC PRESS
By W. M. BREWER.

Notwithstanding that the first great rush into these territories commenced in 1897, but little is known to the outside world of the means of transportation which have been developed. To reach any port along the Alaskan coast, there are five regular lines of steamships controlled by the Pacific Coast S. S. Co., Alaska Steamship Co., Alaska Coast Co., Shubacker & Hamilton, and the Canadian Pacific Railway. All of these, with the exception of the last named, have their home port at Seattle, while the C. P. R. conducts its coastwise service from Victoria as a base. Through connections in Seattle, however,

visit any point today along the Alaskan coast and feel confident of comfort and safety.

The following table of distances between ports on the southerly portion of the Alaskan coast will serve to show the extent of the coast-line, and when it is considered that in this table only a portion of the coast-line is taken into consideration, and that the Aleutian archipelago, Bering Sea, and the Arctic Ocean coast-lines are much greater, the vast extent of this western possession of the United States may be realized.

TABLE OF DISTANCES.

Port.	Miles.
Seattle to Juneau	899
Juneau to Sitka	160
Sitka to Yakutat	229
Yakutat to Katalla	175
Katalla to Orea	114
Orea to Cordova	3
Cordova to Ellamar	51
Ellamar to Fort Liscum	22
Fort Liscum to Valdez	3
Valdez to Latouche	88
Latouche to Seward	58
Seward to Seldovia	147
Seldovia to Kadiak	117

Map of Alaska.

it is enabled to carry passengers to and from that port by breaking the voyage in either direction at Vancouver or Victoria. The ports of entry along the Alaskan coast to which regular steamship service has access are as follows, from southeast to northwest: Ketchikan, Wrangell, Petersburg, Juneau, Haines (for Ft. Seward), Skagway, Sitka, Yakutat, Katalla, Cordova, Orea, Ellamar, Valdez (also Ft. Liscum), Latouche, Seward (Resurrection Bay), Seldovia (Cook's Inlet), Kadiak, Dutch Harbor, St. Michael, and Nome. In addition, there are a large number of ports at canneries and mining camps, served by small vessels that make their headquarters at Ketchikan, Juneau, Valdez, Seward, St. Michael, and Nome. As a matter of fact, at the present time, the service rendered by steamship companies and individual owners of vessels in the various mosquito fleets, is excellent for all needs of travel to Alaskan ports. Of course, the service has not attained such perfection as to place it beyond criticism, but one may

Elias the portion actually belonging to the United States is represented by a narrow strip 30 miles wide back from the coast-line. Owing to these geographical conditions, it is almost impossible to discuss questions of transportation without considering the two territories and the conditions in both.

The first attempt at railroad-building in this portion of the world was made in 1898 when a company of capitalists began the construction of what is known as the 'White Pass Route,' from Skagway, at the head of Lynn Canal, into the interior. It is not necessary to refer to the difficulties attending the construction of this line from Skagway in Alaska, to White Horse, in the Yukon Territory, a distance of 112 miles. It is sufficient to say that it was looked upon at the time as a costly undertaking, and while it presented no complicated engineering feat, yet it is a monument to the determination, energy, and courage of its incorporators. Railroad construction from the coast into the interior can only be success-

fully carried out from certain ports and through certain passes in the coast range. These are Skagway, Haines, Katalla, Cordova Bay, Valdez, and Seward. The reason for this limited access to the interior is due to the obstacles presented by the coast range, either because of extensive glaciers or of precipitous mountains with passes at high elevations too near to the coast to afford the engineers an opportunity to locate lines with moderate grades.

Up to this time only four of these ports have been actually utilized as terminals for railroad lines, namely, Skagway, for the White Pass route; Katalla, for the lines of railroad into the Bering Lake coal-fields; Cordova, for the Copper River & Northwestern; and Seward, for the Alaska Central. From the port of Valdez attempts have been made that could hardly be called serious. The only other gateway into the interior likely to become the point of departure for a railroad is Haines Mission on Lynn Canal. From this point railroad construction following generally the route of the old Dalton trail up the Porcupine river and thence northerly, could be satisfactorily carried on and would be the means of opening up a large unexplored territory. It would afford an opportunity to open up with little effort the known copper-bearing regions of Rainy Hollow, about 40 miles from Haines Mission, and around the head of the White river, about 300 miles farther to the northwest. A line of railroad constructed from Haines Mission, following the route suggested, would develop an entirely new country and would afford an excellent opportunity for thorough exploration of the water-sheds of the Porcupine, Alsek, and White rivers in British territory, without interfering with the proposed route of the Copper River & Northwestern railroad, at present being built to open up the copper mining district in what is known as the Copper River country. Neither would it affect the present line of railroad from Skagway to White Horse. The section of country around the head of the White river is most easily approached by way of the stage road built by the Canadian Government about three years ago from White Horse to Kluane lake, thence by trail into the White River district.

Until after the boundary line was formally established, it was supposed that the copper prospects discovered at the head of the White river were in American territory, but they are now known to be on British soil.

The following is a list of the mileage and terminals of Alaska railways up to January 1, 1909:

Seward Peninsula.	Miles.
Seward Peninsula Railway, Nome to Shelton...	80
Paystreak to branch S. P. Railway.....	6.5
Council City & Solomon River Railroad, Council to Penelope Creek	32.5
Wild Goose Railway, Council to Ophir Creek...	5
Fairbanks.	
Tanana Valley Railroad, Fairbanks and Chena to Chatanika	46
Kenai Peninsula.	
Alaska Central Railroad, Seward to near head of Turnagain Arm	53
Copper River.	
Copper River Railroad, Cordova to Childs Gla-	

cier (September 17)	47
(Probably 11 miles have been built since September 17. Same railroad at Katalla, where there has been some work done by a rival company, has built between three and four miles. At Valdez a few miles of track of the Alaska Home railway were laid in 1907.)	
White Pass.	
White Pass & Yukon Railroad, Skagway to White Horse	20.4
(Terminal at White Horse, Yukon Territory.)	
Yakutat Bay.	
Yakutat Southern Railway, Yakutat to Situk River	9
(Portions of the Council City and Solomon River and of the Alaska Central are out of repair and not in use.)	

The greatest interest in railroad building centres around the Copper River & Northwestern railroad with its terminus at Cordova. This is being built by contract by M. J. Heney, who constructed the White Pass road, while E. C. Hawkins, who was the first general manager of the White Pass road, is general manager. These facts are sufficient to insure rapid progress, and unless unforeseen accidents should occur there is no question that this railroad will be completed to the mouth of the Chitina river by the fall of 1909. During the present season these gentlemen have announced that the railroad will be opened to the head of Abercrombie rapids where connection will be made with steamers that will navigate the Copper and Chitina rivers as far as the mouth of the Nizina.

The section of country known as the Copper River country, which includes the Kotsina, Kushkilina, Lakina, Nizina, all of which head in the range of mountains of which Wrangell and Blackburn are the highest peaks, has, for the past ten years, been one of the most attractive to the prospectors who were looking for copper-bearing ore. Their attention was first called to it by the occurrence of masses and nuggets of native copper which were found by prospectors exploring for placer gold. But it has been difficult of access. Heretofore, exploration was attended by great hardships, as well as excessive cost for freighting supplies in from Valdez. This necessarily retarded progress, but with reasonable transportation facilities a considerable tonnage of copper should be shipped within the next two years.

The railroads projected from Katalla to the coal-fields around Bering lake have had practically no work done on them since the fall of 1907. Although this is the natural outlet from those coal-fields it is on the coast with an open roadstead, which could be made into a harbor only by the construction of break-waters at an expense of millions. For this reason, it is generally understood that a branch of the Copper River & Northwestern railroad will be built from the crossing of the Copper river down the east side, thence easterly to the coal-fields, and that the product will be hauled that way to Cordova. The development of this coal-bearing area will undoubtedly have a material influence upon the future of that portion of Alaska, because, if as is contended, these coal-fields contain good

coking coal, it will be feasible to erect smelters in the vicinity of Cordova and treat the ores produced from that region at home instead of shipping to the smelter at Ladysmith on Vancouver island or at Tacoma. During 1905 the interest in railroad building in Alaska centred almost entirely in the operations of the Alaska Central, then being constructed from Seward on Resurrection bay, across the Kenai peninsula and up the Susitna river, with its proposed northern terminus near Fairbanks on the Tanana river, but financial difficulties and litigation have since then caused a suspension of active construction, and the terminus is about 55 miles from Seward. This road, if continued, will tap the coal-

Part of the Yukon Territory, Canada.

fields on and near the Matanuska river, where it is claimed a quality of coal occurs in quantity which is as good as that developed around Bering lake. Until railroad construction has progressed sufficiently to bring these coal-fields and the known copper-bearing area in the Copper River district to market, this interior must necessarily remain dormant, except so far as gold-placer mining operations are concerned. Therefore, it is undoubtedly important that encouragement should be given to the construction of at least three main lines of railroad from the coast into the interior, from Haines into the British Yukon, from Cordova to the Copper River, and from Seward into the Matanuska coal-fields and the territory drained by the Susitna river. So far as wagon roads are concerned, the Government of the British Yukon has been enabled, because

of its policy and method of producing revenue, to construct a much greater mileage, and much better roads, than are seen in the United States territory, but if the proposed policy of the Road Commission in Alaska is adopted by Congress and sufficient appropriations made, there should be within the near future a main trunk road from the coast through to Nome, which will enable prospectors to transport supplies at a reasonable cost and maintain camps on various rivers and streams from which they can branch into parts of the country that today are unexplored.

Monel metal consists primarily of three parts of nickel to one of copper, this being the natural proportion in which these metals exist in the deposits of nickel ore in the Sudbury district, Canada. Throughout its manufacture the alloy acts as a single metal, and while proof is incomplete, evidence shows that in these proportions nickel and copper have a relation to each other known as eutectic. Like steel, this alloy absorbs carbon, and its physical properties are profoundly influenced not only by the percentages of carbon, silicon, etc., but by the heat-treatment it receives. A standard analysis of monel metal is:

	Per cent.	
Nickel	68	to 72
Iron	0.5	to 1.5
Sulphur		0.014
Carbon	0.073	to 0.15
Copper to balance.		

The metal is silver white; takes a brilliant finish; in rolled sheets on being heated it becomes coated with oxide which is resistant to acids, no loss of weight being shown after 40 days service in pumping 40% sulphuric acid; it melts at 1350° C., can be rolled between 900 and 1200° C., can be finished hard or soft like sheet-copper, and can be drawn into wire, soft and pliable, 0.004 in. diam., making excellent material for filter cloths. Its tensile strength is as high as 9000 lb. per square inch.

Electrolytic detinning of scrap iron by a process invented by Meredith Leitch is done as follows: A caustic soda solution is withdrawn by means of a pump from the detinning bath at a point near the bottom, where it is coolest; it is forced through a boiler, where it is heated; and returned to the detinning bath at a point near the top, but below the surface of the electrolyte. The advantage over an over-flow arrangement is that with this method of circulation the caustic soda does not come in contact with air, which would result in the formation of a carbonate. A second device consists of a U-shaped basket with perforated walls, having in its interior a conveyor-chain carrying tin-scrap through the cell. On both sides of the basket are cathode plates. The whole is contained in a tank filled with electrolyte. The tank is lowered at certain intervals, the electrolyte run off, the tin powder removed from the cathode plates by scrapers, and the apparatus cleaned.

In dies and die-blocks an iron-titanium alloy gives tremendous resistance to shock and consequent large increase in the life of such castings.

CYANIDATION OF PARRAL SILVER ORES.

By H. T. WILLIS.

One of the pioneer mines in the application of cyanidation to silver-gold ores was the Creston-Colorado mine of Minas Prietas, Sonora, Mexico. Until then the extraction of the silver-content of ores was simply incidental to the recovery of the gold. The Creston-Colorado installed a 125-ton plant for the treatment of sand from the concentration mill, which had succeeded the earlier pan-amalgamation plant. Good results followed the cyanidation of the sand tailing by applying gold extraction methods and by increasing the period of treatment to about 15 days, but at that time they had no way of treating the slime, which they therefore impounded in storage dams.

Other mines in Mexico followed the example set by the Creston-Colorado, with varying results, and from that time cyanidation of silver ores commenced. South African and West Australian practice was then in the forefront and their methods have since been applied, with modification, to the treatment of Mexican silver ores. Mexico has always been, and is today, the only country where silver ores have been treated to any considerable extent, and it is there that the cyanidation of silver ores has been developed to its present high state of perfection.

In 1904 the Creston-Colorado Co. remodeled the entire plant and installed a slime plant of 100 tons capacity. The capacity of the mill and cyanide equipment was then 200 tons per day, and it was the most modern and complete in Mexico as well as one of the best of its kind in the world. It is today one of the best in Mexico. The fact was demonstrated that, with modern methods and equipment, silver could be treated as successfully as gold ore.

The practice at the Creston-Colorado plant during my connection with it, up to May 1905, was briefly as follows: (1) the ores were crushed in Blake crushers; (2) reduction by stamps in cyanide solution; (3) re-grinding to 60-mesh by Huntington mills; (4) hydraulic classification of sand and slime; (5) leaching of sand for 15 days with cyanide solution of various strengths; (6) slime agitated 18 hr. with strong cyanide solution; (7) slime residue filter-pressed; (8) all solutions precipitated on zinc; (9) precipitate filter-pressed, dried, and melted into bullion.

The value of the ore treated was 13 oz. silver and 0.75 oz. gold. It was considered exceptionally refractory material, but the extraction averaged about 87%. Since 1904 the improvements in the cyanidation of silver ores have been chiefly along the line of making and filter-pressing slime, for it has come to be understood that in order to secure the best extraction from silver ores they must be reduced to a slime and thoroughly agitated, thus requiring filter-presses to separate the precious metal-bearing solutions economically. The most modern practice is to reduce the ore to a slime at once.

The first plant in Mexico to reduce all the ore to slime was at the Dolores mine, in the State of Chi-

huahua, in 1906. Under my direction, the results obtained exceeded the most sanguine expectations. The ore was worth about \$50 per ton, and the extraction was about 95% of the silver and 97% of the gold. These were averages for long periods. That the treatment of silver ores is of vital importance to Mexico may be readily understood from statistics which show that Mexico produces more silver than any other country in the world.

During the year 1907 Mexico's silver production was valued at \$43,814,896, as against \$38,445,236 for the United States. Mexico's production of gold for the same year was only \$17,820,000, and of copper, 61,127 metric tons, which, at 20.661c. per pound, the average price for the year, is \$27,842,884.

As in the case of gold ores, cyanide in the treatment of silver ores is not of universal applicability, but it is safe to say that fully 90% of all the silver ores in the country, not suitable for smelting, are adapted to successful treatment by this process. In order to give some idea of the number of silver cyaniding plants in Mexico, the following partial list is submitted:

Name.	District.	State.	Capacity, tons per day.
Dolores	Temóscohic	Chihuahua	100
Concheño	Ocampo	Chihuahua	150
Palmarejo & Mex.	Chinipas	Chihuahua	200
Pinos Altos	Pinos Altos	Chihuahua	200
Candelaria Consolidated.	San Dimas	Durango	30
Siánori M. & M.	Siánori	Durango	20
Mex. Con. M. & S. Co.	Guanaceví	Durango	150
Guanajuato Con.	Guanajuato	Guanajuato	250
Guanajuato Red. & Mines.	Guanajuato	Guanajuato	250
Guanajuato Amalg.	Guanajuato	Guanajuato	300
San Próspero	Guanajuato	Guanajuato	100
El Cubo	El Cubo	Guanajuato	50
Peregrina	Guanajuato	Guanajuato	250
Pinguico	Guanajuato	Guanajuato	250
Cia. Beneficiadora	Pachuca	Hidalgo	100
U. S. Mining	Real del Monte.	Hidalgo	250
U. S. Mining	Pachuca	Hidalgo	250
San Rafael	Pachuca	Hidalgo	120
La Union	Pachuca	Hidalgo	125
Pachuca Tailing	Pachuca	Hidalgo	150
Amparo	Etzatlán	Jalisco	240
San Rafael	Ameca	Jalisco	25
Las Dos Estrellas	Tlalpujahua	Michoacan	625
Palmarito	Cullacán	Sinaloa	200
Creston-Colorado	Minas Prietas.	Sonora	200
Red Mountain	Santa Ana	Sonora	200
Alma	Vievas	Zacatecas	60
El Bote	Zacatecas	Zacatecas	150
San Rafael	Zacatecas	Zacatecas	100
San Cristóbal	Zacatecas	Zacatecas	80

The total capacity of the above list amounts to 5165 tons per day, and constitutes only a portion of the silver cyanide mills of the country.

The different classes of Parral ores adapted to this treatment may be divided as follows: (A) clean silicious silver ores amenable to direct cyanidation, yielding pure silver bullion; (B) silicious silver ores containing a small amount of sulphide, amenable to concentration followed by cyanidation; (C) base sulphide ores requiring concentration and cyanidation of the tailing. Extractions of 80 to 95% can be obtained from these ores, depending upon their character and value, but all could be treated

at a profit under favorable conditions. I do not mean to say that all grades of ore can be treated profitably, for that is a function of the sort of treatment, which in turn is dependent largely upon the cost of power. The cyanide process has been employed so long for the treatment of tailing and low-grade ore that it has come to be accepted generally that the process is applicable only to the treatment of low-grade material. Such a condition is unjustified by statistics. For example, if an ore assaying 500 gm. silver yields 85% extraction and the tailing assays 75 gm., then it has been found that the same class of ore, with the same mineralogical content but assaying 1000 gm. silver will yield, say, 90% extraction and the tailing assays about 100 gm. In other words, the percentage of extraction obtained from any given ore is not constant, but is dependent largely upon the grade of ore treated, and the value of the tailing after treatment will be more nearly constant than the percentage of extraction. In the same way, 1500-gm. ore might be expected to yield 95% extraction.

It may be of interest to estimate the cost of treating Parral ores. The most modern plant would be about as follows: (1) Gates coarse rock-breaker to 2½-in. size; (2) Gates fine rock-breaker to 1-in. size; (3) heavy stamps (1500 lb.), 18-mesh screens or coarser, for class A ore, crushing in cyanide, weak solution, low discharge; (4) Wilfley concentrators (for class B); (5) Wheeler type grinding-pans (60 mesh); (6) tube-mills for sliming to 200-mesh; (7) air-lift agitation tanks of Pachuca type; (8) Ridgway or Butters slime filter-presses; (9) zinc precipitation, oil-burning tilting furnaces, clean-up presses, etc. Such a plant would cost, erected complete and equipped with electric motors, from \$10,000 per ton for a plant of small capacity to \$500 per ton for one of large capacity, of say 500 tons per day.

It is difficult to estimate cost of treatment without actual data upon the particular ore to be treated, and of course the ore of any particular mine should be tested separately, as each one will be different from every other and require slightly different treatment and equipment to obtain the best results.

As an example of what might be expected, assume that a large mine is supplying 500 tons per day to the mill; that the water was supplied by the mine and charged to mining expenses; and that power was available at 1 cent per hp-hr.; then the cost per ton of ore might be about as follows:

Cyanide, 1.5 kilos, at 34c.	\$0.5100
Zinc, ¾ kilo, at 20c.	0.1500
Lime, 6 kilos, at 0.275c.	0.0145
Power, 1.75 hp., at 24 hp.-day	0.4200
Steel, pebbles, iron, etc.	0.1600
Lubricants, lamps, etc.	0.0125
Melting bullion and supplies	0.0500
Foreign salaries and labor	0.1380
Native salaries and labor	0.1045
One-half general manager's salary, at \$10,000 per year	0.0280
One-half general office expenses	0.0200
Sundries	0.0050
Total charges	\$1.6125

In addition to the above cost of treatment must be added the following variable expenses:

Mexican Federal tax, minimum	2.5
State tax	1.5
Additional Federal tax, 20% of 1.5%	0.3
Assaying, transportation, and realizing	1.7
Total variables	6.0
Suppose the above mill were treating ore assaying 500 gm. and obtaining an extraction of 85%, then the total cost would work out as follows:	
85% of 500 gm.	425 gm.
425 gm. (Ag. at 55c. per oz.)	\$7.5200
6% of \$7.52	\$0.4512
Cost of treatment	\$1.6125
Taxes and realization	0.4512
Total cost	\$2.0637
Profit on 500 gm. ore	\$5.4600

The cost of mining in the district, under favorable conditions and in the more favorable mines, on a large scale, would probably be about \$2.50 per ton, which, reduced from the profit above, would leave \$2.96 per ton as the profit on the entire operation of mining and milling ores of the grade assumed above.

The above estimate, although conservative, is based upon favorable conditions which could not be obtained at all mines, and it is probable that with a small plant and less favorable conditions the cost of treatment would, under present conditions, be about \$3.50 per ton. All costs and values used are in terms of U. S. currency. Milling costs at various plants may be of interest as showing what is being done at different places under a large range of conditions.

Name.	Place.	Cost per ton.
Dos Estrellas	El Oro, Mexico	\$1.80
El Oro Mining Co.	El Oro, Mexico	1.53
Guanajuato Con. Co.	Guanajuato	4.49
Isabella Mill	Cripple Creek, Colorado	0.87
Rand Mines average	South Africa	1.33
Ivanhoe Gold Co.	Kalgoorlie, Australia	2.20
Oroya Brownhill	Kalgoorlie, Australia	3.30
Associated Northern	Kalgoorlie, Australia	2.85
Associated	Kalgoorlie, Australia	2.76
Great Boulder	Kalgoorlie, Australia	2.66
South Kalgoorlie	Kalgoorlie, Australia	2.65
Gt. Boulder Proprietary	Kalgoorlie, Australia	2.48

The custom rates on Cripple Creek ores at Golden Cycle mill for various grades of ores are:

Class of ore.	Freight to mill.	Treatment charge.
Up to \$ 8	\$0.75	\$3.25
\$ 8 to 10	1.00	3.50
10 to 15	1.00	4.25
15 to 20	1.00	5.00
20 to 25	1.25	5.25
25 to 30	1.25	5.75

It would therefore appear that with cheap power and local milling facilities, with the large quantities of good ore available, approximately 500 gm. silver, Parral should become prosperous and her brilliant past be succeeded by a still more brilliant future.

The area of a circle is equal to the area of a triangle whose base equals the circumference and the perpendicular equals the radius.

PROTECTION OF MEXICAN INVESTORS.

Written for the MINING AND SCIENTIFIC PRESS
By F. J. H. MERRILL.

In discussing the protection of investors in mines and mining securities we are brought face to face with the fact that there are many dangers outside of errors in technical management, or misrepresentations as to ore reserves and possible or probable profits.

The large amount of American and English capital sent into Mexico, gives importance to the consideration of possible dangers which may accrue to investments in Mexican mines through ignorance of the laws relating to mining titles, their ownership and their transfers. The Mexican mining code is simple, and in many ways preferable to the corresponding laws in the United States, especially in limiting all sides of a mining claim by vertical planes. Furthermore the possibility of legal complications affecting the ownership and transfer of mining properties in Mexico is no greater than in the United States. The main dangers arise from the lack of penalties for the violation of its provisions, and from ignorance or neglect of other codes affecting the tenure and transfer of property. Dangers may also arise from incompleteness of the indexes and the lack of publicity in the records of the mining offices and the offices of public registry for transfers of real estate and encumbrances.

A mining title in Mexico is essentially real estate, except that its permanency depends on the payment to the Government of an annual rental or *impuesto* of six pesos or \$3, for each *pertenencia* or unit of 100 metres square. This rental is payable in three installments due respectively on the first day of March, July, and November. If the tax is not paid within one month of the time when it falls due, a penalty of 50% is added; if not paid during the second month 100% penalty is added; if not paid during the third month the property may at once be declared forfeited, and is then open to re-denouncement, that is, to re-location. Where the delay in payment is due to unavoidable causes, such as litigation, a petition to the treasury department, setting forth the reasons for the delinquency, may result in an extension of time for paying the tax, or a remission of part of the penalty.

The titles to mining as issued by the Government, purport to be absolute, but really depend for their safety on the accuracy of the surveys and the care with which they are tied to fixed points which may be readily identified, as well as on the fact that no prior denouncement has been made on the same ground. This is wholly the risk of the investor, for, if it happens that a denouncement be made, and through the carelessness or incompetency of a surveyor the survey be not accurately tied to fixed points, or if these points be not accurately described, a second denouncement may be laid over the first and a separate title observed, and the latter, if more carefully located with reference to the tie-points, may displace the first denouncement. Occupation may be of no importance in establishing title, on

which the original application was based has been so made that the bearings taken to points of reference are indecisive in case of a law-suit. These conditions may be better understood when it is stated that sometimes the only points of reference are mountain peaks several miles away. In such cases it is obvious that, with poorly adjusted instruments or careless reading, the exact position of the starting point of a survey may be indeterminate within two or three hundred feet.

On ground where other claims have long been established, and where a new denouncement adjoins older ones which are well monumented and have long remained in undisputed existence, the problem is simpler. But sometimes, a new denouncement is made over an old one which has laid unmonumented and forgotten by all but its owner, who has kept the taxes paid, and after some money has been spent by the owner of the later title, the proprietor of the original one arises to assert his ownership.

The Mexican mining code provides for the placing of monuments of substantial and permanent character, but there is no penalty fixed for neglect to obey this provision. Consequently instances have occurred where a careless or malicious person has taken up a claim and left it unmonumented. Subsequently a second person has innocently located another claim on virtually the same ground, only to find, after going to considerable outlay that he has been spending money on another man's property. Under such circumstances the Government has held that the original owner who left his claim unmonumented should pay all expenses of the second denouncement. This, however, might be no adequate compensation for loss of time and opportunity; moreover, the original owner might be financially irresponsible.

A further danger may arise when mining properties are located on or near the boundaries between districts. The organization of the Mexican Republic into States and Territories is somewhat similar to that in the United States; the districts of the Mexican States corresponding, in a measure, to the counties of our own country. Each county or *distrito* is a unit of administration for the various departments of the Federal Government. There is, therefore, in each district, an *Agencia de Minera* or mining agency, where all applications for mining or denouncements are received and transmitted to the *Secretaria de Fomento* at Mexico City.

The boundaries between some of the States and districts are indefinite, and though their general position is determined by reference to mountain peaks or other natural objects, these points of reference are sometimes twenty miles or more apart, and a mountain peak as a survey monument is a rather broad and vague object, so that the exact position of the line may be determined only by an expensive survey which involves selecting fixed points on the mountain tops. The upshot of this is, that in some States a mineral claim near a district boundary may be located by different persons in each of two adjacent districts, and two separate titles issued in good faith by the President of the Republic, the question

as to which title shall stand, being sometimes a matter of litigation involving a survey of the boundary. Of late, in such disputes, the Court has held that the earlier denouncement shall have precedence, but this does not indemnify the later claimant, who may have acted in good faith. As all the State boundaries are district boundaries, a mineral claim in the vicinity of one not accurately surveyed should be located with extreme caution and it may be advisable to apply to the Court to declare it legally located in a certain district.

Title having been issued on the basis of an accurate survey, and the taxes paid when due, the subject of transfer may arise. This is one of the most serious questions which complicate Mexican mining titles, because many persons undertake to make and receive transfers, without considering the provisions of the Mexican law. First is the matter of the right to convey. Under the Civil Code of Mexico, a wife has a half-interest in all property acquired by her husband during the state of matrimony except that received through inheritance or gift. Consequently, she must join in all conveyances of such property or they are illegal and void. In fact, judgment on a note given by a married man, but not signed by his wife, cannot be satisfied out of his real estate. Many a mining title in Mexico has been jeopardized by a conveyance from a married man, often an American, whose wife is not living with him, and whose existence is not known, but whose legal interest in one-half of the property still remains active. Furthermore, in Mexico, when a married woman dies, her heirs inherit her half interest in the husband's property so, it may be said, that when a man's wife dies, he loses half his fortune.

Under such conditions a widower might make an invalid transfer of a mine because a half interest in the property had passed through his deceased wife to her children. This half-interest of the wife in mining property taken up by the husband during the state of matrimony is often a disturbing element when a married man has been employed by another person or by a company to take up mining titles in the capacity of agent, but without power of attorney or specific legal authority.

Besides the legal questions which may affect the right to convey, are those which affect the right to receive a conveyance. Concerning individuals these only relate to the frontier zone of twenty leagues within which no foreigner can hold real estate without special permission granted for the specific piece of property under consideration. The right to hold real property is somewhat more difficult to obtain for foreign corporations, because they cannot do business or hold property: in other words they have no legal existence, in Mexico, until they have been protocolized. This is a process which involves placing on record with the Department of 'Exterior Relations' at Mexico City, complete copies of the articles of incorporation, by-laws and minutes of the American corporation, accompanied by translations into Spanish made by an official interpreter. These must all be certified by a Mexican Consul. A

company thus protocolized becomes in effect a Mexican corporation with all legal powers but, as the Mexican Republic levies a tax on the capital stock of corporations, in order to avoid this expense, another method is frequently resorted to. A Mexican corporation is formed with a nominal capitalization to hold the title to the property and the stock of this Mexican company is held by the American corporation.

It is unfortunately true that many American mining companies have been formed to operate in Mexico which have never put themselves in a position to legally hold property, and the stockholder's money has been obtained, so to speak, under false pretences, because the company has no legal title to the property which it claims to own and undertakes to operate.

Sometimes the Mexican property is held by an officer of the company, but frequently the person holding the title has never been appointed or authorized by the company to act as trustee of its Mexican property, and so the company has no legal control over it. Again we hear of cases where the American and Mexican companies are duly formed and the titles are held by the latter, but the stock of the Mexican company is not transferred to the American company. We also hear of instances where the American and Mexican companies are duly formed, and the stock of the latter transferred to the former, but the title to the mining property is held by some individual who made the denouncement for the company. Theoretically, it would be a simple matter to put all details of title and incorporation in the hands of two good lawyers, one in the United States and one in Mexico, but this is often neglected. While, no doubt, many companies have their business transacted in a thorough manner, many are careless.

The writer is cognizant of a mining corporation formed under the laws of one of the Middle States, and of which the officers are reputable lawyers in an Eastern city, which took up properties in Mexico under the following surprising conditions. The American company was not protocolized and no Mexican company was formed to hold titles. Certain titles were purchased from a married man whose wife did not join in his conveyance and who was subsequently employed to make other denouncements which he in turn conveyed to the company without his wife's consent. These conveyances, which were invalid, were all made directly to the American company, which had no legal existence in Mexico, and therefore could not hold property, and the company leased its supposed holdings to another American corporation, which built a mill on the property and undertook to operate it. To cap the climax of loose business methods, one of the stockholders of the original company obtained a loan on this absolutely worthless stock, from a Mexican bank which was too careless to investigate the condition of the titles and the legal status of the corporation.

As a result of extensive experience with the matters in question, I am confident that, in any future revision of the Mexican mining code, much good

might be accomplished by provisions and penalties, such as I venture to suggest. Loss of property should follow failure to comply with that section of the law relating to the erection of monuments within, say, three months. Punishment by imprisonment should be inflicted upon a surveyor who is instrumental in locating a claim on ground where he has knowledge that a prior denouncement has been made. Greater publicity is needed in the records of the local mineral agencies; more complete indexes and especially indexed district-maps showing the ranch boundaries, on which all claims shall be plotted as soon as the titles are granted, such records to be open to inspection by the public. Further, where a denouncement is made close to an unsurveyed district boundary, the mineral agent should be required to notify the central mining office in Mexico City so that comparison might be made with the records of the adjacent district and thus avoid conflict.

The points above mentioned relating to mining titles, have all been matters of dispute or litigation in the State of Sonora during the past four years.

A leaky hand-hole in the rear end of a boiler, where the plate had been allowed to leak until the head of the boiler had corroded away so that it could not be kept tight, was repaired by a correspondent of the *Engineers' Review* as follows: A steel ring $\frac{3}{8}$ in. thick and $1\frac{1}{2}$ in. wide was procured from the boiler-shop and put on. To do this the ring was bored for $\frac{1}{2}$ -in. rivets and corresponding holes were drilled in the boiler-head and countersunk on the inside, in order to bring the heads even with the plate and leave a clear place for the packing. The countersinking was done by placing the drill-chuck in a piece of $\frac{3}{8}$ -in. pipe and running it through the front hand-hole. By fitting the countersink in the chuck and the outer end of the pipe in the ratchet, one man did the turning while the other kept the countersink in the hole, and from running out of centre. When driving the rivets, a cupped piece of pipe was used to hold them in place in the same way, until they were headed. Then by the use of a gasket that did not require 'following', the job was completed satisfactorily.

Titanium has been used in small proportion in some high-speed steels, and to a considerably larger extent it has been used in the manufacture of other steels. It is reported to add greatly to the hardness, tensile strength, and elastic limit of steel, closely resembling vanadium in this respect, though Guillet seems to think its influence unimportant. Information is lacking as to whether or not titanium can be used to replace other hardening elements to any considerable extent. It is so widely distributed and is so cheap compared with the other hardening substances used in high-speed steel, that its exploitation in this direction will be watched with interest. Unlike titanium, the ores of uranium occur but rarely. Some experiments have been carried on to determine the utility of uranium as a high-speed steel alloy; but thus far it has not been shown to add any important qualities which are not obtainable by the use of cheaper elements already much used.

LAW OF MILL-SITES.

Section 2337, U. S. Revised Statutes, provides for two classes of mill-sites, as follows: (1) Where non-mineral land is used by the proprietor of a vein or lode for mining or milling purposes; and (2) where a quartz-mill or reduction-works is situated on non-mineral land and no mine is owned in connection therewith.

The statute is silent as to the manner of locating such mill-site and as to the conditions of its tenure after location. It is well established that, where the mine is abandoned, an unpatented mill-site of the first class will be held to have been also abandoned, for "there can be no mill-site (of the first class) unless there is a lode or vein to which it may attach." There would be no doubt but that the mill-site under discussion would, under the circumstances, be held to have been abandoned if it were of the first class. But since the original owner has erected a quartz-mill on it, there is good reason for holding that, by virtue of the existence of the quartz-mill, it became a mill-site of the second class, and that it is no longer essential that a mine should be owned in connection therewith. The mere abandonment of the mine would not, under such circumstances, result in the abandonment of the mill-site.

Whether a mill-site has been abandoned is a fact the determination of which is dependent upon the particular circumstances. The courts have held that lapse of time does not of itself constitute an abandonment, and is only a circumstance for the jury to consider in determining the question whether there has been an abandonment. The question is one of intent. As already intimated, the statute does not provide the manner of holding a mill-site when once located, but it has been decided that annual labor is not required to be performed on such a location. A reasonable use of the mill-site is all that is required. Just how long an unpatented mill-site might be allowed to remain idle without being forfeited would depend upon the particular circumstances of each case. If a mill-site has actually been abandoned, improvements situated thereon, of the nature of a quartz-mill, being fixtures, and, therefore, becoming a part of the realty, would revert to the government, and would become the property of any subsequent locator, and cannot be removed by the original owner of the mill-site after a valid re-location has been initiated.

The production of primary spelter in this country in 1908 amounted to 210,424 short tons. Compared with the production in 1907 this is a decrease of 39,436 tons, or 15.8%. The domestic consumption of spelter decreased from 228,509 short tons in 1907 to 215,401 tons in 1908—a loss of 5.7%; the production of spelter in the world decreased from 813,842 short tons in 1907 to 799,644 tons in 1908. In 1908 the domestic production was about 26% of the world's production; in 1907 it was about 30 per cent.

A horizontal distance is equal to the sloping distance multiplied by the cosine of the angle of the slope.

PROTECTION OF INVESTORS.

The committee appointed by the Pacific Coast section of the Mining & Metallurgical Society of America to outline the character of the information to be given to shareholders of mining companies, has recommended:

For the full protection of investors every mining company should incorporate in its annual report the following essential items of information:

1. A brief review of the past history of the property, the work accomplished and the results obtained, with tabulated statement of expenditures and receipts from the beginning, marketable products made each year, and the sums received from the sale of

ing shares entitled to participate in dividends.

In the third paragraph the words "competent authority" have been changed to "officers of the company." This is to make the persons responsible for the operations of the company also responsible for any statements as to probable life and valuation.

ALASKA-YUKON EXPOSITION.

The buildings for this important exposition at Seattle are approaching completion, and there is evidence of wide-spread interest in this Pacific Coast exhibition of natural and manufactured products. The mining exhibit promises to be unusually fine, the display including gold-saving devices of many kinds. The U. S. Geological Survey will establish a

Mines Building, Alaska-Yukon-Pacific Exposition, Seattle.

same, the annual net earnings and the disposition made of such earnings.

2. A similar review, but in more detail, of the work of the year, with statements of the assets and liabilities (these statements to show all details as to capitalization of the company; the number and classes of shares outstanding at date of the report; the respective rights of these shares; the number of shares remaining in the treasury; any options or contracts on such shares; any bonded indebtedness), receipts and disbursements, cost sheet, and other information as to work accomplished and results obtained.

3. A statement of ore reserves at the date of the report, compared with the reserves of the previous year, with an estimate, by the officers of the company, of the probable life of the mine, and a valuation of the property, accompanied by statement of the data upon which such valuation is based.

The foregoing is practically the resolution adopted by the New York section of the Society, with the following exceptions:

In the second paragraph a parenthesis is inserted to specify details of capitalization, so that an investor may be able to learn the number of outstand-

model rescue station, illustrating the application of safety devices in coal mines. Alaska will have a splendid array of gold nuggets and copper ores.

Test for titanium, according to Fenton, may be made with dihydroxymaleic acid in cold dilute aqueous solution, which gives an intense reddish brown solution. V does not give any such coloration. In concentrated solutions the reagent gives a voluminous chocolate-colored precipitate, which acts as an acid, affording bright orange-colored salts, which might be used as an indicator. The compound is destroyed or prevented from forming by HF or fluorides.

Since the conquest of the country by the Spaniards Mexico has been a great producer of silver and, more than any other nation, up to the middle of the last century had influenced the relations of this metal to the affairs of the world. Besides the great shipments of the refined metal which were made to private owners and as contributions to the Crown of Spain, the mints of Mexico coined for domestic use and for shipment to the Far East a grand total of over 3,000,000,000 oz. of silver.

Difficult Air-Cushion Problem.

It was early apparent to those familiar with the varied needs of mining that electricity would eventually play a most important part in the work. But progress was relatively slow, due to the failure of designers of electrical equipment to realize the conditions which they must meet. In the coal mining industry two types of machine have been prevalent, the so-called breast machine, with which the cutting is done by knives or chisels rigidly held on a moving chain, and the puncher machine, in which a pick is given a reciprocating motion, striking successive powerful blows against the coal. The application of the electric motor for driving the chain-machine was comparatively simple, for the rotative motion of the motor readily lent itself to driving the chain through the medium of gears.

But the problem of utilizing a motor to give reciprocating motion to the pick was far more difficult of solution. Evidently, in a percussive tool, the vibrations if transmitted direct would be destructive to the motor. While the problem has been attacked from almost every conceivable point, experience has demonstrated that in order to give sufficient flexibility the blow itself must be struck through the medium of compressed air. Hence in the development of the only successful electrically driven puncher the compressor cylinder has been retained and different means of compressing the air have been devised. In but a single case, that of the 'pneumatic' coal puncher, was the fundamental

segments, and micanite insulation. The armature is drum-wound with formed coils. It is built substantially, and the utmost care has been exercised in obtaining the greatest capacity from the space occupied.

By a novel and simple arrangement of gears the circular motion of the motor is transformed into the straight-line motion of the primary or air-compressing piston in a cylinder at the forward part of the machine. In the same cylinder is a second piston connected with the striking pick, but having no mechanical connection with the first. Under the influence of the air which is compressed by the first piston, and delivered through the open ports controlled by the same piston, the second one is alternately driven backward and forward, but is always prevented by the air-cushion from striking at either end of the stroke. As the maximum amount of power is required only when the air is being compressed during the backward stroke of the motor-driven piston, and during the control of the machine, that required by the electric motor is uniform, regardless of the character of the material in which the machine is working. The piston diameter is $6\frac{1}{4}$ in. A final pressure of about 80 lb. in the compressing cylinder has been found best for operation. At 220 volts the motor runs at three speeds, giving 170, 155, and 140 strokes per minute. The power taken never exceeds $7\frac{1}{2}$ hp., about $\frac{1}{3}$ of that required by other types of machines of equal capacity.

The operation of the machine is as follows: the pinion B on the end of the armature-shaft A, engages with the

requirement fully realized, namely, that the blow should be struck by air expanding in the same cylinder in which it is compressed. This machine, built by the Pneumatic Machine Co., Syracuse, N. Y., and illustrated herewith, comprises within the same frame the electric motor and the air cylinder. In its design and construction it displays many novel and ingenious features of interest to the electrician, the engineer, and the mechanic, even more than to the coal miner. The driving motor, which is of the ordinary series-wound four-pole type, possesses no unusual features tending to make it complicated or requiring special generators for supplying current; but is designed along standard lines with reference to the work to be done. This motor, with vertical shaft, is completely enclosed, the motor-frame and gear-case cover being made in one piece of cast-steel. By this means, strength, light weight, and simplicity are secured. Support for the upper or commutator end of the motor-shaft is furnished by a Hess-Bright radial ball-bearing. At the lower end is provided a ball thrust-bearing for taking the weight of the armature, and also a long bronze bushed bearing for taking up the lateral thrust due to the motor-drive.

On account of the necessity of employing an enclosed motor, the matter of ventilation and cooling of the various parts became important. It is accomplished in the following manner. The air to be compressed is drawn in through the armature and field windings at each forward stroke of the air-compressing piston. By this means about 28 cu. ft. of cool air per minute passes over the heated parts at a velocity of about $2\frac{1}{2}$ ft. per second. This has been found effective. It is entirely automatic, requiring no auxiliary appliances.

The insulation on the field coils and armature windings is of the highest insulating and water-resisting quality. The commutator is made of drawn bars of solid copper, mica

main driving gear C. Through the medium of the internal gear F, the crank pin E, and the crosshead H, the rotating movement of the armature is changed into the reciprocating motion of the piston rod I, and the piston J. The latter, or rear-piston, which is driven by the motor, compresses air on its backward stroke, the front piston K, with which it has no mechanical connection, follows simultaneously, because of the vacuum produced by the recession of the piston J. Air is coincidentally admitted to the front side of piston K, through the port R. On the rear side of the piston J, next to the motor, the air is compressed, and just at the end of the stroke is admitted through large by-passes to the space between the two pistons. As a result the front piston is forced forward by the entire body of compressed air, which is admitted almost instantaneously. The speed is far higher, and the resultant blow is much more powerful, than in the ordinary compressed-air coal-cutter, although the amount of air expanding behind the pneumatic system is much less. During this stroke, air is drawn into the cylinder behind the piston J, through the main inlet valve O. On its forward stroke the air in front of the driven piston K, escapes through the port R, but after the piston has passed and therefore closed the port, a sufficient amount of air remains to cushion the blow and to prevent damage to the front cylinder-head. This cushion-air may leak somewhat, and to prevent an insufficient supply, which would have the effect of producing a partial vacuum in this space and of holding the front piston on the return stroke, a small inlet valve R, is placed in the forward part of the cylinder to allow air to flow in under these conditions and before the open port is passed. After the front piston K has made its forward stroke the rear piston J follows, mechanically driven as before, and would compress the air which has just made the stroke of the front piston, which then remains between the two pistons, but for the so-called vacuum-valve

S, which allows all air between the pistons above a certain pressure to escape to the atmosphere. The placing and action of this prevent the two piston-faces coming together.

Multi-Current Feed-Water Heater.

It has been demonstrated that to attain the highest efficiency in feed-water heating the steam and the water to be heated must be kept in motion at a considerable and uniform speed, and that the changes in direction of flow shall result in counter currents of steam and water in close contact, and so directed as to compel the greatest transfer of heat possible. Heaters are ordinarily designed with little regard for the right direction and speed of flow. Area of heating surface alone does not determine the capacity of a heater. The essential thing is the proper directing of the moving currents and the speeds at which they shall flow. These conditions are perfectly met in the construction of the Blake-Knowles heater, and tests show clearly high efficiency. The interior of the shell, through which the steam

passes, is divided by longitudinal partitions, in which the water-tubes are so arranged that the steam flows the entire length of the shell, in close contact with these tubes, three times before finally passing out. The water-tubes are securely expanded into the tube-heads, one of which is a part of the main casting, while the other is bolted to a flexible diaphragm, the periphery of which is fastened to the shell flange. This takes care of the tube-expansion and makes unnecessary any troublesome stuffing-boxes for the individual tubes. These water-tubes are of small diameter, so that the heat passes quickly through the water, and six changes in direction of flow give the high water-velocity essential for the best working results. Removal of the heater-heads gives access to the interior, and the tubes are easily cleaned from the top end. These heaters are also made horizontal, and are fitted with saddles in place of feet, as in the case of the vertical type.

They are built in a great variety of sizes covering the range of modern engineering demands. Further information in regard to these heaters may be obtained from The Blake & Knowles Steam Pump Works of New York and Boston.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

MINING METHODS IN EUROPE. By Lucius W. Mayer. 8vo., pp. 169, ill., index. New York: Hill Publishing Co., 1909. Price \$2.50 net.

The elaboration of the notes taken by a technical man on his rambles constitutes a contribution which is often more striking than a formal treatise. No attempt at systematic presentation is made. Methods are described as they come to the traveler's attention. A large part of the work is devoted to coal, iron, and slate mining in Great Britain. Cave-mining is represented, but details are wanting. It would be impossible for a mine superintendent to adapt much from Mr. Mayer's account of the caving system as practised in its early home. In the account of long-wall work, however, a mass of detail and lucid description, aided by diagrams, enables the reader to appreciate the processes in principle and application. This part of the work, and the minute accounts of the flushing system of mine-filling as practised in Germany, give to the book a high importance. In these particulars it may be regarded as a most valuable presentation of data but little known in America. There are many typographic errors, and others that should have been eliminated in editing. For example, an entire chapter devoted to the famous Cleator Moor mine in Cumberland, is gravely dedicated to Creator Moor.

THE MINERS' POCKET-BOOK. By C. G. Warford-Lock. 5th Ed., entirely re-written, 8vo., limp leather, pp. 624, ill., index. London: E. & F. Spon. 1908. Price \$4.

This volume is so well known as to require little comment. It has been a handy assistant for practical men for many years, and this new edition has been brought up to date as regards mechanical improvements. For the sake of those unfamiliar with the work it may be stated that it is especially strong in the treatment of methods of transmitting power, shaft-sinking, mining methods, and hauling and hoisting.

Commercial Paragraphs.

W. R. GRANT is now with the MINE & SMELTER SUPPLY Co. at Salt Lake.

The BYRON JACKSON IRON WORKS, West Berkeley, Cal., has recently received a repeat order for two deep-well turbine pumps from the Star Paper Mills Co., Kansas City, Missouri.

The TRAYLOR ENGINEERING CO., Allentown, Pa., is distributing two new catalogues, No. H and V-1, the former on concentrating mills and machinery and the latter on furnaces and smelting accessories.

The WOOD DRILL WORKS, of Paterson, N. J., is distributing, through its New York City and Boston representatives, Harold L. Bond Co., a folder giving the detailed points in the construction of the Wood rock-drill, with the advantages in these special features.

THE C. O. BARTLETT & SNOW CO., Cleveland, Ohio, advises that the new coal handling plant which it has recently installed for the Crows Nest Past Coal Co., at Michel, B. C., was started February 1 and is giving complete satisfaction. The new equipment accomplishes with 17 men in 12 hours what formerly required 68 men for 16 hours.

L. VOGELSTEIN & Co., New York, give the following figures of German consumption of foreign copper for the month of January, 1909:

	Tons.
Imports of copper	11,788
Exports of copper	552

Consumption of copper

11,236
As compared with consumption during the same period in 1908, of 14,160 tons. Of this quantity, 11,125 tons were imported from the United States.

MINING AND METALLURGICAL PATENTS.

PLACER-MACHINE.—No. 912,766. John R. Wood, Chicago, Illinois.

No. 912,766.

No. 914,925.

In a placer machine, the combination with a suitable frame, a sluice box supported thereon, means for varying the inclination of the sluice box, and a series of riffles in said box, of perforated pipes arranged longitudinally and transversely in the sluice box above the riffles, a spraying nozzle having an expanded mouth adapted to deliver a laterally expanded jet, a hopper arranged to feed the material from above and in front of the spraying nozzle and vertically corrugated amalgamating plates suspended longitudinally above the riffles.

DUMPING-CAR.—No. 914,925. William J. Chance, Dawson, Yukon Territory, Canada.

A dumping car comprising a wheeled truck, a frame section, means pivotally connecting the frame section to the truck to permit endwise swinging movement of said section, a body, links pivotally connected to the body and to the frame section, to permit the said body to swing to opposite sides of the truck.

APPARATUS FOR CONTROLLING THE ADMISSION AND RELIEF OF PRESSURE TO TANKS AND OTHER APPLIANCES.—No. 914,497. Edward C. Moore, Philadelphia, Pennsylvania.

In apparatus for controlling and utilizing fluid pressure, the combination of an appliance to which the pressure is to be applied, a pressure pipe leading to said appliance, valve devices to control said pressure pipe to admit pressure to said appliance, means automatically controlled by the conditions in the appliance to operate said valve devices to admit pressure to the appliance, and devices controlled by the means to operate the valve devices but independent of the conditions in the appliance to control the action of said means to operate the valve devices after said means have been actuated under the control of the conditions in the

appliance to operate said valve devices to admit pressure to the appliance.

DREDGER-PUMP.—No. 914,283. Franklin H. Jackson, West Berkeley, California.

In a centrifugal dredging pump, a shell having a counterbored wall, side liners having outwardly projecting flanges at the rim, fitting the counterbored wall of the shell, said liners converging outwardly toward the centre, and having inwardly projecting annular flanges contiguous to the centre, forming balancing ring and guide tubes for the impeller, and side disks or covers exterior to said liners and bearing thereagainst.

DUMPING-BUCKET.—No. 914,753. Herbert J. Russell, Glens Falls, New York.

In a dumping bucket, a suspension device therefor, a closure for the bucket, a latch for said closure, a pulley, a link pivotally connecting the pulley to the suspension device, a connection between the pulley and the latch, and an operating cable passing over the pulley for raising and lowering the same to operate the latch.

METHOD OF OPERATING ELECTRIC FURNACES.—No. 914,346. Paul L. T. Héroult, La Paz, France.

The method of operating an electric furnace which consists in shifting the face of the charge toward or from an electrode while holding the current terminals stationary; and in maintaining the charge in a substantially vertical column with an inclined face and in passing the current from an electrode to said inclined face of the charge.

EDITORIAL.

A CORRESPONDENT at Tientsin writes to warn young mining engineers from going to China without a contract or a definite engagement, as the chances for employment are poor at the present time. The American government does not push American enterprise in the Orient like the Japanese, German, or French governments, therefore avenues for employment are not numerous. Fortunately, there is ample scope for American energy in regions under the stars and stripes; young men need not expatriate themselves so long as this continent remains incompletely explored.

PLANS for the Pacific Coast meeting of the American Institute of Mining Engineers provide for a visit to Yellowstone Park, September 25 to 30; at Spokane, October 2 to 6; Seattle, 8 to 11; Tacoma, 12, and Salt Lake City, October 15 to 19. The special train is to leave New York September 22, and return just a month later. The schedule as worked out makes it possible for those so desiring to attend the celebration in San Francisco, October 13, and the American Mining Congress at Goldfield, October 11 to 16, with little loss of time. Large preparations are being made to entertain visitors at Goldfield. Nevada has appropriated \$5000 for a special display of minerals, and numerous excursions, including one to Tonopah, are being arranged.

SKINNER'S 'Mining Manual' is a valuable compendium of information and we make use of it often; it is with surprise therefore that we find the name of a company entitled A-Bo-Kou Limited, of which the chairman is Mr. A-Bo-Kou himself, who it appears is a juggler incorporating himself for purposes of business, presumably in the Kaffir circus, a division of the London Stock Exchange. There are others. At Boston there is a clown with a quite fearful command of slang who advertises himself and his stock-jobbing operations, accompanied by financial antics worthy of A-Bo-Kou. Under the guise of a reformer he fooled many of the people for a long time and he has been known to play hocus-pocus with schemes of some merit. It is not necessary to particularize further. In mining camps the gambling den is next door to the saloon; in large cities the bucket shop is the annex of a circus wherein cruel things are done for the merriment of the crowd.

WHEN THE PINCH in silver prices came, the Mexican miners cast about for someone on whom to lay the blame. They found fault with the Government, which is most natural; the whole course of political education in America has taught us that the administration is to blame for all our financial

mishaps. We have no intention to hurl jibes at our Mexican friends; it was cruel luck, and to come down from easy prosperity to the solemn duty of working hard for a living leads inevitably to some grumbling in the earlier stages of the new adjustment. The thing that pleases us is to note how bravely they have fought out their battle, so that even in Guanajuato, which was in greater danger perhaps than most of the rejuvenated silver centres, not a single mine has closed. With silver selling at 50 cents per ounce the district is producing in actual value an amount exceeding the output in the bonanza days of long ago. The modern spirit has dominated; the production is increased in the face of falling prices, costs per ton are reduced, and the world as well as the miner gains by the process. The able engineers at Guanajuato are deserving of high commendation for their fine achievement.

DREDGING for gold is one way of becoming wealthy; it may also be a rapid method of losing money. When a person talks of 'gold ships' and tells you that placer mining is like manufacturing, it behooves you to cock your weather eye. We have been favored with a copy of the letter, pamphlet, and report inviting the public to buy the stock of the Lightfoot Dredging Company, an enterprise incorporated under the laws of Arizona by persons doing business at New York. We are told that "in every gold producing country these wonderful gold ships are producing more than 75% of the world's present yield of gold." The proportion is $2\frac{1}{2}$, not 75, per cent. This affords a scale for measuring the accuracy of the other statements submitted by the promoters of this scheme. Moreover, it is said that 64,000,000 cubic yards of gravel averaging \$1.10 per yard can be dredged for 4 cents per yard. This is one of those things that are important if true and delightful if confirmed. When we read the supposititious evidence for these alluring statements we find reason for scepticism. The M.E. who reported on the mine obtained his average of 64,000,000 yards by panning—no drill-tests or shaft-sinking is mentioned. If a single dredge, that is, an operation based on one dredge only, is working for 4 cents per yard, inclusive of all expenditures to be debited against revenue, we would like to know where it is. If the Lightfoot company is to achieve such unusual economy, an explanation should be given. It is probably true that the big dredges at Folsom, with buckets of 13-ft. capacity, have worked for a cost of even 3 cents, but that is in ground of exceptional character. Average results are more nearly exhibited by the two following examples of work done, under excellent management, at Oroville: A dredge having $3\frac{1}{2}$ -ft. buckets, digging in ordinary loose gravel and sand, had an average working cost, for six years, of 7.9 cents per cubic yard. Another dredge, provided with 5-ft. buckets, working in tight gravel and clay, showed an average cost, for four years, of 9.9 cents per cubic yard. The second dredge, if operating on the same ground as the one first cited, would operate for 5.6 cents. These figures should be pasted in the hats of would-be dredging experts.

Beam Recrudescent.

Longevity of error has been the subject of much philosophic disquisition. An equally fertile subject would be the periodic reappearance of the mining faker. Among the latter is a certain A. Mills Beam, of old notoriety, now attracting attention in central Missouri. Beam's exploits in connection with the Arkansas black-shale frauds are especially well known to readers of the technical press. By means of false assays a gold excitement was developed in southwestern Arkansas about ten years ago. To the confounding of all other assayers, Beam claimed, by virtue of superior knowledge and methods, to be able to find gold in the material. During a test, at the St. Louis Sampling and Testing Works broken crockery was cleverly substituted for his samples, yet his marvelous methods proved superior even to this obstacle. The details of the transaction were published at the time and have since been frequently re-published as Beam has, at short intervals, come to the surface in other districts. When the Kiowa-Comanche reservation was opened in Oklahoma, a mining excitement developed in the Wichita mountains. Again Beam, this time, however, not alone, for success begets imitation, was able to find gold and silver where reputable assayers found none. Here artistic finish was given to the performance by shipping a carload of the so-called ore to Denver. It was gravely "sampled and purchased" by Beam and a draft for the amount passed through the Lawton bank, to the great encouragement of stock peddlers. A careful sampling of the property by a representative of the Federal Government failed to show even a trace of gold or silver.

In the present case there is the usual story of mysterious westerners investigating an abandoned coal-shaft near New Cambria, Missouri, and of assays made at Denver. A company is formed and enters into negotiation with the 'United States Smelting & Refining Co.' for a plant; Beam representing the latter, refuses to imperil the good name of his company until convinced of the existence of sufficient ore "to assure the success of the enterprise." and is therefore employed to examine and report. Now, remembering that this is a region of Carboniferous limestones and coal measures, as innocent of eruptive rocks as the inhabitants are of mining knowledge, mark what is found. "There appears from general deduction to be a basin here almost surrounded by a coalfield; this basin is undoubtedly an eruptive section. . . . We find a large section of Feldspar assaying gold \$135.00, silver \$2.50, total \$137.50. The chances are it is from a chimney or ore chute nearby." This is in keeping with the blasphemous comment that follows, some of which is unfit for publication: "It is surprising and somewhat out of the ordinary to find gold in an old settled farming country like this. But there is a time for all things; out of the great unknown where He hides His wonders until His people are made ready to receive them and draw this treasure from the earth for the good of fellowman. Solomon, the wisest man the world ever produced well says: 'Gold is where you find it.' So

the gold being here, let the whys and wherefores go unanswered as to how it got there." Even so—especially the last. In view of Beam's record, any question as to how the gold got there might really prove embarrassing. And so the Boone Baldwin Pioneer Gold Mining Co. has been organized with 100,000 shares at \$1 per share, and profits of 36½ per cent are estimated—"as we will build a large mill." Of course no stock is being offered for sale; it is much too valuable. All this is old as the hills, even to the detail of having a 'Judge' among the directors. It ought not to deceive anyone, and yet by adroit wording and suppression of facts it has deceived one of our Eastern contemporaries, which gravely publishes a write-up of "the only gold mine in Missouri." This is the greater pity in view of the evident need of public education regarding mining matters in this area. To have a mining journal itself fail under such circumstances to discriminate between true and false is pathetic. Fortunately Mr. H. A. Buehler, the State Geologist of Missouri, has been asked to examine and report on the property. We have no doubt that he will admit a flood of light, and we also have no doubt he will be abused for doing so.

As for Beam, that mild-mannered, soft-spoken gentleman is too old an offender to warrant hopes of reform. Doubtless from time to time he will continue to trail across the stage from obscurity to obscurity like the re-incarnated Mulvaney tootling on the beer bottle at the Queens Praying at Benares.

Rights of Shareholders.

On another page we publish a letter from the manager of the Goldfield Consolidated Mines in which objection is made to certain criticisms appearing lately in these columns. These criticisms were not aimed at the gentleman who makes the rejoinder, but at the policy of the directors by whom he is employed; indeed, even they are only involved in the discussion as having afforded an example of the kind of corporate irresponsibility that is so injurious to legitimate industry, whether in mining, railways, or any other form of human enterprise. We have criticised the Goldfield Consolidated on the score of excessive capitalization and insufficiency of information given to shareholders. There be those who will say that this is none of our business, that mining journals should furnish technical information, and leave financial affairs alone. It is argued that some shareholders do not care whether they receive information or not as long as they get dividends, while others care less for dividends than for enhancement in the quoted price of the stock. One shareholder informed us that he thought 'they' were going "to do something with that stock," meaning that it would be boosted by those in control. He added that there were lots of people who would sell the stock when it went to \$2 and mortgage their homes when it was kited to \$15. To such persons speculation in mining shares is like the race-track game and mining itself only an excuse for a gamble. To them it makes little difference whether annual reports are issued in good form or are the mere simulacra of informa-

tion, whether the manager reports to the shareholders as a body or to the privileged insiders who are called directors. On discussing the matter with two shareholders of record, we were informed that they had received no news of the recent discoveries, in fact, no communication save the annual report, which, being experienced mining men, they had thrown into the waste-paper basket, as it gave them no real information concerning the condition of the mine. As one of them said, the only value of the report arose from the fact that it recorded the names of the officers of the company. We do not doubt that the Manager keeps his directors well informed and we are aware that belated information concerning the discoveries was given to the local paper at Goldfield, but how many of the 6000 shareholders see that paper, and what trust can they place in the stuff appearing in its columns? Some of the facts, in garbled form, appeared in the San Francisco papers. Thus, in a haphazard way, the stockholders may have had an inkling of developments at the mine, sooner or later, chiefly later.

This matter is worthy of discussion on a broader basis. The vagaries of individual companies are of small moment except in so far as they establish a bad example. As long as mines are run in the interest of those that control the management, as long as the minority shareholder is considered to have no rights, as long as the operation of mining is merely incidental to gambling, the industry of mining will take rank with other forms of predatory enterprise. At present the public participating in mining adventure consists largely of the clever operators, and their friends, who control the management of mines, and on the other hand, a large number of people who 'play' the stock-market 'game,' as they 'play' the slot machines, the lotteries, the race-track, and other lures for the unwary. Such people neither profit from mining nor do they profit mining. Their fate is dolorous and the people they support are the undesirables of finance. What is needed is the participation in mining of the conservative investor, of the people who buy United States Steel, of sensible speculators of the type attracted by the better kind of mining undertakings listed in London, Boston, and New York. The support of those who regard mining as a legitimate business, instead of a 'game,' will do more to advance the best interests of the industry than all the boosting of stocks. The day of the Comstock and its impudent frauds is gone; the era of clean enterprise, like that of the Lake Superior copper mines, is here. And the only way to enlist the financial support of serious people is by giving them the protection to which as shareholders and co-owners they are entitled.

Mining needs the co-operation of the men of business, not of the mere tipsters and get-rich-quick mob of simpletons; we want to see the day when a banker need not apologize for putting his money into a mining company. And it is for this that we criticise. If our criticisms are not useful, they had better not been made. The policy of this journal is simple: To be interesting by being truthful, and to tell the truth not only in an interesting but in a serviceable way.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

M. L. REQUA is at New York.
A. E. DRUCKER is at Kolar, India.
NICOL BROWN is visiting mines in Spain.
F. W. BRADLEY visited Virginia City this week.
W. SPENCER HUTCHINSON, of Boston, is in Jamaica.
J. GEORGE LEYNER of Denver was at Salt Lake recently.
C. F. NOURSE, of San Francisco, has gone to New York.
WILLIAM FRECHEVILLE has returned to London from Spain.
ROBERT A. KINZIE is on his way back to Treadwell, Alaska.

EDWARD T. MCCARTHY is inspecting the Spassky mine, in Siberia.

G. D. B. TURNER, of New York, was in Salt Lake City last week.

COURTENAY DE KALB will lecture at Stanford University next week.

C. COLCOCK JONES is examining properties in the Tintic district, Utah.

LLEWELLYN HUMPHREYS, of the Gunn-Thompson Co., was at Yerington, Nevada, last week.

B. BRITTON GOTTSBERGER has resigned as general manager for the Tennessee Copper Company.

D. J. MATHESON was in San Francisco on his way from London to Charters Towers, Queensland.

HUNTINGTON ADAMS is manager for the Cia. Minera de Natividad y Anexas S. A., of Oaxaca, Mexico.

BAINBRIDGE, SEYMOUR & Co. have been appointed consulting engineers to the Vagliano Collieries, Limited.

L. C. TRENT has opened an office at Salt Lake City, as representative of the Traylor Engineering Company.

HUNTINGDON ADAMS has been appointed manager for the Compañia Minera de Natividad y Anexas, of Oaxaca, Mexico.

WILLIAM CRUYT, manager of the Gold & Platinum Co. of Novita Viejo, Colombia, is on his way from Brussels to Colombia.

VERNON D. J. HOAR, from South Australia, and lately at Kalgoorlie, W. A., is visiting the mines of Nevada and California.

L. V. CUMMINS, formerly superintendent at Forrest Hill, has been appointed superintendent for the Parlin Mining Co., in Tuolumne county, California.

H. F. LEFFVRE has been appointed general manager for the Central American Exploration & Development Co., and is now on his way to Bluefields, Nicaragua.

J. E. SPURR has returned to New York after a two months trip of inspection of the properties owned by the Guggenheim interests in Mexico.

E. W. KEITH, western manager for the Empire Zinc Co., Denver, Colorado, was recently in Salt Lake City, on his way to the Coeur d'Alene, Idaho.

W. B. DEVEREUX, Sr., and WILLIAM G. DEVEREUX have been at Rhyolite, Nevada, inspecting the Pioneer Lease, and are now making an examination of the Melones mine, in California.

Obituary.

JAMES R. RAND died March 30, at St. Mark's hospital, Salt Lake City, of pneumonia, aged 34, and after an illness of only a few days. Mr. Rand was vice-president of the Ingersoll-Rand Drill Company, and president of the Rend-rock Powder Company, vice president of the West Quincy Mining Company, and a native of New York State. He was a graduate of Cornell, and during the Spanish war, a lieutenant of engineers. His home was Montclair, New Jersey, but he spent much of his time in New York City and at Salt Lake.

General Mining News.

ARIZONA.

GILA COUNTY.

(Special Correspondence).—Interest in the operations of the Cactus Development Co. has been heightened by the strike of ore in the shaft on the Arizona National property, under bond to the Cactus. This shaft is down over 250 ft. and has cut a low-grade silicious orebody about 75 ft. wide. The Cactus company will soon start another shaft on the Pinto creek property and will let a contract for 500 ft. W. A. Eaton, of Duluth, president of the company, and C. W. Pritchett, consulting engineer, have been at the property for several days. Operations at Miami are increasing. The ore reserves are now estimated at more than 14,000,000 tons averaging 2¾% copper. Construction work upon the 10-mile extension of the Gila Valley, Globe & Northern railroad from Globe to Miami was started on March 31, and it is expected that it will be finished in four months, perhaps in less time. On the Keystone property, under bond to the General Development Co., a shaft is being sunk, and at 138 ft. is in sulphide and carbonate ore assaying 6 to 7% copper.—At the Live Oak operations are confined to the extension of an old adit at shallow depth, in which years ago sulphide running ½ to 2% copper was opened for 500 ft. This adit has been extended over 140 ft. and is still in ore. It is the intention of the management to start sinking a shaft at an early date.—The Arizona-Colorado Copper Co., whose property is situated about three miles north of Globe, has resumed sinking. On the 800-ft. level a cross-cut has passed through 30 ft. of carbonate and sulphide of copper, averaging about 3%. Richer ore in the same vein has been followed for 75 ft.—The Superior & Globe is sinking a development shaft on the extension of the Yuma vein of the United Globe (formerly Old Dominion,) which outcrops for a length of over 3000 ft. This shaft is down about 80 ft. Daniel and Charles Chynoweth, president and secretary of the company, from Calumet, Michigan, stated that the Yuma vein will be thoroughly explored.—Ore shipments from the Superior & Boston to the El Paso smelter have continued at the rate of 50 tons per day. For some time past the ore, which comes exclusively from the Great Eastern mine, has been of better grade, the returns for February averaging 9% copper. The McGaw shaft is down 160 ft. and a raise from the 400-ft. level to meet it has advanced 65 ft. W. E. Carter, the mine superintendent, expects to have the shaft opened to the 400-ft. level early in July. The head-frame is the largest and most substantial in the district, being 65 ft. high and constructed of 16 by 16 in. timbers. The McGaw shaft is a duplicate of the Gardner shaft, having two compartments each 4½ by 5 ft., and one 5 by 7 feet.

Globe, April 1.

GRAHAM COUNTY.

The Standard Consolidated Copper Co. has awarded the contract for treating its ores to the Detroit Copper Co. at Morenci.—The ore taken from the San Jose claims, which is a silver-copper proposition, will continue to be shipped to the Douglas smelter, as formerly.

MARICOPA COUNTY.

George Sayers and Alex. Rose are the proprietors of the Delaware mine in Sayers, 10 miles east of Wickenburg. They have done about 180 ft. of development work, and already have about 100 tons of pay ore on the dump.—Three miles east of Sayers toward Castle hot springs William Kaple is sluicing a placer claim in a small way. In the same district S. Mandrich has an adit 600 ft. long, showing a 10-ft. vein which averages \$5 per ton gold.

MOHAVE COUNTY.

The Golden Star Mining Co. has been holding its annual meeting at the mines near Cerbat. There were several of the Eastern stockholders present, including C. Stiles and George Rice, of Philadelphia. A further appropriation was

passed to enable the completion of the mill, the machinery for which is now mostly on its way from the builders.—The Gold Road Mining Co. is in course of erecting a 40-stamp mill, entirely equipped with electric motors to be driven by power from Kingman.

CALIFORNIA.

MARIPOSA COUNTY.

Edward J. Mahoney has purchased a group of four mines at Hall's gulch on the Merced river above Bagby. They comprise the Golden Cube, Lucky Strike, Rattler, and the Hidden Treasure, all of which belonged to Ollie P. Whitton, of Merced.

NEVADA COUNTY.

The report of the North Star Mining Co. shows that for the year ending December 31 the production was \$1,084,212 for a total outlay of \$655,963. The average yield per ton was \$12.03 at a cost of \$5.26 for operation, \$1.29 for development, and 72c. for improvements, etc. On the lowest levels, the 4400 and 4700, ore of good size and value continues to be developed. The inclined shaft was sunk 451 ft., and is now 5400 ft. deep measured on the dip. The last 250 ft. were sunk through vein of fair size but of poor quality. The operations of 1908 have shown the most favorable results yet obtained by the company, with the largest tonnage, largest production and profit of any year in its history.—Grass Valley has been almost excited about two rich ore discoveries occurring within a few days of each other. The last was made by J. H. Bishop at the Native Son mine, near Blue Tent, when he struck a 12-in. vein that carries abundant free gold.—The senior mining students of the University of California are in Nevada City studying the field geology of the region under Prof. Andrew C. Lawson.

PLACER COUNTY.

Two new California properties have been purchased for the Begole Mines Syndicate of Boston. They are situated in Bunch canyon, six miles from Colfax. So far they have never been developed to any extent. There is a single shaft on the property, which has been sunk only 35 ft., assays from which have shown good results. Robert Gross is president of the company.

SAN BERNARDINO COUNTY.

The California Gold & Copper Co. owns nine claims to the northeast of Vonttrigger, on the Branwell and Searchlight branch of the Santa Fe railroad. There are three shafts, and about 2000 ft. of underground development, partly in sulphide ore that carries gold, silver, and copper. To treat this the company has devised an electro-chemical process by which all of these will be extracted without smelting. A mill for this purpose is now being built, and some of the machinery has arrived.

TRINITY COUNTY.

The 1600-ft. tunnel of the Trinity River Mining Co. has been completed, and now the Trinity can be turned from its bed, and leave the channel exposed. The tunnel is 7 by 9 ft., and has taken three years work to excavate.

TUOLUMNE COUNTY.

(Special Correspondence).—The United Mines Corporation has paid off all indebtedness which involved its group of mines near Tuolumne, and within a few weeks complete operations will be resumed. E. A. James, general manager, and J. Mandelbaum, one of the principal stockholders, were here during part of last week, and before their departure all debts, amounting to about \$25,000, were paid. It is said that it will require about two weeks to make necessary repairs and alterations before the resumption of operations.—News has reached here of what is supposed to be a valuable strike at the property of the Gold Ship Mining Co., which owns a large tract in the vicinity of Groveland, and through which an ancient river channel crosses. It has been found that the lava covering the channel contains gold in paying quantity, assays going as high as \$10. Whether all the lava carries gold is not known, but steps will at once be taken to determine this. One of the richest ore

bodies ever discovered in the App mine, at Quartz, was found a few days ago, on the 1300-ft. level. Its extent is not yet known, but enough of it has been exposed to see that the vein is 12 ft. wide, all good milling ore, and with two or three feet of it remarkably rich.—The Los Angeles company which recently secured control of the Hunter, War Eagle, and Hardtack mines, has confined operations to the Hunter, but will begin at the War Eagle in a few days. Power-drills will be used.—The 60-stamp mill at the Harvard mine is in operation day and night, and a full crew of men is employed.—The O'Hara mine, situated one mile north of Sonora, and which during the past twelve months yielded about \$150,000, is being unwatered and will soon be worked again by its owner, John F. O'Hara.

Tuolumne, April 6.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence.)—The Pelican mill is now running on day and night shifts, and from 200 to 225 tons of ore are being treated daily. During the last week a King screen was put in, and is said to be effecting a saving. The plant is being fed with dump matter from the Pelican mine, and it is estimated that there are 600,000 tons of material available that will net at least \$1 per ton. W. A. Hood is manager.—A 6-in. streak of smelting ore was encountered last week in the breast of the Mollie Gibson adit, situated on Saxon Mtn. The bore is now in 310 ft. and driving is to be continued to open stoping ground. Assays just made show 168 oz. silver per ton, and 14% lead. Chas. Kline is owner.—Development work has been increased this week at the Conqueror, the working force having been added to by 20 men. The main adit is to be driven forward, while stoping will be followed as formerly. The 50-ton mill is running day and night, and the concentrate is being shipped to the Argo smelter. W. S. Pryor is manager.—The Virginia City shaft will be tapped at the 500-ft. level during the present month. There only remains about 30 ft. of ground to be broken before the objective is reached, when the old workings will be drained of water. It became necessary to run the adit 1500 ft. to gain a depth of 500 ft., which is unusual in this locality.—Another strike was made last week on the Josephine, situated on Kelso Mtn. The discovery was made in the breast of the adit, a body of lead ore having been uncovered that is from 18 in. to 2 ft. wide. The first shipment made brought a settlement of \$68 per ton in silver and lead. The drift is being extended with all possible speed to permit of stoping, when the output will be increased. John Sapp of Silver Plume is manager.

Georgetown, April 2.

OURAY COUNTY.

An important strike has been made in the Nettie B. mine, on Corbett creek, 3 miles north of Ouray. Assays show 4½ oz. gold, 260 oz. silver, and some lead. The lessees of the mine who have made the strike are Martin Cassanova and Bob Kinley.

TELLER COUNTY.

The new mill at Stratton's Independence has been closed down, and the employees have been discharged without any date being set for their return. It is declared at the office of the company that the shut-down is but temporary, for the purpose of alterations to the roasting plant.—The output of the Cripple Creek mining district for the month of March totalled 60,224 tons of the gross bullion value of \$1,382,570, or an average value of \$22.95 per ton. The greater part of the tonnage was sent to the Golden Cycle plant.—Monthly measurements at the Roosevelt Deep Drainage tunnel show that the advance in the Portal heading was 340 ft., giving a total of 5587 ft. The average for 3 months is 295 ft. per month.

IDAHO.

James F. McCarthy, manager of the Hecla mine, Harry L. Day, manager of the Hercules, W. Clayton Miller, general manager for the Federal Mining & Smelting Co., and Myron Folsom, counsel for the Bunker Hill & Sullivan mine

were the representatives of the Coeur d'Alene district at a conference at Salt Lake City last week, to protest against the reduction of the tariff on lead ore and pig lead. The delegates of these four Idaho companies, representing one-third of the lead production of the United States, prepared a memorial to be sent to the Western senators and representatives.

SHOSHONE COUNTY.

(Special Correspondence).—An official report of progress at the mine has been mailed to the stockholders of the Reindeer Mining Co. This report states that the adit is in 2450 ft. and that only 425 ft. are required to intersect the vein. Progress is being made at the rate of 177 ft. per month.—John H. Nordquist has been commissioned to purchase equipment for the Idora mine on Sunset peak. It is intended to equip the property with all necessary machinery for development, and later on a concentrator will probably be erected. All the outstanding debts of the company have now been paid, and the treasury is in excellent shape. A branch of the Idaho Northern railroad will be built into the Sunset region during the coming summer, and when this has been done shipments will be commenced.—It is reported that the property of the Horst Powell Mining Co. on the Little North Fork has been bonded to Finch & Campbell, of Spokane, for \$40,000. Upward of 7½ ft. of good copper is exposed in the mine.—Fire broke out in the compressor house of the Anchor mine at Burke last Wednesday and about \$700 of damage was done to the machinery and building. None of the men were injured. It is believed that the fire was caused by defective insulation.—It is reported that arrangements have been completed for the erection of a concentrating plant at the property of the Tamarack & Chesapeake Mining Co. The showing in the mine is said to be excellent.

Wallace, April 1.

MICHIGAN.

Recent developments at the Lake mine are encouraging. The north drift on the second level has again passed into rich copper ground after driving through 80 ft. of barren trap. The lode at this point is exceptionally rich in copper, with the mineral more evenly distributed than is the case in the south laterals. On the third level no drifting has yet been done, but a cross-cut has disclosed good ore about 90 ft. from the shaft. It had previously been indicated by diamond-drill holes.—Developments at the Tecumseh mine of the La Salle Co. continue without material change in the underground conditions. The mine is opened horizontally for a distance of approximately 1000 ft. at several levels, mostly in stamp-rock of fair grade. No sinking has been done for nine months, as the full capacity of the hoist has been reached.—At a meeting of the Arcadian Copper Co. the directors gave the New Baltic Exploration Co. an option on the company's interest in section 16. Arcadian will get 5000 shares of stock in the New Baltic Co., when organized, and \$40,000 cash.—The Mass Consolidated Copper Co. has extended the seventeenth level cross-cut in shaft A to the lode recently disclosed in diamond-drill operations, and drifting on the lode is now in progress. It shows a width of 12 ft., and is said to be of exceptionally good grade.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—Resumption of activity is promised in several old tracts in the district which once were rich and well worked, but have since lain idle and become filled with water. At present the Lone Elm tract lying along Turkey creek is being unwatered with centrifugal pumps. Fourteen companies have taken sub-leases and will work the old shallow deposits.—The Mohler-Smith Co., operating at Carl Junction, is again adding to the capacity of its plant. This company recently installed a steam-shovel in the open pit which took the place of 38 shovelers. A 250-ton mill has been on the lease for some time, and a 150-ton plant is in course of construction. A contract is now to be placed for a third mill. The company is operating a deposit in an old bed of Spring river.

which is both extensive and rich.—The 300-ton mill of the Cameron Mining Co. in the Sarcosie camp is completed and has started operations with two 8-hr. shifts. A flume is being built to the mill from the old Sangamo shaft to furnish mill water, as the shaft of the Cameron could not supply enough.—The J. C. Barr mill of 300 tons capacity in the new sheet-ore zone south of Webb City has been completed, but the initial run has not yet been made. It is being watched with interest, as it is the pioneer in this new field. Several other companies are sinking shafts in the vicinity, but no production is reported up to now.—The 400-ton Meadville plant which was built last year in the Duenweg camp has now been removed to the Rhea Lead & Zinc Co.'s lease north of Webb City and is ready for work. Three levels are being worked, all in the sheet formation.—The Little Persimmon, in the Carthage camp, made its first shipment of zinc-blende last week. This lease has been under development intermittently for a number of years, and has several shafts, but has been operated very little. The deposit is in soft ground and requires heavy timbering; water is also troublesome in the rainy season.—The strike which was made a few weeks ago in the bed of Spring river near Carthage by the Empire Electric Co. while enlarging the dam at Forest mill, continues to increase in richness as work progresses. It is the first strike in that vicinity, and for that reason is important. The Empire Electric Co. will not develop the ore, as it is not a mining concern. The ore is zinc-blende of high grade. Joplin, April 1.

MONTANA.

There has been a gain of \$108,378 in the amount of gold received at the United States assay office in Helena from

Montana.

the various counties in Montana during the quarter ending March 31, 1909, compared with the quarter ending March 31, 1908. This gain is attributed to the fact that numerous new mines, both placer and quartz, have been discovered and put in operation during the last 12 months. The principal producing counties are Fergus, Chouteau, and Madison.

FERGUS COUNTY.

D. J. Burr, a mining engineer, who recently made an examination of the Abbey Cyanide Gold Mining & Milling Co.'s property on the eastern slope of the North Moccasin mountains, near Kendall, says in his report that the orebody is of great size, and is suitable for milling and cyaniding. The shaft has been sunk 200 ft. from the bottom of which a cross-cut has been run 256 ft. Drifts and other cross-cuts show the orebody to be 34 ft. wide and to assay an average of \$7 gold per ton.

SILVER BOW COUNTY.

Drifting on the vein on the 1400 ft. level of the Davis

Daly has opened a large body of copper glance. The results are so encouraging that a cross-cut will be at once started on the 1200-ft. level to prove the size of the orebody.—The East Butte Copper Co. has got control of the large amount of water that impeded development work on the 900-ft. level for several weeks.—Owing to the low metal prices no ore is being mined or shipped from the Lexington mine at present. All work is confined to development.

NEVADA.

CHURCHILL COUNTY.

The sinking of the shaft of the Nevada Hills Co., at Fairview, has been discontinued while the drift on the 400-ft. level is being advanced for development. As soon as enough ore has been sufficiently proved, W. H. Webber, the manager, will test for the best method of ore treatment, with the idea of milling his own ore.

ESMERALDA COUNTY.

The Goldfield Consolidated Mines Co., during the month of March, produced 19,351 tons of ore, of which 19,010 were milled in the Consolidated and Combination mills, and 341 were shipped to smelters. The estimated net value recovered from this tonnage is \$1,074,020, while the total cost of production amounts only to \$124,020. The output of the other mines of Goldfield were valued at only \$260,000 for the same period.—Cross-cutting from the bottom of the old Engineers' shaft, at a depth of 500 ft., is being vigorously advanced to reach a point under the bottom of the main shaft, when a 2-compartment raise will be put up to connect with the shaft. On the fourth level, the new work on the Engineers' vein continues in rich ore, and is still of shipping grade, although the width has increased with the advance of the drift.—C. D. Wilkinson, superintendent of the Daisy, says that his mine is in good condition. Much of the ore is worth \$150 per ton, and there is abundance of it. The station at the 500-ft. level is about completed, and as soon as the shaft is down to 700 ft. the output is to be greatly increased.—The Mammoth Mining & Development Co. owns the French mine situated at Gold Mountain, 40 miles south of Goldfield. A contract for the erection of a 30-ton mill, comprising stamps and Huntington mills, is now being drawn up by Albert Crosby, of Goldfield. The directors of the company are P. and L. Julien, and J. W. Crane, of Goldfield.

NYE COUNTY.

The weekly report of the Tonopah Mining Co. shows that the Mizpah was sunk 13 ft. to the 1309-ft. point. The flow of water has slightly increased, but is only 60 gal. per minute. A total of 408 ft. of new ground was broken in the various workings, 269 in Mizpah ground, 39 in Red Plume, and 100 in Silver Top. This is exclusive of work done in the stopes. An average of 96 of the 100 stamps were dropping continuously in the mill, crushing 3075 tons, worth \$22.50 per ton.—All operations in the Stone Cabin shaft of the Jim Butler have been suspended, and it is believed that work will now be done through the Wandering Boy shaft, the repairs to which have just been completed.—Nine hundred and thirty-nine tons were treated at the Montana mill, with an extraction of 85.5%. This low extraction was due to an excess of slime that caused trouble with the settlers, and necessitated the addition of a new one. The underground work shows an advance of 219 ft. in the week. Five days were occupied at the Belmont in repairing timbers in the shaft, at the point where it is intersected by the Mizpah fault. This temporary cessation of ore shipments did not interfere with the operation of the mill at Millers, where a thousand tons of ore were kept in reserve.—From the MacNamara 350 tons were shipped, mostly to the Western Ore Purchasing Co. In future all ore will be sent to the Belmont mill. The shaft sinking advanced 28 ft., giving a total depth of 680 ft.—The total output of the Tonopah mines for the week was 5249 tons, with an estimated value of \$131,250.

STOREY COUNTY.

(Special Correspondence) The weekly output of the Comstock mines has fallen off considerably of late owing

to the caving of portions of the Sutro tunnel and the repair work going forward at several points. The Ophir and Consolidated Virginia are practically the only mines at present producing, and the yield has dropped to below \$10,000 per week. The damage occasioned by the recent fire is being rapidly repaired.—At the Ophir, ore is being taken out from the 2100, 2200, and 2300-ft. levels. A west cross-cut is under way on the 2000-ft. level.—Some development work is under way at the 1950 and 2150-ft. levels of the Consolidated Virginia and ore is coming from the latter point.—At the Crown Point some fair-grade ore is coming from the surface workings. It is being treated at the Yellow Jacket mill.—A blower has been installed on the 2000-ft. level of the Mexican, to furnish air for the 2200 ft., where considerable work is going on.—The water is being steadily lowered in the Ward shaft and no difficulty is being experienced in handling the flow. Several repairs have been made and a sinking pump is being placed in condition for service.—Repair work is being vigorously pushed in the Comstock tunnel, but owing to the shifting nature of the ground and other obstacles, progress is slow.—The Potosi, Chollar, Savage, and Hale & Norcross have suspended temporarily.—The east cross-cut from the south drift of the Confidence-Challenge-Imperial shaft at the 70-ft. level is progressing slowly in fair-grade ore.—At the Yellow Jacket a raise from the south drift on the 1200-ft. level is in milling ore, while the east cross-cut is also in fair grade rock. The ventilation has been much improved by the installation of air-pipes.

Virginia City, April 3.

WHITE PINE COUNTY.

The Granite district is in the Egan range, 30 miles north of Ely. The best developed property there is that of the Blaine Mining Co.; the principal interested parties therein are D. S. Dickinson, W. B. Graham, James Reilly, and D. Clark, all of Ely. The vein has a porphyry foot-wall and a quartzite hanging wall, dips 31° to the east, and has a width of 3 to 4 ft. There are over 2000 ft. of development, consisting of a 550-ft. incline on the vein, a 925-ft. cross-cut from the side-hill to the vein at the foot of the incline, and drifts on the vein at the 50, 150, 225, and 300-ft. stations, aggregating 400 ft. All the levels will be operated through the cross-cut adit. The ore is a gold-bearing quartz, about 60% of the gold being free-milling and the remainder associated with iron sulphide. Tests of samples indicate a general value of \$20 per ton. The company contemplates erecting a 10-stamp mill this year. The Blaine is 6 miles west of Shepherd's station on the Nevada Northern railroad.

SOUTH DAKOTA.

LAWRENCE COUNTY.

Diamond-drill prospecting is progressing on the property of the Elliptic Mining Co., northwest of Deadwood. The work was commenced at the bottom of a 600-ft. shaft, where a station was cut for the drilling apparatus. Driving had previously been started on that level, but without success in reaching ore-shoots. The diamond-drill, however, has struck a free-milling orebody about 600 ft. from the bottom of the shaft, the dimensions of which are not yet definitely determined. The company has started another hole from a point on the surface about 1000 ft. southeast of the shaft.

UTAH.

JUAB COUNTY.

The Tintic smelting plant, now under the superintendency of George G. Vivian, has four lead furnaces of 250 tons daily capacity each, three of which are in operation; and one 250-ton copper furnace, also in blast. The latter is soon to be doubled in capacity. The lead furnaces produce a bullion containing about 99% lead, with 240 oz. silver, and 1 oz. gold per ton of bullion. The copper furnace produces a 40% matte, carrying 250 oz. silver and 2.5 oz. gold per ton of matte. The plant having no converters, the copper matte is shipped to the U. S. Mining & Smelting Co. Besides the tonnage of ore being received from the Jesse Knight mines of the Tintic district, the company has con-

tracts with others in the district calling for 500 tons of ore per day. Among the contract shippers is the Grand Central, at Mammoth, which is getting ready to resume operations after having been closed down for several months.

The May Day, managed and controlled by John Dern, is shipping 500 tons of ore and 100 tons of concentrate per month. The first-grade ore averages 50% lead, and 50 oz. silver per ton; the second grade will run 24% lead and 20 oz. silver. This ore all carries from \$5 to \$20 gold per ton. The Uncle Sam, under the same management, has been extensively developed during the winter and will soon be in position to make regular shipments. C. C. Griggs is superintendent of both properties.

SUMMIT COUNTY.

The New York mine, under the superintendency of M. J. McGill, has a new shaft, now at a depth of 750 ft., and the sinking in progress will continue till 1000 ft. shall be reached, after which lateral development will be carried on.—The Grasselli Chemical Co. has in operation a dry concentrating plant for zinc-lead ores, situated near the ore sampler in Park City. The mill, which is equipped with Sutton, Steele & Steele dry concentrators, is in charge of E. Nesbitt, who states that the plant is treating 75 tons per day of zinc, lead, and iron middling from the Daly-Judge concentrator, making a clean separation of the various minerals.

CANADA.

BRITISH COLUMBIA.

J. E. McAllister had posted a notice to the effect that the British Columbia Copper Co. would close both mines and smelter on April 1. Shortly after a committee of smelter men proposed that if the company would agree to continue operations the committee would endeavor to induce all employees to accept a 10% reduction in wages. We do not know if the wage reduction was brought about, but anyhow the manager has reversed his decision, and operations will continue as heretofore.

COSTA RICA.

Phenomenally rich ore is being developed on the Tres Hermanos vein of the Abangarez Gold Fields Co. It is a free-milling ore from which a 5-stamp battery, in a run of eight days, gave a yield by amalgamation alone of \$18,000 in bullion.

MEXICO.

CHIHUAHUA.

The Batopilas Mining Co. has been in bonanza ore for the past three months. Two hundred and eight-seven bars of silver, worth about \$300,000, arrived in Chihuahua representing the February output. For January the output was 205 bars, and in December it was 199 bars. The mines of this company have produced \$21,712,353 up to December 31, 1908. It is stated on good authority that the management is now planning to build a cyanide plant.

OAXACA.

The dam for the water-power of the Socorro Mining & Milling Co., in the Nochistlan district has been completed. The machinery for the reduction plant is now all on the ground and the mill will be speedily completed. The work is in charge of J. E. McCreary, who has had the contract for most of the mills erected in this district.—The new milling plant of the Carmen mine, in the Sierra Juarez, is giving excellent results. The 1650-pound Nissen stamps are doing more work than had been expected. Callow pulp thickeners, vanners, and Wifley tables are used in concentrating, and the total gold extraction is 93 per cent.

PERU.

The receipts of copper from Peru during the month of February were 6,284,520 lb., which is almost double that of the previous highest month. Nearly all this is from the Cerro de Pasco Copper Co., owned and controlled by the Haggin-Hearst interests. For 8 months of the fiscal year ending with February, there has been received in this country from Cerro de Pasco mine a total of 18,545,095 lb., comparing with 14,899,272 lb. in the same period of 1908.

Special Correspondence.

WASHINGTON.

Proposed Legislature—Department of Mines.—Mining Experiment Stations.—Land Courts.—Leasing Public Lands.

Although the session of Congress just begun was called by President Taft for the purpose of revising the tariff, and it is not likely that there will be much legislation outside of this and census bills, a flood of new bills has been introduced in both Senate and House. A number of them relate to mining, among them being several for either a bureau or a department of mines. Senator Heyburn, of Idaho, has re-introduced his familiar bill calling for a Department of Mines to be under a Commissioner of Mines. Representative Douglas, of Ohio, who took such a leading part in the previous Congress on this subject, has submitted a bill calling for a bureau of mines, with a Commissioner at its head. This is practically the same as the bill Senator Dick attempted to get through the Senate on the closing day of last session. Senator Gamble and Representative Martin, of South Dakota, have introduced slightly different bills providing for the establishment of mining experiment stations, to aid in the development of the mineral resources of the United States. Mr. Martin's bill is similar except that it places the bureau under the Department of Commerce and Labor instead of the Treasury.

Mr. Austin has presented a bill providing that "no common carrier of interstate commerce shall transport or accept for transportation the products of any factory or mine in which convicts are employed or permitted to work, which products are offered to said interstate carrier by the firm, person, or corporation owning or operating said factory or mine for transportation into any other State or Territory than the one in which the factory is situated." Senator Heyburn has introduced a number of bills relating to the public lands, the most important being one to establish land courts and an appellate land court of the United States. These courts, to be known as District Land courts, according to the bill, would be established in each of the States and Territories that contain more than 2,500,000 acres belonging to the United States and subject to entry or sale. In other States where there is less public land, the nearest District court would have jurisdiction. The District courts are to have jurisdiction to hear and determine all contests involving the right to occupancy, entry, and patent of the lands of the United States. Section 2326 of the Revised Statutes regarding patenting of mining claims is extensively amended. Another bill introduced by Mr. Heyburn provides that the title to mining claims heretofore located by persons holding commissions as United States deputy mineral surveyors shall not be held invalid by reason of the fact that such locations were made by deputy mineral surveyors during their incumbency in office in violation of Section 452 of the Revised Statutes of the United States.

Senator La Follette has presented a bill reserving from entry and sale the mineral rights to coal and other minerals mined for fuel, oil, gas, or asphalt upon the public lands of the United States and providing for the entry of the surface of these lands and also for the leasing of the mineral rights in such lands. Prospecting upon any of the public lands shall be done only by such persons as have received a prospector's license, which will be issued without charge.

A second bill was introduced by Mr. La Follette providing for the valuation of the segregated coal and asphalt lands in the Choctaw and Chickasaw nations in the State of Oklahoma, and for the sale of the surface and the disposition of the mineral rights therein. The bill provides that these lands shall be appraised by a board of three to be appointed by the Secretary of the Interior Department, one of them to be a member of the Choctaw and Chickasaw nations, one who shall have a practical knowledge in the valuation of mineral rights, and one with knowledge of

the land values in Oklahoma. In making the appraisal, the bill provides that the lands shall be classified in areas of 40-acre tracts. It is further provided that the Secretary of the Interior may sell the surface of these lands by sealed bids, at not less than the appraised value and no one person may obtain more than 160 acres of agricultural land, nor more than 640 acres of grazing land. The proceeds of the sale of these lands and the leasing of the mineral rights shall be distributed to the enrolled members of the Choctaw and Chickasaw tribes or nations, and the money to be distributed per capita. The mineral rights are to be rented under conditions similar to those in the first bill.

MEXICO.

Mexican Northwestern Railroad.—Northern Electric Power Co.—Greene-Gold-Silver.—Santa Eulalia Shipments.

A recent change that is of direct interest to the mining industry of Chihuahua is the purchase by F. S. Pearson and his Canadian associates of the Chihuahua & Pacific railroad and the timber and railroad interests of W. C. Greene. For the proper handling of these acquisitions Pearson has organized the Mexican Northwestern Railway Co. of Canada, with a capital of \$40,000,000. Of these

Part of Chihuahua.

securities \$3,000,000 has been placed in the hands of the Bank of Scotland for sale. The plan seems to be to push the railroads to a connection and thence to the west coast of Sonora. The organizers have had the wisdom to get upon the directorate Enrique C. Creel, Governor of the State of Chihuahua, José Y. Limantour, Finance Minister of Mexico, and E. N. Brown, president of the National Railways of Mexico, and should be free from difficulties with the Federal, State, or railway interests of the Republic.

Canadian capital is also in control of the Mexican Northern Electric Power Co., which is examining the merits of several water-power concessions on the Conchos river in the State of Chihuahua. One of these, known as the Paul Ginther concession, is about 18 miles above the town of Santa Rosalía, and at which point it is claimed 24,000 hp. may be developed. The other is about 20 miles farther up the river, at a point called La Jolla, where it is calculated 16,000 hp. may be obtained. The plan is to furnish power to the mining camps of Parral, Santa Barbara, Naica, Santa Eulalia, and other places. The waste water would be used for irrigation. Another strong company is figuring on a power scheme of like character on the San Pedro river near Rosales, Chihuahua.

Various rumors are afloat regarding the future of the Greene-Gold-Silver company holdings in the Ocampo district of Chihuahua. Both English and New York people are supposed to be looking at the properties. The Conchos mines have reverted to the firm of Corrigan & Mc

Kinney, which is preparing to resume operations. At the Pinos Altos mines, near by, controlled by the Barnesdales of Pittsburg, preparations are being made for a resumption of operations. The new mill will be completed, two 300-kw. generators are being installed for the transmission of power from the river to the mines and mill, and a motor will probably handle the ores over a surface tram from the mine to the mill. At the Palmarejo mines of the Palmarejo & Mexico Gold Fields, Ltd., near Chínipas, matters are still at a standstill, though some changes either in the construction or the location of the mill will undoubtedly be effected this year and work resumed. The Durango Mines Co. is constructing a 50-ton cyanide plant near Chínipas.

In Santa Eulalia, just outside of Chihuahua, the Santa Eulalia Exploration Co. has resumed operations after a several months' shut-down, and is sending out a better grade of ore to the Chihuahua plant of the A. S. & R. Co. The San Toy Mining Co. is also now shipping to the Chihuahua plant from its immense bodies of lead-silver ore in the Juarez and Galeana claims, and which a number of competent mining men have estimated to be in excess of 10,000,000 tons. The Chihuahua and Potosí mining companies continue shipments of about 300 tons per day in addition to the zinc shipments from the latter company's property. The Potosí M. Co., encouraged by the excellent results obtained by the Calera M. Co., which is controlled by the same interests, in the dry separation of the zinc-blende and galena, is contemplating the installation of a Sutton-Steele concentrating plant. The Madero family continues development at Cuchillo Parado, as does the Chihuahua Copper M. Co. at Chorreros, and some copper is being shipped from San Sóstenes, but were it not for the zinc shipments from Coyame and Picachos things would be quiet on this eastern branch of the K. C., M. & O. railroad.

LONDON.

Borax Consolidated.—Ducktown Copper.—Shan States Tin. — Discoveries in Dolcoath.—Kolar District, India —Nundydroog.—El Oro Developments.—Mineral Production of Great Britain.

Two mining companies operating in America have just been raising additional working capital in London, namely the Borax Consolidated and the Ducktown Sulphur Copper & Iron Co., both of which are exceedingly prosperous companies. The Ducktown company requires funds for the establishment of its new sulphuric acid works, and for this purpose 48,779 shares are being issued at 25 shillings per share. This company has been working since 1891 at Ducktown, Tennessee, and during the last 14 years the ordinary shares have received an average of 18% per annum. Some time ago the law against the emission of sulphurous fumes rendered it desirable to adopt some method of preventing their escape. The annex erected is the ordinary chamber-plant, such as is used at Swansea for saving the sulphur given off in roasting copper ores. The management estimates that the first section will be ready for operation immediately, and the rest of the plant in September. The company is in a favorable position for the sale of sulphuric acid, owing to the nearness of phosphate deposits and to the local demand for fertilizers, and it has entered into a long contract with Charles S. Bryan for the sale of its product at a satisfactory margin of profit. The other company, Borax Consolidated, has been paying since its formation in 1898, dividends averaging £263,000 a year on a share capital of £2,300,000, and it is now issuing £150,000 new capital for various extensions and improvements. This company, however, never publishes any details, so I am unable to give any information of technological interest in connection with it. The new issues by this company and by the Ducktown company have both been fully guaranteed.

Subscriptions are invited by the Southern Shan States Syndicate. This is the outgrowth of a small syndicate financed by W. B. Dick, who has extensive interests in all kinds of oils. The Shan States are in eastern Burma, ad-

joining China and Siam, and the territory exploited by this syndicate covers many thousand square miles, yielding all kinds of vegetable and mineral products. The alluvial tin attracted special attention and Euan Smith, who has had considerable experience in Malay tin mining, was sent to investigate. He has issued a detailed report showing the presence of large quantities of gravel running 3 pounds of black tin per cubic yard, and of tin ore outcrops over a wide area. The tin lodes appear to be fairly rich, and they also contain a good deal of wolfram. At the present time, in spite of magnetic separation, wolfram is not a particularly desirable constituent of tin ore, both because the separation is incomplete and because the demand for wolfram is slight.

The Ooregum mine in the Kolar district of India has now been working for 21 years. It has had two or three periods of depression, notably 10 years ago and 3 years ago, and it is now recovering from the last. In fact, the output for 1908 was a record, being gold to the amount of £329,317. The total production since the commencement of operations has been £4,866,656, of which £1,595,124 has been distributed as dividends. The average content of the ore at this mine has not been quite so great as at the Mysore or at the Champion Reef in their best days. For instance, the output during 1908 was obtained from 121,886 tons of ore, which is equivalent to about 14 dwt. per ton, and this is an appreciable increase over the last two or three years. The year's profit was £149,998, or £55,543 more than in 1907, and £93,173 was distributed as dividends. The amount of ore reserves on December 31 was greater than ever before, being 154,281 tons, and the ore developed at depth is of higher value than the average of the mine. Consequently the outlook is most encouraging.

Writing of the Mysore mine, I mentioned that at some of the other mines in the Kolar district they were not experiencing the best of luck. One of the misfortunes afflicting the field has been a serious fire at Nundydroog. This fire broke out on January 21 last, on the 1900-ft. level at Kennedy's shaft. For some time it baffled all attempts to cope with it. The only resource available was to allow the water to fill up. By February 17 the fire was extinguished, and pumping was started on the 19th. By March 3 the water was lowered to the 2300-ft. level, and the mill was re-started on the 8th. So far, Henry Richards, the manager, has not been able to ascertain the extent of the damage done. Just as the fire occurred the directors were discussing the amount of the final dividend for 1908, and naturally it was found necessary to pay less than would otherwise have been done, in order to provide funds for repairs. During 1908 the total dividends were £87,258, equal to just over 30% on the share capital. As is done at Mysore, so likewise at Nundydroog, all costs are charged against revenue instead of a portion being met out of new capital. With the exception of the fire episode, Nundydroog has been doing well recently. The reserves of ore have increased and now stand at about 1½ years supply. At and below the 2450-ft. level a wide and valuable orebody has been found, that promises well. During 1908 the tonnage crushed was 87,000 tons, yielding 74,851 oz. of bar-gold in the mill, and 6038 oz. by cyanide, the total output being valued at £303,807. The extraction was 1 dwt. higher than during the previous year. Since the mine started, in 1882, the total output has had a value of £3,319,518, of which £1,427,335 has been distributed as dividends.

Following up his report on the Mexico Mines of El Oro, mentioned by me March 20, R. T. Bayliss has issued a report on the El Oro mine, in which he gives his general impressions of the present state and future outlook of this property. He refers to the hopeful way in which the mine is developing in depth, and mentions that at one point at the 1000-ft. level the ore is running 24s. per ton, which is much higher than the average content of the mine. Mention is also made of the presence of sulphides in the lower part of the mine, but sufficient information has not yet been gained to enable a judgment to be made relating to the nature of the occurrence. In order to facilitate operations in depth,

new means of ventilating have had to be considered, and Mr. Bayliss has advised the sinking of a new shaft to a depth of 1500 ft. It is intended to continue work simultaneously from the surface and from the 486, 786, and 1000-ft. levels, so that the length of time occupied in its construction and equipment will be greatly shortened, and should not exceed 18 months. The mine also appears to have more ore reserves in the upper levels than was at first expected, and there are signs that the so-called barren zone on the 786-ft. level will prove to be of greater value than was originally estimated. Altogether, the mine and mill are in excellent condition.

The British Government issues early information relating to the output of minerals in the United Kingdom. The figures are not final, but are sufficiently close to make them of considerable value to those who want to know as early as possible how things are going. The report issued this week

Mortar-Blocks of the Mexico Mill, El Oro.

deals with the output of minerals from mines during 1908, but not from quarries, the facts in relation to which are not yet ready. The totals for coal, iron, copper, lead, and tin now published may be taken as covering the complete output, but seeing that quite half the iron-ore produced in England comes from open-cut surface workings, and is included in quarries, the figures for the total output are not complete in this case. The output of coal during 1908 was 261,506,379 tons, a decrease of over six millions compared with 1907. Similar temporary set-backs to the upward tendency in the output of the coal have been experienced in 1901, 1893, and 1886. The output of coal for 1908 is just double what it was in 1875. Increases in output are shown in the cases of tin ore, arsenic, and bauxite, but on the other hand the output of galena, blende, copper ore, wolfram, and manganese show decreases. The output of tin concentrate increased from 6079 to 6956 tons. Uranium, which is attracting attention just now, has exactly the same figure for 1908 as for 1907, namely, 71 tons of ore, the whole of which presumably came from the Grampound Road mine, in Cornwall. The fall in the blende output from 20,082 tons in 1907 to 15,189 in 1908 is apparently accounted for by the failure of the Flintshire mines. In this connection it is interesting to note that arrangements have been made for introducing large amounts of new capital to reduce the water-level in the network of mines and tunnels in the

Halkyn district of Flint, so that in the near future this part of the country may once more become an important producer of lead and zinc ores.

TORONTO, CANADA.

Cobalt Dividends.—Temiskaming.—Nipissing Statement.—Montreal River District.—Fraudulent Promotion.—Dominion Steel and Coal Companies Compromise.

The dividends paid by the Cobalt companies during the first three months of the present year amount to \$1,425,457, or about one half the total dividends paid during the whole of last year, which amounted to \$2,849,885. This is exclusive of profits of close corporations such as the Drummond and O'Brien. Dividends have recently been declared by the Nipissing and La Rose, the former being 3% for the quarter, with an additional bonus of 2%, while the La Rose somewhat disappointed expectations by only adding a 1% bonus to its quarterly dividend of 3%. Temiskaming, which was lately subjected to a bear raid, and depressed on account of large amounts of stock being thrown on the market by operators wanting money for Gowganda investments, has recovered itself, owing to favorable reports from the mine, where recently some good discoveries have been made. The latest of these is a 10-in. vein, rich in silver, found in the drift into the Gans lot at the 250-ft. level. The Beaver is another mine the stock of which has been badly depreciated of late. Development has been assiduously pushed, in the hope of picking up some of the rich Temiskaming veins, but so far without results, and the finances of the company were exhausted. At the annual shareholders' meeting on March 27 the situation was explained by the management, and authority was given the directors to increase the capital stock from \$1,500,000 to \$2,000,000, the new issue to be put on the market at not less than 10% of its par value. The financial statement of the Nipissing shows cash, bullion, ore *en route* to the smelters, and ore at mine, to the value of \$1,009,000. The ore ready for stoping is valued at \$700,000 more than on January 20. A strike was made this week on the Peterson Lake leasehold of the Little Nipissing, a good pay-shoot being found at the 150-ft. level on a vein on which considerable driving had been done. It is about 10 in. wide, containing calcite and native silver.

There has been a good deal of activity shown lately in the installation of mining plants in the mines of the Montreal River district. At the Moose Horn a complete 3-drill compressor-plant is being put in. At the Otisse-Currie a 9-drill compressor, with boilers, etc., has been installed. The Gavin-Hamilton has a 6-drill compressor and 65-hp. boiler, and four air-drills on the ground. The shaft on this property is down 57 ft., and driving has begun. The Big Six is putting in a plant comprising two 40-hp. boilers, one 4-drill compressor, and 4 drills.

Another fraudulent mining promoter is being prosecuted. William Joel of Toronto organized the Gowganda Silver Premier Co., capitalized at \$500,000, with men of straw as directors, securing for low figures 8 Gowganda claims, on none of which had silver been found. He attempted to dispose of the stock by means of circulars, making statements as to rich discoveries made on the properties. He was arrested before he had time to secure many victims, and is now on bail awaiting trial.

The Minister of Mines has introduced a measure in the Provincial Legislature to amend the law respecting mine accidents, based on a report by Mine Inspector Corkhill. Greater safeguards are provided in connection with the use of explosives, miners being prohibited from drilling at the bottom of old drill-holes, where unexploded charges often remain. It is provided that the Inspector of Mines must be present at all inquests on mining fatalities, to bring out the essential facts. Cross-heads are required to be constructed on such a plan as to insure the bucket stopping as soon as the cross-head sticks in the shaft. Penalties for the violation of mining regulations are increased, and imprisonment is provided where neglect is deliberate.

The fear entertained that the interruption of communi-

cations with Gowganda by the breaking up of the winter roads might be attended with famine, is declared to be unfounded. For some time supplies have been steadily taken in, and the requirements of the camp for months ahead are fully anticipated. J. M. Laing, president of the recently organized Gowganda Board of Trade, publishes a statement to the effect that no danger need be feared. There are 1050 tons of supplies in the hands of merchants. Six hundred teams are engaged in transporting goods to the camp from Charlton, and 200 are similarly employed on the winter road from Sellwood. The government of Ontario has appropriated \$50,000 to construct a permanent wagon road to Gowganda from Charlton. The project of a railway from Sellwood to Port Arthur, which would serve the Gowganda district as well as a rich unsettled agricultural region, is likely to take practical shape, the government having offered a grant of 2,000,000 acres of land as an inducement to the Canadian Northern railway to build the road, which must be commenced within a year and completed before the end of 1913.

The long-continued litigation between the Dominion Iron & Steel Co. and the Dominion Coal Co. is at length being amicably settled. The Dominion Coal Co. has paid over \$2,750,000 on account of the damages for which the courts declared it liable. The old contract for the supply is recognized as still in force, and the Steel company is to furnish a detailed statement of its claims for losses and to allow the Coal company to examine its books. When this has been done the parties are to endeavor to arrive at a settlement, before the assessment of damages by the referee as ordered by the courts.

BUTTE, MONTANA.

March Output. — Streams Pollution. — Pittsmont.

Operation in the Butte mines during March aggregated about 29 days of actual mining, and the production for the month is estimated at 28,077,510 lb., the various companies contributing to the totals as follows:

Companies.	Ore, tons.	Copper, lb.
Boston & Montana	102,950	7,618,300
Anaconda	108,750	6,851,250
Butte & Boston	18,850	1,187,550
Washoe	17,400	1,061,400
Parrot	12,325	714,850
Trenton	12,960	740,080
North Butte	40,890	3,761,880
Butte Coalition	38,425	3,074,000
Original	27,550	2,093,800
Pittsburg & Montana	8,700	626,400
Miscellaneous	4,350	348,000
Totals	392,950	28,077,510

Judge Hunt, in the United States Court, has given another important decision in favor of the smelting and mining companies. Hugh Magone, a rancher, in a suit against the Anaconda, Montana Ore Purchasing, Colusa-Parrot, Parrot, Colorado, and Butte & Boston companies, demanded \$20,000 as damages and an injunction, claiming the tailing polluted the streams and irrigating ditches and damaged his land in the Deer Lodge valley. Judge Hunt found that the actual damage did not exceed \$1726, and that the Anaconda company, owner of the Washoe smelter, did not contribute to the damage. The findings of the Court practically dispose of the injunction question, though Judge Hunt did not directly pass on that. By passing control of the Pittsmont Copper Co. to financial interests in Boston, that company will be provided with funds. The company has been paying about \$20,000 per month interest on bonds. Even at its present limited earning capacity the company pays that interest, all its operating expenses, and furthermore places something in the treasury each month. By diverting the \$20,000 interest to the treasury and doubling the output of the mines and smelter, which can easily be done, a good treasury and dividend-fund can be accumulated.

VICTORIA, BRITISH COLUMBIA.

Crows Nest Pass Coal Co.—Reciprocity in Coal.—Canadian Zinc.—Le Roy Mine.—New Stamp Mill.

At the recent annual general meeting of the Crow's Nest Pass Coal Co., G. G. S. Lindsey, Robert Jaffray, Sir Henry Pellatt, and E. R. Wood, all directors for a number of years, declined re-election, following the intimation by W. P. Clough, representative of the Northern Securities Co., that the American interests, which hold about 60% of the stock, desired to have the affairs of the company administered in the future in St. Paul. The Canadian directors refused to become part of what would be equivalent to a dummy board. The new board consists of W. P. Clough, Jay P. Graves, and five Canadians, one of the last, Elias Rogers, being president of the company.

The production of coal in 1908 was 981,645 tons, as compared with 981,939 tons in 1907, and 806,901 tons in 1906. Of the output 262,558 tons was made into coke in 1908, 231,368 in 1907, and 213,295 in 1906. The aggregate output since the company commenced coal-mining in 1898 is 6,217,399 tons of coal. The net earnings in 1908 were \$240,226, as compared with \$382,986 in 1907, and \$351,791 in 1906. The aggregate of net earnings for nine years, 1900 to 1908, is \$2,820,453, of which \$2,384,652 has been distributed to the shareholders in dividends. Only one dividend was paid in 1908, amounting to \$185,825, as compared with \$355,179 in 1907, and \$350,000 in 1906. No dividend was paid for the second half of 1908, owing chiefly to losses totaling \$106,712 from the fire which destroyed the town of Fernie last year. To the same cause, together with trade depression and the increased cost of mining, was attributed the material decrease in net earnings of the year. During the year several years' accumulation of premiums on stock sold, amounting to \$2,141,250, was paid as a bonus dividend at the rate of 66 $\frac{2}{3}$ % on the capital stock of the company to shareholders subscribing for new shares equal in amount to the dividend. By this the issued and paid up capital was increased to \$6,212,666.

The company has withdrawn from the Western Coal Operators' Association and has agreed with representatives of its miners on all important points in the new scale to go into effect April 1. Ten mines are operated. Only two of these are at present shipping, but others will shortly also produce coal. The total output for April is expected to be 4000 tons daily. It is intended to make it 6000 tons by next October and 8000 tons three or four months later. The erection of 1000 additional coke ovens at Fernie will be commenced this year. The company employs about 2000 men, and has an assured market for all the coal and coke it can produce. The output for the current year to March 26 was 185,160 tons. Adding about 8400 tons for the remaining three days the mines were worked, a total of 193,500 tons for the quarter is obtained.

The proposed removal of the duty on coal imported into the United States, has not moved coal mine operators in British Columbia and Alberta to any action favoring reciprocity, despite the fact that the establishment of free trade in coal between the two countries would bring about a substantial increase in Canadian production. On the other hand, coal mine owners in the neighboring State of Washington are very much opposed to the reduction. At present the duty on coal imported into the United States is 67c. per ton, while the Canadian duty is 53c. The Washington operators are at serious disadvantage even with the existing duty. The chief advantage of British Columbia coal is that of superior quality. Furthermore, Oriental labor is used to some extent at Vancouver island coal mines, about one-fourth of the employees being Japanese and Chinese, and the average wages paid to these is less than to men working in the Washington mines, which do not employ any Orientals. Under existing conditions British Columbia coal mines ship a large proportion of their product to the United States. The figures for 1908 are not yet available, but in 1907 nearly 30% of their gross output, or, after deduction of coal used in making coke, etc., about 40% of the net output went to this market. There is an

abundant supply of bituminous coal of excellent quality, both on the coast and in the interior of British Columbia, and there are good transportation facilities. The latest available figures of production show that British Columbia's gross output of coal in 1908 was 2,109,000 long tons, that of Alberta 2,046,308 tons, and of Saskatchewan, for the fiscal year ending February 29, 1908, 189,428 tons. The estimated production of the coal mines of the State of Washington in 1908 was about 3,000,000 short tons, of Oregon 25,000 tons, and of California and Alaska together 55,000 tons. It is probable the development of the coal resources of British Columbia and Alberta will be much more extensive in the early future than of the Western United States. As bearing upon Canada's probable attitude toward reciprocity, it may be mentioned that Nova Scotia coal mine owners are strongly opposed to the removal of the existing duty, claiming that they will lose their hold on the Canadian market as far west as Montreal. One result would be that they would find their main market in the New England States. As Ontario and Manitoba get their main coal supplies from the States, the removal of the duty would benefit consumers in those provinces.

At the annual meeting of the Canada Zinc Co., held at Nelson on March 30, last year's officers and directors were re-elected. The company late last year commenced at its works at Nelson the separation and reduction of lead-zinc ores in an electric furnace. The work is being re-organized and extended. Re-timbering of the Le Roi No. 2 Co.'s main shaft at Rossland has been completed to the 500-ft. level.

GOLDFIELD, NEVADA.

Consolidated Output.—*Florence Goldfield Production.* — *Hornsilver District.* — *Silver-Lead Ore at Hawthorne.*

Prospects of an extra dividend from the Goldfield Consolidated Mines Co. at the time of the next quarterly distribution of profits, 90 days hence, have been rendered a practical certainty by recent developments in the company's mines and the unexpectedly heavy bullion production from its two mills. In an official statement issued by the secretary of the company it is set forth that during the month of March the company produced 19,351 tons of ore of which 19,010 tons were milled in the Consolidated and Combination mills and 341 tons shipped to the smelters. Local mills are not designed to treat the very rich gold ores, the greater saving from which, effected by the smelting process, more than offsets the cost of transportation. It is stated officially that the net value recovered from the March output is \$1,074,020, estimated for the reason that some of the bullion is still in transit to the mints and some of the ore in transit to the smelters for which definite returns have not been received, but the estimate is declared to be conservative. The total cost of production, including all expenses of mining, milling, transportation, and office, was \$124,020, leaving a net profit of \$950,000 as a result of the month's operations. The 341 tons of ore sent to smelters represents that which has been broken from the high-grade streak in the new Combination ore-shoot, which runs from \$800 to \$1500 per ton and contains seams carrying as high as 200 oz. gold. This rich streak, which is from four to six feet wide, is a red-brown oxidized ore running through the centre of the great vein of gray sulphide, the whole mass being 40 ft. wide and yielding an average throughout of \$190 per ton. At the present rate of bullion production the Consolidated company is earning sufficient to pay ten, instead of four, dividends annually of 20¢ per share. Min-

ing men generally are greatly pleased over the acquisition by H. C. Frick and Charles Hayden of the interests in the company formerly held by Senator George S. Nixon.

A conservative estimate of the bullion output for the Goldfield district during March places the figure at \$1,300,000, including the Florence Goldfield with \$98,000, Combination Fraction \$85,000, Daisy \$35,000, other producers being led by the C. O. D. Consolidated and the Consolidated Red Top lease. The Daisy is making daily shipments of ore averaging around \$150 per ton, has a fine showing of high-grade ore on three levels, and the manager, C. D. Wilkinson, is cross-cutting for the main vein at the 500-ft. level while the double-compartment shaft is being sunk to the 700-ft. point. The importance of the strike made some time since on the Gold Bar claim of the C. O. D. Consolidated has been established by means of a raise that has been made from the 300 to the 200-ft. level, in ore containing seams of high grade. This ore shows free gold and tellurides, as well as copper. The shaft is now being sunk from the 300-ft. level and within a few days the work of exploring the ground from the 600-ft. level of the adjoining Nevada Gold Ore Mines Co. will begin.

In view of the relatively small amount of development work performed by the Florence Goldfield Co. and the fact

The Beginning of the Combination Mine, 1903.

that the new mill has been employed exclusively in the treatment of low-grade ore, chiefly from old dumps near the company shaft, the production of nearly \$100,000 in March is conceded to be most creditable, and when the main shaft is connected with the lease workings, making available the better grades of ore, it is expected that the company will be able to make a production of \$2,000,000 annually. The March product consisted of 4000 tons averaging \$20 per ton, treated in the mill, besides 23 tons of high-grade, worth \$800 per ton, which was shipped to the smelters. The rich ore came from a new strike made recently in running a connecting lateral from the company workings to those of the old Little-Florence lease in which a foot of extremely rich ore was cut, accompanied by about two feet of medium-grade stuff. This ore is now being stoped. Another rich ore-shoot has just been opened at the 500-ft. level of the old Engineers' ground. The Florence mill is working satisfactorily. With the installation of another tube-mill and additional amalgamating plates the entire equipment of 40 stamps will be brought into commission and a treatment of nearly 200 tons daily assured.

A splendid extraction of ore, both in point of quality and tonnage, is being made from the Combination Fraction mine and the managers confidently predict a million-dollar yield for the year. Nearly 100 tons daily of ore averaging around \$50 per ton is being treated at the Nevada Goldfield

mill, which the Fraction company has under lease, and beside a large tonnage of excellent mill ore the property has exposed high grade in veins that are extensions of those in the Mohawk. Beside the ore being treated locally, the Fraction has been sending out shipments of high-grade to the smelters. It is believed that the new Combination vein will be encountered on its dip in the Fraction ground at a depth of 500 or 600 ft. and the management is now considering the installation of a drill to prospect the territory at great depth. A large tonnage of good mill-ore, together with some of the richer rock, is in sight in the workings of the Little-Florence company, whose lease covers the southern portion of the Combination Fraction.

A production of approximately \$30,000 monthly is being maintained by the Consolidated Red Top lease, operating on the Red Top, and another \$20,000 dividend will probably be announced at the meeting of the directors in a few days. This company has opened a large deposit of oxidized ore at the 300-ft. level. The Red Top Mining & Leasing Co.'s shaft, on the adjoining Bull Dog Fraction, is nearing the 400-ft. mark and should encounter the Red Top vein near the 500-ft. level.

Rich ore is being stoped in a raise in the Stoneham Moore-Griffiths lease on the Combination No. 1 and 2 claims, the shipping ore having been encountered in a strong vein at a depth of nearly 500 ft. The double-compartment shaft of the Grizzly Bear Co. on the Jumbo group of the Consolidated is now more than 350 ft. deep and is being sunk rapidly by the manager, Bruce Jones, for the 800-ft. level, near which it is expected that the great Mohawk vein will be penetrated. The strongest ore-shoots of the Mohawk, including that of the famous Hayes-Monnette lease, dip directly toward this shaft and the company will still have a year's time in which to operate after that depth is reached.

Lessees on the territory of the Goldfield Merger Mines Co., the Codd lease, and the Kansas City Velvet lease, are taking rich ore from within 100 ft. of the surface on the St. Ives and Velvet veins and will penetrate these veins at depth. The Combined Mining & Leasing Co. is running a cross-cut to the junction of these veins, at which point good ore is expected. The Fairview-Cherokee lease on the Atlanta, the most important on that property, is equipped for extensive mining and has begun to drift on a great quartz lode that intersects the main Jumbo vein on this ground.

The Hornsilver district, 30 miles south of Goldfield, is making a regular production of ore from the Great Western mine, the product being shipped to the reduction works at Millers after being hauled 15 miles to the railroad at Cuprite. As greater depth is attained in this mine the ore is changing from silver to gold contents. On the Orlean group 8 ft. of shipping ore has been exposed, while a good tonnage has been opened in the Frances Lime Point lease which has made several small shipments to Goldfield. The Broken Hills mine at Helena is making a heavy production of high-grade ore from its three shafts and from several surface cuts from which the rock is sacked directly for shipment. The company is building a 50-ton mill and has exposed a big tonnage of excellent mill-ore in addition to the high-grade. In the Whitmore lease a body of rich ore has been opened and two shipments have been made.

Hawthorne is attracting attention on account of the rich silver lead ores being produced by the Lucky Boy and Alamo mines. The Hubbard lease on the latter has been making a production approaching \$20,000 daily and employing nearly 200 horses in hauling the product to the railroad. Many Goldfield operators have secured claims or leases. Mitchell & Fairfield have recently paid \$35,000 in cash for a lease on ground joining that already owned, and have shipped three hoists into the district. C. C. Hyllested, of this place, has secured a bond and lease on the Hardscrabble group, adjacent to the Alamo, and claims to have shipping ore at the surface. There is great activity all along this mountain range, south of Walker lake. A Chicago company is developing what is said to be

a copper property and a fine showing of ore has been made on the property of the Forrest Mining Co., whose property is not far from Dutch creek.

KALGOORLIE, WESTERN AUSTRALIA.

Gold Output.—Water Supply.—Placers.

The corrected figures of gold production in this State for 1908 were as under: 1908 output, \$34,950,000 against \$36,000,000 in 1907; 1908 dividends, \$7,400,000 against \$8,600,000 in 1907. During the period, the Perth Mint dealt with gold valued at \$27,400,000. Coined gold exported totaled \$23,000,000. Uncolned gold exported totaled \$9,450,000. The January yield was \$2,800,000, of which the Mint received \$2,050,000.

Coolgardie is now a dead district, a number of small free-milling mines only keeping the place alive. Several large low-grade lodes are known, but these are merely pottering with 10-stamp batteries. From time to time attempts have been made to work by sluicing and dredging the auriferous gravels that cover a large area around the mines on the east side of town, but so far without success. As high as \$1 per yard has been caught, but the expense of water, uneven bottom, etc., ate up any possible profit. In 1908 Coolgardie produced gold valued at \$850,000, against \$1,290,000 in 1907.

What has been written about the gravels at Coolgardie applies also to Kalgoorlie. Every attempt to work them by water has failed, yet dryblowers have turned over the same stuff repeatedly, and apparently make a living by it. Just out of the town of Kalgoorlie there are many million yards of gravel of an average depth of say 4 ft. resting on what is known here as a cement bottom. It would be almost impossible to form an estimate of its value, although trials have given 50c. per yard.

The maintenance of the main of the Goldfield's water supply is a heavy expense now on account of internal and external corrosion. During the period 21,200,000,000 gal. ran to waste, and at present 4,140,000,000 are in the reservoir.

January outputs from the leading mines were:

Name.	Tonnage.	Yield.	Profit.	Dividend.
Associated	11,007	\$113,000	\$33,000

Sons of Gwalia South....	1,905	22,000	3,500	30,000

*Crushed in same mill. †Loss (\$13,000 dividend duty).

†Cassel plants working on dumps. Oroya-Brownhill treated 20,443 tons of old residue by Cassel process for a return of 80c. per ton, costs being 60c., leaving 20c. profit, which is rather small.

From time to time, in various outlying districts, the Mines Department of Western Australia has erected 10-stamp mills, to crush the ores from prospects. Generally a sand treatment plant is installed, and now it is proposed to erect a few Cassel plants. These batteries have been of immense benefit to parties of men working small prospects. At the same time the battery managers, and of course the Department, came in for a great deal of abuse from those crushing. Sometimes they are dissatisfied with the treatment, or the yield, or the milling charges; though the latter are now very low. In 1908, the State mills dealt with

Golden Horseshoe announces its ore-reserves at December 31, 1908, as 1,065,409 tons at \$12.20 per ton.

In the annual report of the Goldfield's Water Supply, the following data are published:

	Gallons.
Consumption during year.....	837,296,000
Daily average	2,294,000
Mines' Supplies	397,944,000
Domestic and railways, etc.....	440,352,000
Total revenue	\$860,000
Operating expenses	\$374,000
Interest, supplementary capital. 52,000	
Sinking fund, supplementary capital	32,000
Interest, main capital.....	457,000
Sinking fund, main capital.....	400,000
	1,315,000
Deficiency	\$455,000

JOHANNESBURG, TRANSVAAL.

Chamber of Mines on Labor. — Low Costs and Ore Reserves. — Gold Yield.—Stope-Drill Competition. — Natal Resources.

Two great speeches are delivered every year by leaders of the mining industry; these are regarded as the most important pronouncements—being authoritative, comprehensive, and always carefully prepared—upon the progress of affairs and the prospects for the future. One of these is the Chairman's speech at the meeting of the Rand Mines, Ltd., and the other is the valedictory address of the President of the Chamber of Mines. Lionel Phillips made admirable use of the latter opportunity for addressing the Rand's 'financial constituents' on February 26, and being more fortunate than his recent predecessors, he was able to discuss the lessons of a wholly prosperous and progressive year. Nearly every point calling for notice seemed to provide cause for satisfaction. The troubled question of unskilled labor—the jarring note in so many past presidential addresses—was discussed straightforwardly in a brief history of recruiting operations since the war. As it was possible to record an increase of 33,227 native employees during the past year, the subject can give rise to no immediate anxiety. It is common knowledge that the renewed attempts to employ white men on unskilled work underground have not proved economically successful. At the same time, Mr. Phillips acknowledged the duties of the mines to the community in regard to the relief of distress among the unemployed. Upward of 3000 unskilled whites were taken on during the 8 months ended December 31, 1908. One direct advantage to the mines resulting from their employment has been the availability of a standing force of men, from which the good workers can be speedily picked to fill openings in the high branches as soon as they occur.

The reduction of working costs was discussed in its broadest and most attractive aspect. Analyzing the position of 67 representative mines, Mr. Phillips found that the fall of 2s. 4d. per ton in working costs allowed the inclusion of an additional 5,400,000 tons (an addition of 9%) in the ore reserves. He also pointed to the relation between costs and yields per ton. As the former are decreased so are the latter brought down by the utilization of formerly unprofitable rock. The influence of this has often been taken to indicate an impoverishment in depth, of which—below the surface zone of enrichment—there is no evidence. The yield per ton has fallen because of the reduced selection in underground schemes of exploitation. Mr. Phillips stated: "I do not think we have anything to show that the conglomerate beds at three or four thousand feet in vertical depth are any less productive than they were at one or two thousand feet." This declaration expresses no cursory view, but can be based on a careful examination of detailed figures collected from all parts of the Rand.

Mr. Phillips anticipates that the tonnage of the ore milled this year will exceed the 1908 total by about $3\frac{1}{4}$ or $3\frac{1}{2}$ mil-

lion tons. Applying this to the Transvaal totals, we may deduce the following:

1908.....	18,755,000 tons at 31.5s. = £29,957,000
1909.....	22,000,000 tons at 29.5s. = £32,450,000
or 1909.....	22,000,000 tons at 30.0s. = £33,000,000

The President of the Chamber of Mines did not commit himself to the probable yield per ton, but the two estimates given appear to allow ample for the reduction coincident with a further fall in working costs.

It would be easy to attach too much importance to the early results of the Stope-Drill Competition, the elimination trials of which are now proceeding at the University College, but enough has nevertheless been done to prove conclusively that the past year has been well employed by manufacturers. Some rapid drilling has been done by the Westphalia, Flottmann, and Climax Imperial drills. The New Century also made a good showing, but this drill is used without supports and seems to put so great a strain upon the strength and endurance of its operator that it is unlikely to meet with favor in working practice. Four drills of promise—the Chersen, Waugh, Konomax, and Murphy—have not yet been tried. Bearing this in mind, brief reference may be made to the best performances chronicled to date.

The Flottmann took part in the competition of a year ago, but its design has been changed. It is of the hammer type, fed by hand-screw, with a $2\frac{1}{2}$ -in. diam. cylinder and $2\frac{3}{4}$ -in. stroke, and weighs 87 lb. With a consumption of 193 cu. ft. air per foot drilled, it averaged in two tests 4 in. per minute during actual running time and 2.18 in. during total time. The Westphalia—a 'dark-horse' arriving from Germany, and of which little was known in Johannesburg—is an automatic-feed hammer-drill, weighing only 65 lb., with a cylinder diameter and stroke of $2\frac{3}{8}$ in. It is high in air consumption, two tests showing 224 and 299 cu. ft. per foot drilled. The Westphalia's two tests gave 4.996 and 3.421 in. per min. while drilling, or 2.675 and 1.944 in. through the tests. Corresponding figures for the 'Climax Imperial' were, for two tests, 3.842 and 3.198 in. per min. on drilling time and 2.416 and 1.910 in. on total time, with air consumption at 209.8 and 261.5 cu. ft. per foot drilled. This machine, also of the hammer type, has a 1-in. cylinder and $4\frac{3}{4}$ -in. cylinder stroke. Hollow steel is used. It only falls below the 100-lb. maximum weight by $2\frac{1}{2}$ lb. Feeding is performed of ordinary hand-rotation. The great improvement effected in these hammer-drills may be judged from a comparison of the above figures with the record of the Gorden drill (not competing today) at the trials of a year ago. The mean results then shown were as follows: Depth drilled per minute: total time (1) 1.11 in.; (2) 1.8 in.; actual drilling time (1) 1.6 in.; (2) 2.15 in. The elimination trials now in progress will disqualify several drills for the full tests to be undertaken later.

In spite of an active policy of State aid to prospectors and bonuses to pioneer producers, Natal mining has been developing very slowly. The colony's coal deposits have long been exploited and now produce upward of $1\frac{1}{2}$ million tons of high-class bituminous coal per annum, principally for railroad and ocean-steaming purposes. A wide range of other mineral resources are found, however, and these have only been attacked spasmodically. The syndicates and companies formed to prospect the gold, copper, tin, graphite, asbestos, and mica occurrences rarely seem to possess sufficient strength to carry operations to a successful issue. To what extent natural conditions are at fault, it is generally difficult to determine. The Natal Government has therefore done a wise thing in securing the services of F. H. Hatch to report on the mineral resources of the country. Dr. Hatch was similarly employed as mining specialist in 1901 by the Government of India. His acquaintance with South Africa dates back for about 12 years, during which time he has contributed abundantly to geological and mining literature on local questions. A nine month's term of investigation in Natal is suggested, and, if he is provided with ample assistance, his report at the end of this time should cover all known mineral occurrences of importance.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A ton of silver will occupy a cube $17\frac{1}{4}$ inches each way, while a $14\frac{1}{4}$ inch cube is the size of a ton of pure gold. This latter would be worth \$602,861.

Tincture of larkspur, or a fluid extract, diluted with alcohol or Florida water, is a good wash for protection against the insects that infest Indians and Eskimo.

Silver amalgam may be made readily by electrolysis, using a solution of potassium cyanide as the electrolyte, a bath of mercury as the cathode, and silver bar as the anode.

An owner of a quartz claim by virtue of valid location can prevent trespass thereon. Prospecting for gold-gravel on such validly located quartz-claim would of course constitute trespass, against which the ordinary remedy of the law would apply.

Fuel and supplies for mines in the Rocky Mountains are hauled during summer for the winter campaign. In Alaska the hauling of supplies is done during the winter, when the ground is hard; thus preparations for summer work are made while the sledding is good.

Graphite prepared and ready for market is worth about one cent per pound on either the Atlantic or Pacific Coast. The deposits in Alaska are expected to dominate the graphite market of the world. It is a remarkably pure crystalline variety, existing in immense deposits, unmixed with gangue.

Gross royalty would be a payment at a fixed rate per ton of ore produced, or on a sliding scale dependent upon gross assay value. Net royalty would be a payment at a fixed rate per unit of metal paid for by the ore-buyer, smelter, or refiner. The terms have no hard and fast meanings, but depend materially upon the provisions of the contract.

Bronze is not adapted for bearing purposes because it is an alloy consisting of a hard eutectic in which the free grains of softer metal are embedded. The ideal condition for an anti-friction metal is precisely the reverse of this, namely, a soft eutectic in which the embedded grains are harder than the matrix. For the above reason bronze bearings are liable to run hot.

Copper is found in so many different kinds of rocks that it cannot be said to have any limitations in regard to rock-association. In a general way it is true that the more basic rocks usually contain the most copper, and that concentration of that metal into veins is most likely to occur in the vicinity of such rocks, of which the gabbros, pyroxenites, and many andesites are good examples.

Tamping of dynamite charges with clay and with sand was recently tested in South Africa by a Government Commission to ascertain what advantages, if any, might result in securing more perfect combus-

tion of the explosive, so as to yield less of the poisonous carbon monoxide. It was also desired to see whether clay tamping would develop more energy from the explosive. The report states that the expected improvements were not found.

Bornite, or 'horseflesh' copper ore, is usually a secondary mineral, resulting from the reduction of solutions of copper sulphate by iron pyrite, or the copper-iron pyrite (chalcopyrite). The existence of bornite as a primary copper mineral is doubtful. The depth to which it may occur in the earth depends on the depth to which waters leaching the upper oxidizing portion of a vein may penetrate. It will not extend to a great depth below permanent groundwater. Bornite has been found deeper than 2500 ft. below the surface. It is a question of local conditions entirely.

Ochre, which is a highly aluminous admixture of various ferric hydrates, is worth from \$15 to \$25 per ton, ground and bolted, delivered at tide-water. The lighter yellows and reds are preferred to the deeper tints. Freedom from grit is one of the important points. To a certain extent this is removable by grinding and floating off, in the same manner as washing clays. After drying and pulverizing the pigment must be sifted through bolting cloth to prepare it for market. Sulphur and lime cause deterioration, and hence are objectionable. Mica is also undesirable.

Electric copper smelting has been done on a large experimental scale in France, under the direction of M. Vattier. The process is one of simple direct concentration of the copper out of the ore by fusion, ores from Chile averaging 7% copper having yielded a matte of 45% at a cost of \$15 per ton of copper produced. The slags are said to have been quite clean, but that of course depends to a considerable extent upon the type of slag produced. The making of easily fluxing mixtures can not be ignored. The process is said to offer great possibilities, and will soon be tried on a working scale in Chile.

Tantalum, which is in demand for making certain grades of high-speed self-hardening steel, is obtained chiefly from the minerals tantalite and samarskite. The former is found as opaque, lustrous, iridescent, black crystals, which yield a dark-red to black streak on porcelain. The amount of tantalic oxide in the mineral varies within wide limits, the minimum being 3% and the maximum 65. Samarskite is generally massive, though sometimes found in flat embedded grains. Its lustre is vitreous to resinous, and the color velvet-black, yielding a dark, reddish brown streak. Both minerals occur in granitic rocks, having a similar habit to tin ore (cassiterite), with which they are often associated. The surest test for tantalum is to fuse in a platinum spoon with potassium bisulphate, and dissolve in dilute hydrochloric acid, when a yellow solution will result, while a white precipitate is thrown down; addition of metallic zinc to the solution produces a blue color, which disappears on dilution with water.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Goldfield Consolidated.

The Editor:

Sir—My attention has been drawn to an editorial in your issue of March 27, 1909, wherein you refer to the published accounts of the discovery of a new orebody in the Combination No. 1 ground of The Goldfield Consolidated Mines Co., and particularly to the following sentence: "It is surprising that the information should be given weeks after the event, at the close of a period during which bear tips have been circulated."

Under ordinary circumstances I should consider it unnecessary and undesirable to enter into argument with the editor of a mining journal, on mining subjects, especially with a gentleman whose eminence in mining discussion is as pronounced as your own; for mining engineers are undoubtedly entitled to their own notions on mining subjects, and the public is at liberty, and doubtless capable, of estimating the relative value of their opinions. But in the present instance your article transcends the scope of opinion to which a mining engineer, by reason of his perspicacity, is entitled, and contains an imputation of dishonorable procedure not only in connection with my administration of the affairs of the company, but of the attitude of its directorate toward the public, calling for elucidation and correction.

You will please take note of the fact that it is my custom, as general manager of this company, to supply its board of directors monthly statements of operation, and of the further fact that it is the practice of the directors, at the commencement of each year, to furnish stockholders and the public an annual report likewise showing the operations of the company. In pursuance of this policy, on December 23, 1908, reporting operations for the month of November, 1908, I indulged in the following language: "Combination. * * * On the 4th level good ore has recently been uncovered between the Combination and the January workings, and north of the drift connecting these workings. This portion of the Combination ground has never been developed, and present indications point to the possibility that continuous ore may be traced from the Combination to the January. There are no workings between the point where this ore was found and the surface; neither is this territory undercut in any workings below. We will proceed at once to cross-cut both above and below for this orebody."

On January 22, 1909, reporting for the month of December, 1908, I indulged in the following reference:

"Combination. Company development work on the Combination consisted of 676 ft. Development work has been extended in the vicinity of the point on the 4th level where rich ore was reported last

month. A drift shows ore 6 ft. or more wide averaging about \$100 per ton for a length of 60 ft., after which values became low. The continuation of this drift was later turned to the north, and high-grade ore was again encountered in the face. This strengthens our belief that continuous good ore will be opened up for a considerable distance in this heretofore unexplored portion of the property. This same ore-shoot has been found on the 5th level, and is being opened up. Also a cross-cut has just been started on the second level to cut the same orebody above."

On February 17, 1909, reporting for the month of January, 1909, I indulged in the following language:

"Combination. * * * On the 4th level stoping has been commenced on the new rich orebody north of the old workings, and high values shown by development work hold out well. This orebody has been recently cut on the 5th level, and is proving as rich as on the level above. We are also driving on the 2nd and 6th levels for this same orebody, and indications are very promising at both points. The stopes from the 2nd to the 5th levels, between the central Combination workings and the Riley, have been producing ore of better grade than formerly."

Now, will you please particularly note that in my annual report, which was mailed to stockholders in the latter part of January, 1909, and also given to the public, appears the following language, on page 22: "Very recently rich ore has been discovered on the 230 level north and west of the older workings. A drift on this vein shows an orebody 6 ft. in width, and already exposed 60 ft. in length, which averages higher than \$100 per ton. Developments are not yet sufficient to determine the full size of this orebody, but it appears that this portion of the property, and the large area lying between it and the Mohawk workings, in which good ore was formerly unknown, may be very profitable. Recent developments in the Combination show that this property will compare favorably in production with the Mohawk."

The disagreeable, if not malicious, character of your editorial is emphasized by the fact that you had full knowledge, at least, of my public utterances on this subject as they appeared in the company's annual report, since you saw fit to comment editorially at great length thereupon in a recent issue of your journal, to which I deemed it quite unnecessary to reply, for the reason above stated, namely, that I was quite content to allow my opinions with respect to the possibilities of development of our property to stand before the world in contrast with yours.

There is another phase of this situation to which I desire to invite your attention. You will readily recall that I left Goldfield during the latter days of February and did not return until the afternoon of the 14th of March, and you will probably remember that between the 9th and the 11th of March I had the pleasure of an extended conversation with you in San Francisco, during the course of which I informed you that advices from Goldfield had revealed to me the fact that our mill-heads had run up to \$100 per ton during my absence; that I could not definitely determine the real cause of this condition until

I had returned to Goldfield and made personal investigation, but that I believed it was due to the ore from this new Combination working. When I arrived back in Goldfield on the 14th, I made a verification of the assays and other necessary investigations, and on the evening of the 16th I sent a telegram in the following language to the directors of this company, all of whom were absent from Goldfield excepting myself, and most of whom were in the Far East:

"Combination new orebody is proving a bonanza. Last 14 days produced \$300,000. Average everything extracted to date \$190 per ton. Reasonable estimate ore opened up \$4,000,000. How much more cannot be estimated without more development. Centre streak assays in the thousands and will be difficult to treat locally. May have to ship some to smelters. Orebody on two levels and 30 ft. wide in places. All directors notified."

This telegram, as I say, was sent on the evening of the 16th, and was received by the directors of this company on the morning of the 17th. On that same morning the secretary of this company issued and gave to the local press an official public statement, and the same appeared in the afternoon papers of that day; so that rather than the information having been "given weeks after the event, at the close of a period during which bear tips have been circulated," it was continuously referred to in the company's reports, and finally reached the directors and the public simultaneously, the directors even having no advantage in respect to knowledge of the final developments over the public itself.

To the undersigned, your editorial appears to be unnecessarily misleading (because you had read our annual report), and mendacious to a degree bordering upon personal affront. For this reason I have departed from my customary practice of ignoring editorial comments, and have cited to you facts which you already knew. I did not reply to your editorial criticisms of our annual report, because I felt that the report was of a character that needed no defense; but I may say in passing that this view is, in my judgment, abundantly justified by the fact that of all the comments I have seen upon the report, both in public prints and a large number of letters received in my office, yours was the only one not of a highly complimentary character. I ask, now, that you shall permit this letter to appear in the columns of your next issue, failing which I shall exercise the right to give it publicity otherwise.

J. H. MACKENZIE,

Goldfield, March 29.

General Manager.

[This letter would have appeared in our last issue but for the fact that this part of the paper goes to press on Mondays. No reflection upon the manager of the mine was intended nor was it suggested that he failed to inform his directors concerning the results of operations underground. Our comment referred to the inadequate information given to shareholders. Concerning this we have something to say on the editorial page. It remains only to point out that Mr. Mackenzie is incorrect in his use of the word 'malicious'. By reference to a dictionary he will find

that 'malice' involves evil intention. As Mr. Mackenzie knows us personally, he will, we feel sure, on second thought, absolve us from such a charge.—EDITOR.]

Mechanical Elevator.

The Editor:

Sir—In your issue of February 20 and with reference to the report of S. R. Guggenheim, president of the Yukon Gold Co., quoting in part: "Three mechanical elevators were installed, two of which were put into operation during the season of 1908. It is a great pleasure to say that the mechanical elevators, electrically driven, which were designed by our own engineers, and *used here for the first time in any country*, were entirely successful." Mr. Guggenheim is probably not aware of the fact, that this class of elevator was installed at Barkerville, Cariboo district, British Columbia, some eight years ago; this having a daily capacity of 2000 cu. yd. and elevating vertically 110 ft. The efficiency and economy of this class of elevator has long been proved.

J. WRNDLE.

Barkerville, B. C., March 16.

[The first mechanical elevator ever designed was designed by Henry Bryant to work a flat claim in lieu of a hydraulic elevator on Prichard creek, near Murray, Idaho. This was in 1900. The next one was a copy of Bryant's and was made by the Stearns, Roger Manufacturing Co. of Denver, as adapted by George H. Evans for the Gold Pan Mining Co., at Breckenridge, Colorado.—EDITOR.]

The Engineer as a Financier.

The Editor:

Sir—In the discussion of the Mining & Metallurgical Society which you published some time ago, Mr. Merrill said that a large number of promoters did not know or care what they were selling, and he goes on to say that "in the small minority of cases he is honest." Is not that rather hard on the promoters? Is there any specific reason why he should be more dishonest than his fellow man in the business world? There might be something in it when he has to draw on his imagination at times to answer questions that the buyer thinks of vital importance. Again, he might enlarge on the advantages of the proposition to lure the prospective buyer, for it takes great inducement to make the average man buy mining stock. How much would be sold if the people were informed that their stock would bring 12½% yearly? Not very much! Give to the man who makes mining his business, the details of a proposition, and if he sees a reasonable compensation he will become interested, and if what you say is confirmed he buys. But not so with a layman; you have to picture to him wealth beyond the wildest dreams of avarice, and remove all doubt of failure, to make him take a thousand dollars' worth of stock.

As to the statement that the promoter does not care what he sells or what the deal is, let Mr. Merrill take some proposition on the street anywhere in the country and try to sell it. If it be not full of merit, or if it has a tinge of the 'wild-cat' in it, see

how readily he is told that the organizer does not care to handle properties of that class. If the promoter sells something that brings the purchaser a remuneration, he can go back and sell to him again, and also to his friends, but if it doesn't 'make good' he can't even sell to his friends' friends. I will let the reader judge whether the promoter cares what he sells or not.

The reason so many mining deals fail is not because of dishonesty on the part of the organizer, but on the part of the engineer that makes the report. How many times have we, as engineers, been asked to make a report by some mine-owner, with the understanding that if the sale is made as the result of our report we will be at the melon-cutting. With this Hays Hammond idea in his head it is easy for the engineer to deceive himself to the extent that the vein averages 6 ft. wide, when it is really only 3 ft., and that the values are \$40 per ton, in place of \$15. The report goes to the broker's office, it looks good, in fact very good; he sends down an engineer to re-examine. This engineer goes and stays a couple of weeks with the owner, who treats him like a king, and he gets Hammondized. What happens to the promoter: well, you all know what a reputation they have. I will make the assertion that there are not more than one out of ten mines that I examine that will come up to the statement in the original report, and it takes a well made, fully detailed, and honest-looking paper to get me out of my office.

TOM L. GIBSON.

St. Louis, March 24.

Uses of Aluminum.

The Editor:

Sir—The interesting article on aluminum, appearing in your issue of March 20, coupled with the fact that the price of the metal is to be greatly reduced before the end of this year, has suggested still another use for it. I refer to the use of aluminum as a precipitant for gold and silver from cyanide solutions, in place of zinc. The aluminum could be used in the form of shavings in ordinary zinc-boxes, or as powder in connection with Merrill's precipitation presses.

In 1893 Moldenhauer proposed the use of aluminum for this purpose, and the following equation may be taken as representing the reaction in presence of free alkali:

This method of precipitation is referred to in Julian & Smart's 'Cyaniding of Gold and Silver Ores', page 158, where it is stated that experiments were made on a large scale by Julian in the Rand Central Ore Reduction Co.'s works, and it was found that the accumulation of alumina in the solution proved extremely troublesome. The high price of aluminum at that time also doubtless had an influence against its adoption as a precipitant.

It seems probable that if the alkalinity of the solution is not allowed to become excessive, alumina can not accumulate in it, and as a precipitate would give

no more trouble than the insoluble compounds of zinc which are formed in the zinc-box. As 54 parts of aluminum are equivalent to 195.9 parts of zinc in reducing power, therefore one pound of aluminum will do the same work as 3.6 pounds of zinc. Taking the price of sheet zinc at the factory as 6.25 cents per pound, it is evident that the price of aluminum would have to be 22.5 cents per pound to be equivalent to the zinc, with the advantage in favor of the aluminum of the saving of two-thirds in freight cost. In a large plant this reduction of over two-thirds of the weight of precipitant which has to be shipped to the plant would mean an economy worth considering.

Owing to the ease with which zinc compounds are reduced to metal in the crucible, the refining of zinc-gold-slime is troublesome and expensive. As alumina cannot be reduced to metal during the smelting of the precipitate, finer bullion can be produced at a smaller cost, and some losses of the precious metals avoided.

The fact that aluminum cyanide does not exist in aqueous solution would lead one to expect a reduced cyanide consumption when aluminum is the precipitant. In the case of the precipitation of the gold this saving will not be appreciable commercially, but if the solution contains copper or other base metal which is precipitated by the aluminum, this regeneration of cyanide may prove worth considering. Roughly speaking, the precipitation of one pound of copper from solution will regenerate two pounds of cyanide. Sodium, which is a deleterious impurity in aluminum when used for other purposes, would in this case be a help. Possibly an alloy containing two or three per cent of sodium would work better than pure aluminum, and would cost less to make.

During the last few years no attention appears to have been paid to the use of aluminum as a precipitant, but when the price of the metal goes down to 13 cents or less per pound, the theoretical advantages of its use will make its application worth the attention of cyaniders to overcome any difficulties in practical work.

BERTRAM HUNT.

San Francisco, March 25.

Tailing-Wheel v. Pump.

The Editor:

Sir—I would suggest the use of a jet-elevator similar to the Evans hydraulic-elevator used for elevating placer-gravel or to some form of conveying device. To avoid friction, the discharge-pipe should be vertical and should be made of manganese steel. The tailing should be de-watered by running through a Callow settling-tank or some similar device. The water should be run through turbine pumps to give it the required pressure to act as a jet, and then be conveyed by pipe to the bottom of the elevator, where it would meet the sand. Acting on the sand through the nozzle, it would elevate the whole mixture to the top of the elevator stand-pipe, whence it would run by gravity to the dump.

HIRAM W. HIXON.

Florence, Italy, March 13.

THE UTAH COPPER MINE.

Written for the MINING AND SCIENTIFIC PRESS
By COURTENAY DE KALB.

Commercial ore at the mines of the Utah Copper Co. in Bingham canyon is assumed to embrace that which will yield a gross return of \$2.60 per ton. This conclusion is reached from the official statement that the enterprise would be profitable upon ore having an average copper content of 1.5%, a precious metal content of 0.15 oz. silver and 0.015 oz. gold per ton, a recovery of 63%, and a selling price at New York of 12½c. for the copper. The silver is estimated at 50c. per oz., the gold at \$20.67, the precious metal contribution to the total being therefore 24c., which is an important proportion. The mining costs are reported to be 40c. per ton; transportation of the ore to mill and of concentrate to smelter will figure an average of approximately 30c. per ton. Accordingly a margin of \$1.90 remains, out of which to pay costs of milling, smelting the concentrate to blister copper, shipment of 'blister' to Atlantic sea-board refineries, refining, and marketing, the use of plant, amortization, and to yield a profit. The Utah Copper Co. expects to make copper at a cost of 7½ to 8c. per pound. In the third quarter of 1908 the production of slightly over 12,000,000 lb. was said to be made at a total cost of 8.73c.; in the second quarter of 1908 a similar production cost 8.16c. This is upon a higher recovery than 63%. So satisfactory a result could not be reached were a loss of 37% in handling, concentration, and metallurgical treatment, actually sustained. The ore being utilized at present averages approximately 1.8% copper, and the recovery, according to trustworthy information, is 70%. That alters the figures to 25 lb. copper obtained, worth \$3.12 at 12½c. per pound. On the same ratio of recovery the precious metals would add 28 cents. The total gross return on this basis is \$3.40. Based upon the higher cost of 8.73c. per pound, the outlay per ton of ore would be \$2.18. The apparent profit for the copper alone is 94c., which the precious metals would increase to about \$1.22. The cost of mining and transportation being assumed at 70c., there would remain \$1.48 applicable to milling, smelting, and marketing. The figure of 40c. for mining is said to take account of the proportionate charge per ton for removal of overburden. The ore is mined partly by caving, and partly by steam-shovel. A semi-official statement places the cost of steam-shovel mining at 20c. per ton, by which method 75% of the output is obtained; the ore yielded by the caving system is reported to cost 65c. per ton delivered in the mine-bins. If these results are achieved, 40c. would easily cover the cost of mining, inclusive of fixed charges. Scrutiny of these figures will show that high efficiency and rigid economy are demanded in every detail of operation. An effective answer to criticism is that the methods employed were tested by preliminary work of several years' duration. The company demonstrated the possibility of insuring a profit at the low figures of recovery and price above stated, before venturing the enormous outlay for plant and equipment that now places the Utah Cop-

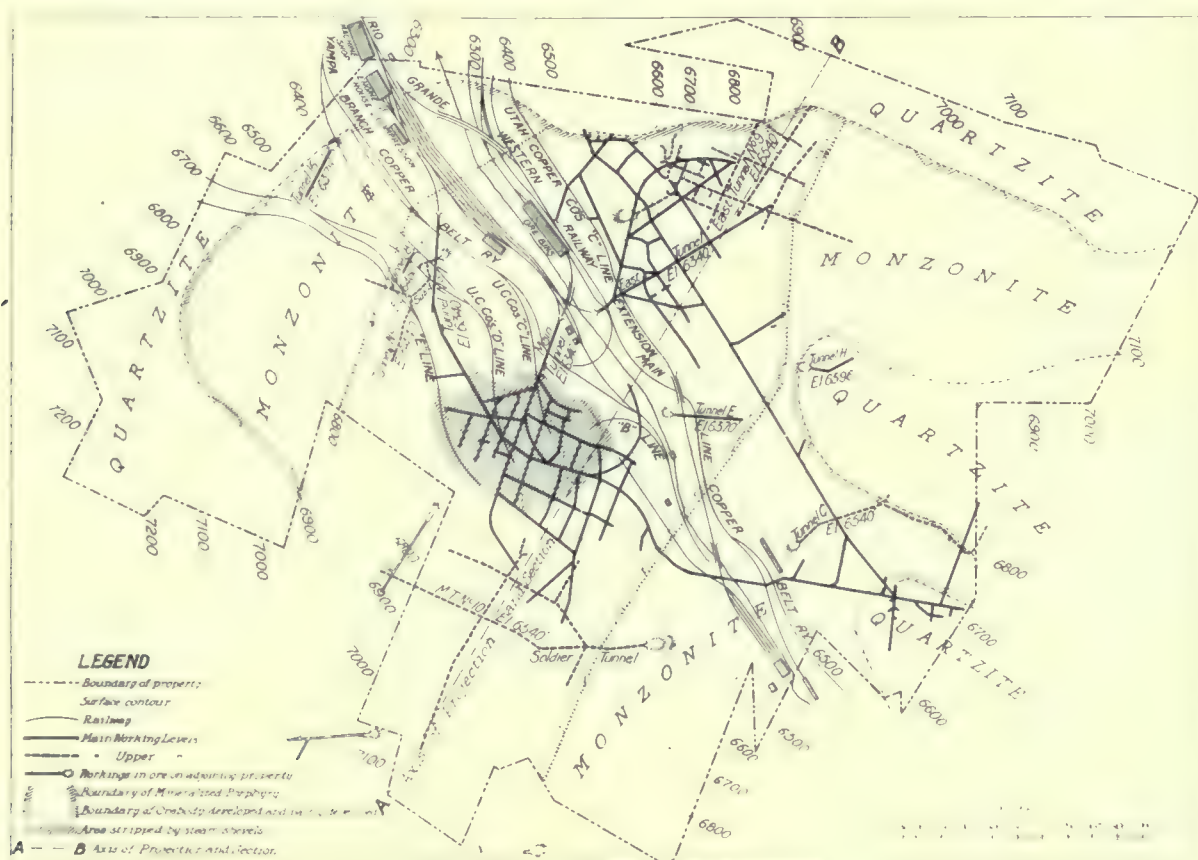

per Co. among the notable metal producers of America. It is to be noted that final calculations were founded on results obtained from ore broken mainly in the course of development. Mining on an economical scale was not started until June 1907, the experimental mill at Copperton, in Bingham canyon, being fed by ore derived from development and cave-mining.

The Utah Copper Co.'s mine is an example of the class of large low-grade deposit, admitting of definite measurement of enormous masses of ore, on which the largest recent copper projects in America have been based. No uncertainty exists in regard to quantity and metallic content. Having eliminated the mine-risk, the remainder of the problem relates to mechanical details of production, with a forecast of minimum market price. The orebody is of the same type as the deposit now being worked by the Nevada Consolidated Copper Co. at Ely. A mass of monzonite exposed on the surface, containing disseminated chalcopyrite, has been superficially leached, resulting in a zone of secondary enrichment below, diminishing in copper content with depth. Thus three concentric zones exist: the overburden, averaging 70 ft. in thickness, containing about 1% copper, mainly present as carbonate; a zone of secondary enrichment averaging 1.8 to 2% copper through a thickness of 310 ft., and a lower zone of undetermined thickness containing 1.5% copper and lower. A striking difference is observed, however, between the disseminated ore of the Nevada and of the Utah monzonite. At Ely a true primary ore is found, the chalcopyrite and pyrite being disseminated through the igneous mass in the form of minute crystals intergrown with the crystals of the original rock; at Bingham the chalcopyrite is present extensively in the form of thin scales and films through a multitude of minute parting-planes and also disseminated perhaps equally as grains. The evidence points to the introduction of copper subsequent to the consolidation of the monzonite. The quite uniform distribution of the metal is remarkable in view of this fact. Zones of greater crushing, silicification, and alteration, however, yield copper in larger amount. These are mainly around the periphery of the intrusive monzonite. In general the character of the monzonite in these two widely separated localities is similar, but the Nevada rock is more highly silicious, the respective amounts of silica being 61.7 and 57.9%. Both are fine-grained, and contain much hornblende with the feldspars, which latter consist largely of orthoclase in both instances. Quartz is nearly absent as an original mineral, and as an alteration product is much more prominent at Bingham than at Ely. In both places the tendency of the outcropping monzonite is to form a depressed surface of even slope, but the exposure in Bingham canyon is the more remarkable in this respect. The peculiarity of outcrop is due, of course, to the greater decomposition of the monzonite than of the surrounding rocks. The superficial extent of the deposit can be seen at a glance by the abrupt change from the flowing slopes of the monzonite area to the jagged outcrops of the enclosing quartzite. The mineralized porphyry

which has been explored, underlies 80 acres; this has been developed sufficiently to admit of an estimate of 1,000,000 tons of ore per acre. Twenty acres have been fully developed, and sixty more have been extensively tested by drifting and boring. While ores containing 1.5% copper, or even less are com-

that the secondary enrichment has produced a zone of workable ore concentric with the slope, so that the dividing plane between the two properties, in workable ground, will not be more than about 340 ft. high.

Coming back from this digression it appears that

Map of Utah Copper Company's Property.

Section on AB of Map.

mercially profitable, the 20,000,000 tons of proved ore will average higher than 1.8%. The total area of mineralized monzonite within the limits of the property is 160 acres, and the belt extends into the ground of the Boston Consolidated Copper Co. to the southwest. Bingham creek flows in a deep ravine northwestwardly across the area to be mined. The slope of the canyon on either side is 40% near the base, gradually steepening to 45% near the upper portion of the monzonite. A cross-section shows approximately 1400 ft. of ore on the northeast, and 1850 on the opposite side which lies contiguous to the Boston Consolidated; but it must be remembered

the mining problem presented is that of excavating a mass on two sides of a creek, having an overburden 70 ft. thick, below which lies 310 ft. of valuable ore. Adits driven each way from creek-level pass into ore of lower grade than 1.5% copper, at a distance of about 900 ft. from the portal. Beyond the adits the ore, following the surface-angle, extends 500 ft. on the northeast from what is called the East Tunnel level, and 1000 ft. up the slope from the end of the Main Tunnel level on the southwest side. The property consequently is divided into two nearly equal portions, one constituting ore available above and upstream from the present levels, and the other lying

below and down-stream, which will be mined in the distant future. A simpler situation for economical mining would be hard to duplicate. From either side the ground can be worked back in a series of terraces, by steam-shovel, and the slopes are not so steep as to occasion an excessive prolongation of track-mileage to serve the different terraces by a switch-back railroad system. This system comprises 13 miles of track. The maximum grade of the road is 4.6%, and it climbs the mountain sides in 9 laps to a height of 400 ft. above the main loading-bins at the mine-mouth. The locomotives used weigh 50 tons, and two are required to take a train of 10 empty six cubic yard cars up the grades. The overburden is handled in six-yard dump-cars over stripping tracks, constructed on a level. One locomotive can easily haul trains of 20 loaded dump-cars over these level stripping-tracks to the waste-dumps in gulches on adjoining properties where space has been purchased for that purpose.

In order to prepare the ground for steam-shovel excavation two methods are available; one is to strip the overburden by steam-shovel after 'springing' and blasting the bank with deep shots in holes bored by Keystone drills ahead of excavation, as is done at Ely, and the other is to undermine it by caving, which is the present practice of the Utah Copper Co. to a limited extent. It is claimed to be somewhat cheaper per ton to undermine than to 'shoot' and excavate under certain conditions. The calculation takes into account the reduction in the number of terraces which occurs from having previously brought down the upper portion of the orebody, and the consequent extra mileage of railroad needed, with transportation costs during the process of stripping. Three laps of railroad, corresponding to an elevation of 325 ft., which would have been needed to reach the benches in stripping by steam-shovel, are thus saved. The problem is too complicated to suggest probabilities of comparative cost of the two methods after no more than a superficial inspection. If the ore won by caving actually costs only 65c. per ton the statement would seem to be fully credible, but the costs of caving as conducted in the Utah Copper mine must be quite variable. A large amount of ore would have to be mined more cheaply than 65c. to strike the average claimed, namely, 40c., since a great deal of it certainly costs as much as \$1.25, or more, per ton. The introduction of the steam-shovel was determined upon after the orebody had been extensively developed for cave-mining. A large initial expenditure in adits, drifts, and raises was made before the adaptability of mechanical excavation was demonstrated. It is now shown that the caving system results in no financial advantage over the alternative method of stripping, even so far as the present workings extend, and it is being rapidly abandoned.

The caving system as adapted to the Utah Copper mine is not a direct application of the methods followed in the Lake Superior iron region. Two principal adits or tunnel-levels were driven from the surface, penetrating the orebody to the limit of 'commercial ore.' From these levels drifts, or galleries,

are run in both directions, and connected by cross-cuts. Between the lower and upper main-levels intermediate levels are driven, and likewise the ground above the upper level is dissected by sub-levels, drifts, and cross-cuts. The vertical distance between the main-levels is 200 ft., and from the upper main-level to the surface at the highest point is nearly 350 ft. The intermediate levels were originally spaced 17 ft. apart vertically, but the distance between later levels was gradually increased to 25, then to 33 ft., and in future the distance will be 50 ft., thus materially raising the ratio between the tonnage of ore removed by blasting and by caving, with the intention of correspondingly reducing the cost. From the lower gridiron of drifts and cross-cuts 14 raises were extended up to the overburden, serving for ore-chutes in an area approximately 800 by 500 ft., making an average of one main raise to a block of 70 ft. square on the lower level of the mine. The mine is not laid out so systematically as this would seem to imply. The raises all incline toward the outer edge of the orebody at angles varying from 50 to 60°. Within each prism penetrated by a raise, branch raises are driven near the capping or overburden, and from the principal branches sub-branches are in turn driven as the workings come nearer to the overburden. Thus the system of raises assumes the shape of a leaning tree, branching out against the capping of oxidized low-grade rock. The weakening of the ground becomes progressively greater toward the surface, and the pressure crushes the skeleton of pillars. The whole mass settles quite evenly, bringing the overburden down in a body which alternately fractures itself and re-consolidates under pressure. The number of these branches is such that on the level where caving is to be effected one such opening into the system of raises exists for every 12 by 12 ft. of horizontal cross-section, the sub-raises being 5 by 5 ft. From this the ratio of ore blasted to ore caved would be 1 to 5.76, but unfortunately so favorable a ratio cannot be attained. Although the ground thus weakened sometimes starts to crush without further assistance, and occasionally comes with undesirable celerity because of 'slips' which have been formed in the process of alteration which has taken place throughout the rock, the regular practice is to widen each raise on the sub-level immediately below the overburden, giving it a funnel shape. Thus the pillars are narrow at their bases, and spread out overhead after the manner of groined arches. If this does not produce signs of movement in the superincumbent mass the roof is further weakened by over-hand stoping. Finally the collapse is hastened when necessary, by shooting down a number of pillars.

In order to further elucidate the method of honey-combing by branched raises the accompanying illustrations have been prepared. They are not taken from the mine map, but are from freehand sketches, representing the system in principle. In Fig. 1 is shown an ideal section with levels, intermediates, main-raises, branches, and sub-branches. The workings extend through the ore to the overburden. In the figure the branching of raises, with their funnel-

Steam-Shovel Mining, Utah Copper Mine.

Switch-Back Railroad, Utah Copper Mine

shaped upper termini are depicted, together with the arch-stoping. It will be seen from these that great pressure is thrown upon pillars of narrow base. An important point in controlling the movement and the crushing of the ore is to prepare a sufficient area for caving. This necessitates concentration of mining operations in a limited area so that it may be uniformly 'honey-combed'. The result is economical, but it would appear to possess the disadvantage of risk of sudden collapse. The management states, however, that such is not the case. The total area which is undermined is large, but the avenues for retreat are numerous. The method certainly does not admit of control of caving so as to confine it to definite boundaries. This is one serious criticism to which it lies open.

After an area has been caved the crushed ore is drawn off through the raises from below until the barren overburden appears. Drawing is then stopped until the ground between that level and the next intermediate level below has been similarly honey-combed and caved. The overburden so far consolidates after each caving as to follow the ore as a blanket, without mixing with it, and large areas which have broken and settled are observable on the surface. The cost of driving the levels and raises is about \$2.50 per running foot for an average cross-section of 6 by 6 ft. The actual ratio of ore won by blasting and by caving is approximately 1 to 3. The total length of underground workings is nearly 24 miles. Timber is used only for keeping open the main gangways where the ground is weak, and for building chutes. The total timber expense is only a fraction of a cent per ton of ore mined. Trimming is done by hand on all but the lower main-level. Electrically operated trains of double side-dump cars, having a capacity of 48 cu. ft., convey the ore on a 24-in. gauge track from the bottom of the main raises to the loading bins in the canyon, whence it is shipped by standard gauge railroad to the mills at Copperton and Garfield. The daily output from the mine, exclusive of the ore excavated by steam-shovel, is 1500 tons. The mine-tramway branches into four tracks above the bin which has a total capacity of 6000 tons. The elevation of this tramway is 6340 ft. above sea-level.

Cave-mining prepared the area which is now being excavated by steam-shovel on the southwest side of Bingham creek. The upper portion of the orebody, however, was not reached. This is equivalent to saying that the adaptation of caving to the preparation of the ground for subsequent mechanical excavation was not done at this point in the systematic manner with which it is being applied in the direction of the northeast boundary. The reason it is being done at the northeast boundary of the orebody is because there is in that portion a high isolated body of ore which it is best to mine by caving, thus dropping the overburden down to an elevation where it can be handled over one of the present stripping-tracks. The overburden, which had been loosened and crushed by caving, where shovel work is now in progress, has been nearly stripped, and the customary methods will have to be applied to the higher and more diffi-

cultly accessible portion of the deposit. The stripped overburden is stored in the canyon above the copper-bearing area, and will be cheaply accessible if, in future, leaching of this low-grade carbonate ore can be done at a sufficiently low cost. If the production of large quantities of sulphuric acid from fume be necessitated as a condition for the continuance of the smelting industry in the Salt Lake valley, this overburden may constitute a convenient means for consuming a fraction of it. The company owns eight steam-shovels, of which seven are of the Marion model, and one a Vulcan. A 65-ton Bucyrus shovel has just been ordered. Only two shovels are continuously employed on ore, one other being used part of the time for loading ore and part of the time on overburden. Three 95 and two 65-ton Marion shovels are stripping overburden. The usual crew, consisting of shovelman, craneman, fireman, and six pit-men, are employed with each steam-shovel. The output per shovel is about 600 cu. yd. per shift of 10 hr., and the coal consumption will average about 2½ tons per diem for each machine. Water for the boilers is piped 2 miles. It is free from scale-making salts, having been used on 18 month campaigns without trouble. The results of operation have shown that 90% of possible shovel-time has been productive, only 10% being lost for maintenance and repairs.

The great pit in which mining is being conducted starts near the creek on the 6340-ft. contour. The area stripped is 15 acres, nearly 0.8 of an acre being laid bare per month, equivalent to 87,000 cu. yd. The work of mining the ore with steam-shovels is advancing entirely on the bottom level, the upper bench being merely the top of the ore, with a 60-ft. wall of overburden beyond, on which the stripping-shovels are working. The experiment of reducing costs by avoidance of terracing has been carried to the extent of working with steam-shovels against a wall of ore 220 ft. high (Fig. 2), and the endeavor will be made to mine the entire thickness of commercial ore in one bench, which would be 310 ft. high. The angle of the wall is about 55°, and it has stood the test of exposure to one winter season without sloughing. The face is shattered by heavy blasts, and afterward 'trimmed' by a gang of men, working with the aid of a rope, using bars to pry off and throw down the loosened masses. The ore thus forms a talus at the bottom of the artificial cliff, where it is available for the steam-shovel. Now and then an avalanche of ore tumbles upon a shovel and buries it out of sight, but the number of accidents has been very small in view of the peculiar risks which are taken. The ore 'stands' well, as may be judged from this: it is not 'blocky,' nor do many 'slips' occur. Such parting-planes are generally of large extent, are readily discernible, and the movement of large masses can be anticipated. Thus accidents are preventable in large degree.

The method known as 'bank-blasting,' familiar to all hydraulic miners, is employed for loosening the ground. It is locally, and not inappropriately, termed 'gophering.' Little adits, only 2 ft. square, are driven into the ore, perpendicular to the face, for a distance of 30 to 40 ft. At the end, drifts at right

angles extend in both directions, making an excavation in the form of a T (Fig. 3), the cross of the T being from 50 to 60 ft. in total length. In the cross are stowed from 30 to 60 kegs of FF powder, primed with three to four 30% dynamite cartridges, tamped with broken ore, and fired by an electric battery. One blast will loosen as much as 60,000 tons. The zone shaken by the blast 'tails out' 60 ft. on either side, that is, the shattering extends about 180 ft. horizontally, and 120 ft. in height. In selecting a site for a 'gopher-hole' the ore is examined carefully for

Fig. 1. Caving System, Vertical Section

slips, as the blast is entirely ineffective across such planes of division. The ore falls in masses which are often of immense size. Therefore drilling and blasting are constantly in progress on the ore-pile at the base of the bench-wall.

The ore as mined in the open pit carries from 4 to 6% moisture. The bottom of the pit is exactly on the level of the ground-water. Above this horizon it is estimated that 60,000,000 tons of ore are avail-

Fig. 2. Mining by Steam-Shovel.

able. At the present time the total output of ore is nearly 6000 tons per diem, of which a little less than 75% is won by steam-shovels, but the proportion is increasing, and in about two years all underground production from the Utah Copper Co.'s mine will cease. If steam-shovel mining can be maintained at a cost as low as 20c. per ton, as unofficially claimed by the management, it will be a remarkable achievement. The manager states, however, that the average costs for the past 18 months have been less than 20c. per ton, and that the work is being so improved as to reduce that figure to a still lower level. It may be accomplished when all is favorable, but it certainly allows for no contingencies, nor for increasing cost as the higher portions of the orebody are

reached. But the company earned a net profit of nearly \$500,000 in one quarter of 1908, with copper selling at 13c., which is near the basal price on which the enterprise was founded, and the cost of the ore in the shipping-bin was certainly not less than 40c. per ton. It is equally certain that the cost can be

Fig. 3. Bank Blasting.

maintained below that figure when mining is conducted exclusively by steam-shovels. This great deposit of low-grade ore has been known for many years, but the development previously done was in the hope of finding zones of high enrichment. It required the gift of what is called today, in a semi-commercial sense, 'imagination,' to plan the utilization of a mass of ore which possessed a copper content no higher than 1.5%. To D. C. Jackling belongs the honor of seeing the possibilities, of convincing those who held the financial sinews for so gigantic an enterprise, and, in the light of results, the validity of his forecast stands unchallenged.

The comparatively thin but widely extended salt deposits of the world, such as the Silurian deposits of the New York-Ontario area, are the result of 'salt-pan' evaporation. Salt, however, is readily dissolved by water at ordinary temperatures. Cases where such brines have been evaporated and salt precipitated may be observed in nearly every part of the world. If, as in Hungary, the bed formed in the regular 'salt-pan' way, near enough to the surface to be mined, is folded, faulted, and traversed by thermal waters from volcanic vents, it may often require care and patience to distinguish between primary and secondary deposits. If, however, the 'salt-pan' salt is at a great depth, yet subjected to the dissolving power of artesian waters, such waters necessarily being hot at the depths postulated, then the resulting solutions, if saturated at such high temperatures, are obliged to part with their salts as the surface is approached. Growing crystalline masses result, and dome structure follows. Such occurrences are found at Petite Anse and other points in Louisiana.—*Economic Geology*.

DRY CHLORINATION OF SULPHIDE ORES.

By F. W. TRAPHAGEN.

*Any process that is sound in theory ought to be successfully put in commercial operation. It seems that this applies to the process of dry chlorination of sulphide ores, which is now attracting so much attention. The use of chlorine in one form or another is not new to metallurgy, and this element has been the means of adding many millions to the world's store of wealth, chiefly through its use in chloridizing roasting for pan-amalgamation, hyposulphite lixiviation, and in the vat and barrel-chlorination processes. The proposed new process, however, is totally different in principle from any of the above, for while they require air in the preliminary operation of roasting, it is indispensable to the success of the new process that oxidation be prevented and that the operation be carried on so that chlorides are the only products formed.

Reference to the accompanying table will show how important this point is; for it must be borne in mind that the tendency, when chemical changes are

400; cupric salts, 10,100 and 51,400; lead, 20,200 and 83,900; ferrous salts, 24,000 and 82,220; manganous salts, 45,600 and 112,000.

In carrying out the process care is taken not to introduce an excess of chlorine, so that only the protochlorides are formed. More energy is developed, and the higher chlorides are formed when the partly chlorinated mass is discharged into water and treated with additional chlorine and steam. This brings all the metals into solution, when they are passed through filter-presses with wooden frames, and separated from the insoluble gangue and sulphur. The metals may then be successively precipitated by displacement: gold and silver by copper; copper by lead; and lead by zinc. The reduced iron and manganese chlorides are perchloridized by steam and chlorine gas, and precipitated by zinc oxide. The solution thus freed from all the metals save zinc, is evaporated to dryness and the resulting zinc chloride electrolyzed with the production of metallic zinc and the regeneration of the chlorine. Theoretically about 22 lb. of zinc should be produced per hp.-day; actual results have been somewhat better than half this fig-

HEATS OF FORMATION OF SULPHIDES, OXIDES, AND CHLORIDES.

Manganese (ic)	87.0	125300
Zinc	97.0	43000	81.0	84800	136.0	97400	113000

The heats of formation in the above table are given in gram-calories per gram-molecular-weight for each compound.

taking place, is for those compounds to form which in their combination produce the maximum heats of formation. Furthermore, when conditions, especially temperatures, are favorable, these tendencies are the more marked the greater the differences between the heats of formation of the existing compounds and of those which may be formed by the re-combination of the elements. Where the heat of formation of the possible new molecule is but slightly greater than that of the original molecule, the elements show but slight disposition to make new combinations, and the application of external energy is necessary to affect a change.

Keeping these points in mind, it is seen from an inspection of the data in the table that the heat of formation of zinc chloride, for example, is more than double that of its sulphide, while the oxide possesses a value almost equal to that of the chloride. In like manner, the heats of formation of the sulphides and chlorides of the other elements are respectively: silver, 3000 and 29,000; cuprous salts, 20,300 and 35,-

ure, and with improved devices may be expected to reach as much as two-thirds of the theoretical figure.

The field of usefulness of this process is large, the most promising one being the treatment of those ores that have so long been a source of trouble, namely, the complex lead-zinc ores that could be marketed only by sacrificing one or other of the valuable constituents. The process is peculiarly adapted to the treatment of such ores, and much is expected of its development and success in that direction. Like many other processes, this is not new; and while Baker and Burwell, Swinburne and Ashcroft, and Alf. Sinding-Larson deserve credit for their part in its development, they were far from being pioneers in the use of dry chlorine gas with ores, patents having been issued for this purpose as early as 1868.

Water or any liquid kept in a wooden pail is apt to taste of the wood. To prevent this, says the *Practical Carpenter*, fill the pail with boiling-hot water and let stand until the water is cold; then empty the pail and wash the inside with a solution of soda in lukewarm water, with a little lime added.

*Abstract of paper in the *Western Chemist & Metallurjist*.

METEOR CRATER.

Written for the MINING AND SCIENTIFIC PRESS

By JOHN B. HASTINGS.

In Longitude $111^{\circ} 1'$ west, latitude $36^{\circ} 2'$ north, and five miles almost due south of Sunshine, a station on the Santa Fé railroad, in Coconino county, Arizona, is an interesting and now well known phenomenon called Meteor Crater (formerly Coon Butte). It has been visited and described by G. K. Gilbert, D. M. Barringer, B. C. Tighlman, G. P. Merrill, and H. L. Fairchild, and the following notes have been compiled from the writings of all these authors, except the report of Mr. Gilbert, which is unattainable.

It may be said, however, that Mr. Gilbert deems the crater an ordinary volcanic butte, the result of a steam-explosion, even though there are no volcanic rocks in the vicinity. The other authors believe that the crater was formed by the impact of a meteorite,

strata composing the butte dip quaquaversally 5 to 10° from the centre, this shallow dip being complicated by faulting, creating high local dips, from 60° to an overthrust. The geological column, from the surface downward consists of 30 ft. of red sandstone, then 200 to 350 ft. of yellowish-gray calcareous sandstone called the Aubrey limestone; then 800 to 900 ft. of light-gray, almost white, fine-grained sandstone; and under this a thin stratum of yellow sandstone, the thickness not definitely known. It seems, however, to be the uppermost member of the Red Beds, which the U. S. Geological Survey says are 1000 ft. thick. These sediments belong to the Grand Canyon series of the Carboniferous, and extend 70 miles in every direction, except where occasionally interrupted by volcanics, the nearest of which are 12 miles southeast.

The outside slopes of the butte are composed of red sandstone, Aubrey limestone, white sandstone, and a few yellow and brown sandstone fragments.

Meteor Crater.

Another View.

like a depression in an iron plate from a cannon ball. I was on the ground in the spring of 1907, but only for three hours—long enough to walk around the crater and have a talk with the mine superintendent. The shortness of the visit and my ignorance of literature on the subject, made my impressions nearly valueless, but from casually examining many pieces of the silica, I thought it was the result of ascending hot waters, and that probably the pit was caused by the erosion of an underground stream, which, after its work in solfatarism, had carved for itself an outlet, and that the perpendicular circular walls resulted from a combination of faulting causing the uplift, and perpendicular jointing in harder beds underlain by softer. I had not time to examine the nature of the material of the outer slopes. This conception I find has been considered and discarded by capable men.

The butte is circular, 3950 ft. diam. in a northerly line, and 3850 ft. from east to west; it is 120 to 160 ft. high above the level plain, and the crater or internal pit is 600 ft. deep. Before Meteor Crater was formed its site was probably occupied by a flat topped butte of considerable area, rising not over 30 ft. above the limestone plain, a remnant of a red sandstone bed of that thickness. The uppermost

The limestone blocks range in size from 5000 tons, down to silica in microscopic fragments (pulverized sand grains). Many large fragments of the limestone have been hurled a mile from the centre of the crater, and others of 50 tons more than a mile. The greater number of the limestone boulders, up to 5000 tons, are on the slopes outside of the crater in an east and west line through centre. There is no order in the distribution of the fragments, except the limestone on this east to west line. Small pieces of sandstone are found in small quantity on the surface on the south and southeast portions of the rim, which are almost certainly from the Red Beds, 1000 ft. below. On the whole, there is vastly more fragmentary material to the southwest, south, and southeast than in the opposite directions, and it is more comminuted. The limestone cliffs inside the crater are more shattered to the southwest and south, and the limestone bed is raised higher. To the southeast is the great wedge at the fault in the cliff rim. The larger fragments, of 10 tons and upward, are also further from the crater on the south and southeast sides. The lowest point on the rim is on the north, a little west of a north and south line through the centre. All this shows that the force acted more violently in a southwest, south, and southeast direc-

tion. There is a little red sandstone butte one-half mile north of the hole. Over this a jet of the crushed material and rock was spurted, falling on the near slope and across the top, and on the plain beyond for a few hundred feet, but being absent for 50 ft. on the north or lee side of the hill.

From topographic surveys Gilbert found the contents of rim and hole about equal, and judged there was not room for a large buried meteor. Tighlman, judging from surveys, thinks the rim is short many million cubic yards of the quantity necessary to fill the hole, and that if there had been a steam-explosion, large quantities of the fine material would have been blown entirely away, and consequently there might be a deficit allowing room for a buried meteor.

The inside slopes of the walls of the 600-ft. crater are very steep, in places perpendicular, until near the bottom of the Aubrey limestone, where there is an extensive talus of red sandstone, limestone, and gray and white sandstone, reaching 1000 ft. from the walls, leaving a flat central plain in the 3800-ft. hole 1800 ft. diam. The talus generally extends for 400 ft. on a 6° slope under this central-plain area. Near the centre five prospecting shafts from 30 to 200 ft. deep, and five drill-holes 305 to 1003 ft. deep, have been sunk in search of the buried meteor.

A lake has occupied the crater in recent times and deposited 100 ft. or more of lake-silt in the centre of the hole; below the lake beds is 300 ft. of almost impalpably powdered rock, consisting of 95 to 99% silica, with red sandstone, yellow limestone, and white sandstone boulders scattered indiscriminately through it. For the next 200 ft. the powdered rock gets continually coarser, and contains more of the unbroken sand-grains, until it is almost entirely gone. North 15° East, 510 ft. from centre of the hole the rock in place was struck at 147 ft., and proved for 53 ft. by a shaft, while at 250 ft. south-east of the centre it was 890 ft. deep, as proved 113 ft. by a bore-hole. In the shaft the rock dipped downward and outward, corresponding to the rock exposed in the crater walls, but was more shattered and disintegrated; in the drill-hole it was hard. The silica or rock-powder is very fine, much of it passing a 100-mesh screen, and it is supposed to have been formed from the white sandstone underlying the Aubrey limestone by the impact of the meteor. Thus it would be the result of crushing, and not of heated waters. Barringer, Tighlman, and Fairchild think it was thus made instantly; Merrill assumes that the pumiceous portion resulted from heating of the water contained in the sediments from heat generated by the impact, and that in fact the water was converted into steam, which furnished explosive power, and aided the impact in forming the hole. Under the microscope some of the broken sand-grains are half as large as the original grains of the sandstone, but the vast majority are much smaller, and many are invisible under an ordinary lens. The minute fragments are clear transparent quartz, looking like broken ice; they are of every conceivable shape, with sharp edges, and translucent; but much is impalpable powder. It is sometimes coarse enough

to be gritty between the teeth, but no particle is larger than the grains from the original sandstone. After formation this silica poured out over the edge of the hole like flour out of a barrel, and practically composes the rim-slope, but is everywhere mixed with angular sandstone and limestone, with exposed blocks of all sizes on the surface. Where observed inside the crater, the sandstone under the limestone is altered in the same way. The effect of this incoherency in the sandstone would be expansive and should arch the beds into the quaquaversal dip observed.

The meteor is thought to have been at least metallic on the outside, and 2000 pieces of iron weighing from 1000 lb. down to a fraction of an ounce, have been found round about the crater, and as far as 2½ miles away, amounting in all to about 15 tons. They are known to collectors as the Canyon Diablo siderites. Four pieces weighing 3 to 4 lb. were found inside the crater. These siderites contain a trace of silicon, sulphur, phosphorus, and sometimes of platinum and iridium, 1½% carbon, 8 nickel, 90 iron. Also black diamonds, esteemed the most interesting of all such occurrences, are found. Besides the iron fragments, or siderites, many pieces of iron-shale have been found; seven weighing from 1 to 30 lb., coming from a shaft 48 ft. deep inside the crater. These shales are in general composed of hydrated iron oxide, with sometimes a kernel of siderite; they also contain some magnetic iron oxide, green hydroxide of nickel, iridium, and platinum. The iron-shale is thought to be an oxidized product from the siderites, or else portions of the meteorite rich in chloride and sulphide of iron. These and the magnetite are found attached to some of the iron specimens. The magnetite is thought to have constituted the tail of the meteor. The magnetite is described as fused and massive, and at the same time stratified and laminated. In general appearance it is different from any terrestrial magnetite. The magnetite in fine particles is generally distributed in the crater-filling, and occurs in several forms, such as scales like those produced in forging iron, or as small brown particles, and also as blackish-gray, rather fine-grained powder, strongly attracted by a magnet. This is crystalline in structure, though not in shape. It is sometimes round like shot, as if condensed when falling; it exists as a cement or partial coating of sand-grains, and also as a coating over metallic iron globules. Rock-fragments cemented by the iron oxides into dark lustrous masses occur, which suggest fusion, but Fairchild says it is from solution. The iron or 'siderites' are thought to have been torn loose from the meteor under the strain of expansion, when that body at the intensely low temperature of outer space, entered our atmosphere. The fragments then fell behind the meteor itself, and reached the earth after the catastrophe. Since working the property in April 1904, Barringer saw a meteor fall in central Arizona, from which five drops were detached. If these were large enough to escape entire combustion they would reach the earth as fragments separate from the meteor.

In the 15,000 ft. of shafting and boring done no

large meteoric mass has been found, but in one of the drill-holes impassable obstructions were found, and a magnet brought up material assaying 0.4% nickel. Gilbert made magnetic surveys to test the meteoric hypothesis without finding any disturbing influence. Tighlman suggests as an explanation that the meteor may now consist of polarized fragments forming a series of closed magnetic circuits with practically no external field. Experiments showed that individual pieces of the iron-shale, from an inch down to a mere grain, exerted an influence upon a magnet, but that an aggregation of grains did not. Mr. Tighlman is quoted as an authority on projectiles, and he says that a projectile will form a shallow crater five times its own diameter, and the crater will still be round when the impact is 20° from the vertical, so a 500-ft. body, traveling five miles per second, might make this crater of 4000 ft. diam. and 600 ft. deep.

The shafts and drill-holes have been sunk by the Standard Iron Co. of Philadelphia, in which Messrs. Barringer and Tighlman are the prime movers. They hoped to find meteoric material of economic value, especially rich in the rare metals. Thirteen drill-holes at depths of 400 to 680 ft., in a zone 20 to 100 ft. thick, found meteoric material in the crater-filling as follows: (1) silica cemented into greenish lumps, (2) a black vitreous material, (3) grains of native metal (sreibersite?). All three contained iron and nickel. Fourteen holes reached solid rock at depths of 600 to 720 ft., while two others, close to the centre, went 1030 ft. deep for a solid core. Cedars 700 years old are growing on the rim, so the age of the crater is put at a few thousand years. This records a startling physical event. It would be interesting if the hole should really prove to be the result of solfatarism, and if the somewhat elusive meteoric elements within it were to be traced to the same source. It would ally itself to the irons of Ovifak.

Mining has the greatest future of any Siberian industry. Gold in placers is the chief mineral product at present. The chief centres of gold mining are the Altai, the Marinsk district of Tomsk, the southern parts of the province of Yeniseisk, the Ynisk district in the north of the same province, the Nerchinsk and the Vitim districts of Transbaikalia, the Olekma and Vitim districts of Yakutsk, and the Bureya and Zeva districts of the Amur province. Some gold is also extracted by the Chinese in the south Ussuri region. No statistics as to the amount of gold produced in Siberia can be obtained, as the figures are contained in the total output of the Russian Empire.

Mushet steel was not, strictly speaking, high-speed, but it was at any rate the forerunner of high-speed steel, and the development of the latter grew out of the former. The composition of the original self-hardening steel, R. Mushet Special is:

	%
Carbon	2.0
Tungsten	5.0
Chromium	0.5
Manganese	2.5
Silicon	1.3

REFRIGERATION WITH ETHYL CHLORIDE.

Ethyl chloride is the monochloride of ethyl (C_2H_5Cl). It is the product of ethyl alcohol treated with hydrochloric acid gas. It is a colorless liquid with a specific gravity of 0.925 at 23° F. (specific heat, liquid, = 0.4276; gas = 0.272). Its boiling point under atmospheric pressure is 54.5° F. Its critical temperature is 365° F. (under a pressure of 53 atmospheres), and its latent heat is 174 B.T.U. at 23° F. It is a neutral chemical and shows only the slightest trace of acid upon litmus paper. It is neither deleterious nor obnoxious, and should it be necessary at any time to repack the valve stem or the stuffing box of the compressor no inconvenience is experienced from escaping gas. It possesses nothing in common with either air or water, consequently, should by accident either of these elements be introduced into the system, no chemical change would occur. As the critical temperature is high, there is no generation of permanent gases to impair the efficiency of the refrigerating system, and it does not deteriorate in value as a refrigerating medium. It is apparently just as good and efficient after a year's use as when first made. Its boiling point being high, it has a correspondingly low point of liquefaction under pressure, namely, 15 lb. per sq. in., gauge pressure, with condenser water at 65° F. Its pressure being low, the loss of chemical in action from leakage is reduced to a minimum. Its low pressure, together with its being a neutral, insures long life to the machine. It is not, however, applicable for sharp freezing or for temperatures of zero or below, but it is a favorable chemical in the manufacture of ice and in the production of the ordinary storage temperatures. Ethyl chloride approaches nearer to the ideal chemical for refrigeration than any other now in use. It seems destined to a prominent place in that field, not only on account of its stability and the ease with which it can be handled in a machine, but also from the fact that in the near future it will be manufactured from denatured alcohol, free from government tax, which will make its cost practically the same as several of the other chemicals used in mechanical refrigeration.

C. C. PALMER, *Trans. Am. Soc. Ref. Eng.*

The average annual production of pig-iron in the Ural and Siberia (separate statistics for Siberia not given) from 1902 to 1906, inclusive, was 657,440 tons. The Siberian output of coal, chiefly from the province of Akmolinsk, rose from 660,770 tons in 1902 to 1,325,400 tons in 1905. Copper is mined in small quantities. More and more foreign capital is becoming interested in the mineral wealth of Siberia, and American miners are prospecting in those parts of the Primorskaya opposite and near Alaska. The engineers of the Trans-Siberian committee have undertaken to thoroughly investigate the mineral resources of Siberia, and have discovered oil wells at Soudjenka and Teheremkovo, which furnish some oil for the Trans-Siberian railway.

To find tons of rail in one mile of track, multiply weight per yard by 11 and divide by 7.

COMPANY REPORTS.

SKIDOO.

The Skidoo Mines Co., of Los Angeles and Skidoo, publishes a report for 1908. Skidoo is a camp in Inyo county, California. The president is E. A. Montgomery, who signs his name E. A. (Bob) Montgomery. Charles M. Schwab is a director. H. W. Squires is superintendent at the mine. The plant includes a 10-stamp mill, with a cyanide annex. Five more stamps are being added. The financial statement is unique:

Table No. 1, showing receipts and expenditures for period from March 30, 1907, to December 31, 1908:

RECEIPTS.	
E. A. Montgomery	\$400,000.00
Bullion receipts	110,505.81
Enterprises	1,455.98
Current accounts payable	26,880.22
Surplus account	1,117.29
Total	\$539,959.30
EXPENDITURES.	
Outlay	\$469,117.93
Operation	61,117.28
Bills receivable	8,707.60
Cash	1,016.49
Total	\$539,959.30

Table No. 2, showing receipts and expenditures for operation for period from June 30, 1908, to December 30, 1908:

RECEIPTS.	
Bullion	\$101,379.54
Enterprises	771.27
Surplus account	1,117.29
Total	\$103,268.10
EXPENDITURES.	
Operation	\$ 53,533.45
Profits earned	49,734.65
Total	\$103,268.10

This balance sheet is absurd. Montgomery is Schwab's representative. The Skidoo Mines Co. was organized with a capital of \$400,000, which was estimated to be sufficient to put the mine on a dividend basis, but more money was required. A dividend is promised for May 1, 1909. The ore in reserve is given at 49,320 tons, worth \$812,000, not including low-grade stuff.

BOSTON CONSOLIDATED.

A report affording so candid an exposition of the affairs of a copper company, would have been impossible a few years ago. The report of the Boston Consolidated Copper & Gold Mining Co. covers operations for the year ending September 30, 1908; it is unsatisfactory without being discreditable. The lack of a sufficient ore supply prevented the operating of more than four sections of the mill between January and September, when an additional four were put to work. It had been intended to extract the ore from the Porphyry mine by steam-shovels. When the capping was removed, however, it was found that the proportion of valueless iron pyrite in the ore was so large as to prevent a concentration of more than 10 to 1 instead of 18 or 20 to 1, as originally intended. This necessitated temporary abandonment of steam-shovel work for mining by the caving system. The ground was blocked out in squares of 60 ft. to a side, thereby extracting 128,390 tons, for a footage of 22,100 ft., and at the same time increasing the ore available to the extent of about 780,000 tons. The probable extent of orebodies in the Porphyry mine is estimated by Sidney J. Jennings, the consulting engineer to the company, as being 27,889,000 tons with an average content of 1.6%

copper, and worth an additional 7c. per ton for the recoverable value of gold and silver. A further block of 9,550,000 tons is also indicated which will barely pay expenses with copper at 13c. per pound, but will yield a profit with copper at any higher price. Its average copper content is 1.45%. Financial reasons prevented an adequate amount of prospecting in the Sulphide mine, in the southern portion of the property. The variable quality of the ore makes it impossible to estimate with any degree of exactness the amount in reserve, but Mr. Jennings conservatively places it at 72,000 tons of payable ore. The mill crushed 149,650 wet tons of an average value of 1.49% Cu, producing 9935 tons of concentrate. The average of the last three months showed a duty of 8.73 tons per day for each Nissen stamp, which indicates a capacity for the whole mill of 2642 tons per 24 hours. With a heading averaging 1.49% and a tailing of 0.425% the mill-recovery appears as 71.5%; the mean cost for the 8 months was 60c. per ton crushed, but fell to 47.2c. for that month, namely, September. Itemized expenses cannot fairly be given per ton of ore crushed, owing to the diversity of operations: steam-shovel stripping of 411,175 tons cost 17.7c. per ton; mining 26,647 tons by the same method, 56.3c.; underground mining of 128,400 tons in the Porphyry mine, \$1.16; 77,540 tons from the Sulphide mine, \$2.87; milling, 60c. per ton; smelting ore, \$4.15; and general expense 45c. per ton. The total amount realized is \$932,000, leaving the company with a net loss for the year of \$164,000. It is proposed to issue a further £100,000 of capital to clear off this and other liabilities due for construction work, and thus place the company on a sound financial basis, with the advantage that profits from this time forward may be available for dividends.

RIO PLATA MINING CO.

The annual report of this company covers the period of eleven months ending November 30, 1908; it is issued from the New York office, whence the mines in Chihuahua, Mexico, are managed. The sales of bullion and concentrate brought \$315,624 for a cost of \$100,886, leaving a profit at the mine of \$248,609. After paying for all debts on plant and property a balance of \$85,280 remains, together with 34,235 shares of treasury stock. The 25-stamp mill crushed 14,093 tons of ore with an average silver content of 82.4 oz. per ton; 56% of the silver was saved, the remainder going to the tailing pond, where it is stored for future cyanide treatment. An electrically equipped cyanide plant is in course of erection, and was to be ready for work in March. Tests by the general manager, D. W. Shanks, show that 85% of the silver in this tailing should be saved. During the period covered, 1018 ft. of development work have been done in the mine, mostly in ore; but no indications are shown in the report of the tonnage blocked out, the ore reserves, nor of the future prospects of the mine in any way. Consequently the report cannot be considered as anything but unsatisfactory.

NUNDYDROOG.

This is one of the gold mines in the Kolar district of India. The annual report for 1908, issued recently to the shareholders, shows continued prosperity. During the year 87,000 tons of ore was crushed and amalgamated for a yield of 74,851 oz., an average of 17 dwt. 5 gr. per ton. In the cyanide annex 70,804 tons of tailing was treated, giving 6038 oz. gold, equal to 1 dwt. 17 gr. per ton. The total of 80,889 oz. exhibits an increase of 5925 oz. as compared to 1907. The gold was worth £303,807 and the profit on revenue account was £140,592. Dividends were diminished by a fire in the mine, a sum of £12,000 being held for contingencies. In order to smother this fire the pumps were stopped, the workings dammed, and the shafts covered tightly. The mine is now being unwatered and the total damage is assessed at £7000. The ore reserves are estimated at 120,895 tons as compared to 111,640 the year before. The deepest workings are at 2600 ft. Thomas Richards is the superintendent; John Taylor & Sons are the managers.

RECTIFICATION OF NATURAL SULPHUR
WATERS.

Written for the MINING AND SCIENTIFIC PRESS
By F. H. MASON.

In many parts of California are hot sulphur springs, so called because they contain varying proportions of sulphuretted hydrogen, the obnoxious smell of which makes the sulphur-content of the water evident. If it were possible to use these waters for irrigation, their value in arid districts would be enormous, for the flow is often considerable, and there appears to be a fair degree of certainty as to the depth at which they may be found in the districts in which they occur. Unfortunately, up to now, attempts to use these springs for irrigating purposes do not seem to have met with great success. At the Hotel el Paso de Robles the grounds are watered with sulphur-water straight from the earth; the water is delivered from a sprinkler and at a good force, said to be 45 lb. per square inch; under this pressure the spray is thrown so far that by the time it reaches the ground it has acquired a temperature approaching that of the surrounding air, and has lost a large proportion of its sulphuretted hydrogen. The result, though vastly superior to the surrounding country that gets no water, would, were it in the neighborhood of a smelter, convince the average jury of twelve farmers that it was a case for heavy damages. The grass is an unhealthy green, with the brown blades far outnumbering the green ones, the prettily grown cypress trees have an unnatural brown tinge, and the vegetation in general has an unhappy appearance.

Speaking from the standpoint of one who has had a fair amount of experience in the adaptation of waters to industrial purposes, I am of the opinion that these sulphur-waters might, in many cases, be made suitable for irrigation by aeration; and further, that by a simple and inexpensive treatment they might be made into better water for household purposes than many that are supplied to small towns in California and elsewhere. Take, for instance, the town of Paso Robles. The main sulphur spring, according to the published analysis, has 101.47 gr. of solids per U. S. gallon, which is, of course, high for a potable water, but, in the absence of analysis, I am inclined to think that the town-water, which is highly calcareous, contains at least an equal amount. In the sulphur-water the solids are principally bicarbonate and chloride of soda; the solids in the town-water, on the other hand, are mainly bicarbonate and sulphate of lime, which are far more objectionable ingredients. Of course, the town-water would be much easier to rectify, and if rectified would be a better water than could be made from the sulphur-water. It could be treated by Clark's process, that is, the addition of sufficient lime-water to convert the soluble bicarbonate into insoluble carbonate of lime, and then removing the latter by decantation or filtration. But the town-water has to be pumped, while the sulphur-water is artesian and will rise to an elevation of 100 ft., which is all that is needed to supply the buildings in the town.

All that would be required, in the way of plant, to treat the sulphur-water would be two large tanks or reservoirs, a small blower, and motive power. The tanks or reservoirs would have to be at a sufficient elevation to deliver water over the area it was desired to irrigate. In the bottom of each tank should be placed a coil of pipe, punctured with numerous pin-holes, and connected with the blower. As soon as a tank had been filled about three quarters full a current of air should be passed through. This would drive out most of the sulphuretted hydrogen, and, if continued long enough, would oxidize the little it does not remove, rendering it innocuous to plant life. Should it be required to further treat the water, filtration through Weldon* mud or wad would undoubtedly convert many sulphur-waters into good drinking and irrigating waters. Filtration through hydrated oxide of manganese, the principal constituent of both Weldon mud and wad, will remove the last traces of sulphur, existing as sulphide, which is the cause of the unpalatableness of sulphur-waters; the sulphur going over to the manganese to form an insoluble sulphide of that metal. The great advantage of these substances as desulphurizing agents is that when they become fouled, that is, when the manganese hydrate has been converted into sulphide, they may be revived by passing air through them, or by exposing them to the air. The sulphur thrown out of combination by the oxidation of the sulphide of manganese will be in the free state practically insoluble and inert. The wad or Weldon mud may be kept in use until it contains from 50 to 60% of sulphur, when it may be either sold to the sulphuric acid manufacturer, or the sulphur may be extracted by suitable solvents and converted into roll-sulphur for the market on the spot.

The metals produced in Mexico for exportation are silver, gold, copper, lead, zinc, and antimony. For domestic consumption, and in limited amounts, the country also yields iron, quicksilver, and tin. The statistics for the year 1906-07, which are a close approximation to the truth are:

Gold	892,825 oz.
Silver	57,925,916 oz.
Copper	113,879,646 lb.
Lead	154,323,400 lb.

Zinc ores assaying from 20 to 60% were produced to the amount of 100,000 metric tons. These exports represent an approximate value of \$73,000,000 gold. Only in the yield of silver does Mexico occupy first position among the world's producers. In order to impart an idea which may be easily retained in the memory it may be said that, if the production were uniformly distributed over the entire area of the country, each square kilometre would afford annually about one kilogram of refined silver.

The cubic contents of a cone may be found by multiplying the square of diameter of the base by 0.7854 and the product by the height, and then divide this result by 3.

*Weldon mud is the precipitate formed by adding milk of lime to manganese chloride or sulphate, obtained as a by-product in the manufacture of bleaching powder.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

QUIETING TITLE TO MINING CLAIM—EVIDENCE.

In an action to quiet title to a placer mining claim the evidence showed that the plaintiff had located the claim, marked its boundaries by stakes and monuments, put up and recorded a proper location notice, and then entered upon peaceable possession, thereafter sinking two shafts to bedrock, and that gold was first discovered at a depth of 72 ft.; that there were no other excavations on the claim except a hole a foot or so in depth. This was said to be sufficient prima facie proof to show that at the time such location was made the ground was unappropriated public land of the United States, its mineral character being admitted, although the proof also showed that there were other stakes and location notices within the limits of the plaintiff's claim, which were not shown to belong to the defendant; but this alone could not affect the plaintiff's title, as a discovery was essential to a valid prior location.

Cook v. Klonos, 164 Fed., 529, Oct. '08.

GAS AND OIL LEASE—GRANTS AND RESERVATIONS.

The owners of land executed a 20-year oil and gas lease, and thereafter agreed to make a new lease for 10 years from the expiration of the original lease, and on the same terms. Subsequently such land owners executed a deed for the land, reserving to themselves all the oil and gas from the date of the deed to the expiration of the extension of the original lease, and also the right to execute a new lease for 10 years after the expiration of the original, and on the same terms. This reservation made by the land owners was held to be for the purpose of retaining the rights which they had in the lease until the expiration of the original lease, and then to extend the same for 10 years.

Collins v. South Penn Oil Co. (Pa.), 71 Atl., 319, Nov. '08.

CONTRACT TO LEASE OIL LANDS—CONSTRUCTION.

One of the lessees in a lease of oil lands assigned his interest therein, and thereafter bought a fourth interest in certain lands not covered by the original lease; the owner of the leased land then made a written contract with the owner of such one-fourth interest in other lands, in which it was stated that he was part owner in such land, and that when he became owner of the other three-fourths he would extend the original lease to such owner of the one-fourth interest; in consideration thereof the latter promised to surrender a certain interest in the oil produced, as provided by the original lease. In an action on the contract it was held to refer only to the fourth interest in the land purchased and not to the land covered in the original lease.

Collins v. South Penn Oil Co. (Pa.), 71 Atl., 319, Nov. '08.

LEASE OF MINE—TRANSFER.

The lessees of a mine agreed with a certain person to transfer the lease to a corporation to be organized by him, in consideration that he would contribute as capital a certain sum within a certain time, and an additional amount at a later date, such agreement being for the express purpose of raising money to continue the business. In an action to rescind the lease the court decided that the promise of such third person to contribute the amount of money promised was a condition subsequent, the failure to perform which was sufficient to justify a rescission of the transfer of the lease, and that the remedy of the lessor for damages was inadequate.

Schneider v. Miller, 113 N. Y. Supp., 399, Dec. '08.

ENTRY OF MINE FOR DISQUALIFIED PERSON.

The United States Statutes prohibit a qualified person from entering coal lands apparently for himself, but in reality as the agent for a person who is disqualified by reason of having already entered the full quantity permitted by law.

United States v. Keitel, 29 Sup. Ct., 123, Oct. '08.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

THE GAS ENGINE. By Forrest R. Jones. 8vo., pp. 446, Ill., Index. New York. John Wiley & Sons. 1909. Price \$4.

The work in hand is of a sort that gives comfort and satisfaction to an engineer of training. It is not a book for the layman. It presupposes a knowledge of physics and a certain acquaintance with power-problems. The types of motors, large and small, are described, with illustrations. Carburation of air, ignition and control of power and speed, are each given a chapter, the latter being most elaborate. Other points to which chapters are given are lubrication, disposal of exhaust gases, starting and adjusting the motor, setting or timing valves and igniter, and a chapter on troubles which will awaken painful memories in the minds of many sufferers. Instead of leaving the reader with the troubles, Mr. Jones ventures to suggest remedies, thereby recalling the assurance of the usual expert when not confronting the particular crisis. But the suggestions are practical and helpful. In addition, the work discusses in detail the more highly technical side of gas engines, explaining the interpretation of indicator cards, physical properties of gases, combination and heat values, theoretical heat-cycles, and so forth. It is a most useful and instructive book.

CLAYS: THEIR OCCURRENCE, PROPERTIES, AND USES. By Heinrich Ries. 2d Ed., 8vo., pp. 554, Ill., Index. New York. John Wiley & Sons. 1909. Price \$5.

This admirable treatise has become a standard which no technical man can omit from his library. Whether one be specifically interested in clay or not, the book is so full of geologic fact, brought out in the elucidation of the occurrence and formation of clays, that it becomes pertinent for a wide range of professional readers. The new edition has been enlarged by additions to the chapters on occurrence, properties, and geographic distribution.

Santa Cruz folio of the U. S. Geologic Atlas. No. 163 of the series. Descriptive text, 3 maps and 2 illustration sheets. Obtainable for 25c. from the U. S. G. S., Washington, D. C.

Catalogues Received.

THE WESTINGHOUSE ELECTRIC & MFG. CO., Pittsburg, has recently issued circulars No. 1160 and 1164, the former on tungsten lamps and the latter on mill motors.

THE FOOS GAS ENGINE CO., Springfield, Ohio, has just published an attractive catalogue on horizontal engines. The pamphlet is replete with illustrations and is interesting reading.

THE NELSON VALVE CO., Philadelphia, has just issued its 1909 catalogue, a cloth-bound volume of 220 pages, which is a valuable addition to any library of trade publications. The company will send it free to anyone interested.

THE LUDLOW-SAYLOR WIRE CO., St. Louis, Mo., has just issued its 1909 catalogue, describing its line of steel, brass, copper, and bronze wire cloth. It contains complete information about and prices of the different styles of wire cloth made by this company. Several pages of conversion of metric to English units and for the comparison of different wire gauges, make the catalogue valuable as a handbook for engineers.

THE PELTON WATER WHEEL CO., San Francisco, has just issued the 1909 edition of its catalogue, which is a handsome volume of 116 pages, illustrated in color. Because of the interest attaching to this branch of engineering, which has recently become an exact science, and which is so admirably described in this publication, the book should be in the hands of everyone interested in hydraulics or water-power supply, because of the information it contains on the measurement of water, loss of head due to friction, horse-power of falling water, and the like.

MINING AND METALLURGICAL PATENTS.

APPARATUS FOR TREATING ORE.—No. 914,002. Frederick E. Woodbury, Milwaukee, Wisconsin, and Benjamin Harris and Centennial H. Benedict, Lake Linden, Michigan.

In apparatus for treating ores the combination with a crusher and a concentrator, of an intermediate classifying jig comprising a screen and means for producing pulsations of water through the screen and provided with a plurality of discharges above the screen, including a slimes discharge and a discharge for material requiring further treatment, and with means for restricting the volume of water passing out with the slimes, a conduit leading from the discharge for material requiring further treatment to the concentrator, and a conduit from the crusher to the classifying jig, substantially as described.

ROCK-DRILL.—No. 913,928. John A. Traylor, Denver, Colorado.

In a rock-drill, a casing, a cylinder, a hammer piston cylinder, and a hammer piston reciprocally mounted in said cylinder, a chuck chamber in said casing, a chuck reciprocally mounted in said chuck chamber, a drill bit secured to said chuck in position to be struck by said hammer piston and arranged in operative drilling relation to rock, a valve chest and a valve operatively connected to said cylinder and chuck chamber, means whereby a supply of actuating fluid is conveyed to said hammer piston and said chuck to move said drill bit and hold it by the pressure of said actuating fluid against the rock being drilled until struck by said hammer piston.

ROCK-DRILL.—No. 914,215. Thomas E. Adams, Cleveland, Ohio.

In a drill, the combination with a drill barrel having an annular series of pockets in its forward portion, and a reciprocating drill rod located centrally in said barrel and projecting forwardly beyond the same, of a series of springs located in the annular series of pockets and projecting forwardly beyond the same for propelling the drill rod forwardly, and a plate or head on the drill rod beyond the barrel, to receive the force of said springs to propel the drill rod, means for withdrawing the drill rod to store the energy of the springs, and means for releasing the withdrawing means at the rear end of the throw of the latter, from the drill rod.

ROCK-DRILL.—No. 913,932. Thomas E. Adams, Cleveland, Ohio.

In a drill, the combination with a drill rod and a propelling spring therefor, of means movable in the same direction as the forward throw of the drill rod to compress said spring, devices for connecting said means with the drill rod after the spring has been compressed for moving the drill rod and compressed spring rearward during the return movement of said means, and trip devices for releasing the drill rod to the action of the propelling spring.

GRIP MECHANISM FOR CABLE-TRAMWAYS. No. 913,775. Rugeley D. Seymour, Denver, Colorado.

In mechanism of the class described, the combination of a suitable frame, two gripping jaws mounted opposite each other and adapted to engage each other, mechanism engaging one of said jaws capable of being swung to two different positions for the purpose of moving said jaw between open and closed position of the jaws, and yielding spring mechanism connected to the other jaw whereby said jaw may automatically adjust itself to varying sizes of rope.

CUPOLA CAR-DUMPING MECHANISM.—No. 911,725. James Hyslop, Harvey, Illinois.

In a device of the class described in combination with a tiltable platform and a track for a car thereon a rigid hook pivotally mounted at one side of the track adapted to detachably engage a portion of the car for the purpose of securing it upon the track and guard flanges inside of and adjacent to each rail adapted to engage the flanges of the wheels of the car for the purpose of holding it upon the track.

PROCESS OF DETINNING.—No. 915,029. Franz von Kugelgen and George O. Seward, Holcombs Rock, Virginia.

The recovery of tin from tin scrap by treating the latter in a closed vessel with dry chlorine to form stannic chloride, controlling the temperature to keep it high enough to effect complete detinning but low enough to prevent attacking the iron and to condense within the vessel such of the stannic chloride as is vaporized, and draining the liquid stannic chloride from the residue of iron scrap within the vessel.

Methods of Testing Electric Detonators.

Written for the MINING AND SCIENTIFIC PRESS
By WILLIAM W. NICOLL.

Those who use electric detonators in firing blasts will be interested in a new electrical testing instrument known as the 'Blasters' Friend', recently devised by the New York Blasting Supply Co. of New York. Owing to the necessarily delicate construction of the platinum wire bridge in the shell of a detonator, it frequently happens that it becomes broken or disconnected; thus destroying the circuit and rendering the detonator worthless. In many cases, misfires and premature explosions are caused by defective detonators. Heretofore, to detect the deficiencies of a detonator before using has been an impossibility, owing to the absence of a testing instrument adapted to the purpose.

The component parts of the new device consist of an extremely sensitive chloride of silver battery, to which are connected two separate solenoids, which are carefully tuned with the ignition wire in the detonator. The outside of

the instrument contains two metal posts, which when connected produce a magnetic flux actuating a small piece of metal attached to a staff, to which is affixed the designating vane, or as it is termed, the 'O. K.' disc. The outside poles, when connected, cause the current to flow through the wires and platinum bridge of the detonator, energizing the solenoid which actuates the staff carrying the designating vane and causing the 'O. K.' disc to come to a common centre. The face of the disc, upon which is stamped 'O. K.' shows through a glass dial in the side of the instrument, thus designating that the circuit is complete. When the wires are withdrawn from the instrument, the vane or disc disappears from view. The operation of testing a detonator is extremely simple; place the end of each wire on the poles of the tester, and if the 'O. K.' disc appears it is perfect; if the disc fails to appear, the detonator is defective. To test the entire blasting circuit: after all holes are loaded, connected, and the leading wires attached, before connecting the blasting machine or electric current, place the end of each leading wire on the poles of the tester, and if the 'O. K.' disc appears the entire circuit is complete; if the disc fails to appear there is either a ground, broken wire, or poor connection requiring adjustment before the blast can be fired.

From the above description of the 'Blasters' Friend' and the explanation of its use, its importance as a part of the equipment for blasting is apparent. The instrument is mounted in a case, which is substantial, and covered with black leather; the dial-glass is surrounded and retained by a lacquered brass retaining-ring, about the size of a watch crystal, locked from the inside. The instrument can be carried in the hip or side-pocket without inconvenience, ready for instant use.

Screening in Utah Copper Co.'s Mill.

As originally designed and equipped the mill of the Utah Copper Co. contained trommels as the main screening equipment, the undersize passing over stationary inclined screens. Each of the twelve units comprised four 48 by 144 in. trommels, and two inclined flat screens, the trommels being

clothed with rolled-slot wire-cloth, equivalent to about No. 6 mesh, and the stationary screens with similar material passing a product equal to about No. 20 mesh. Shortly after the first units were placed in commission the usual difficulties in the operation of trommels became apparent, and more efficient and economical equipment was sought. A number of devices were tried on a working scale. The results were so favorable to the impact-screen that it was determined to equip the twelfth unit, at that time nearing completion, with these screens, and to demonstrate conclusively in it the adaptability of the machine for the work. The twelfth unit was operated with improved results, due to closer sizing, and with a capacity of 600 as against 500 tons per day, owing to the tables being able to handle a greater tonnage of the more closely sized feed. The screens in this unit were running wet. The work of replacing all the screens throughout the other units of the mill was then determined upon, and has proceeded as rapidly as possible without undue interference with operations. Sufficient time having now elapsed to permit of comparison between the two, the net result of the change can be summarized as follows: The capacity of each unit has been increased from 500 to 600 tons per day, the tables handling the increased feed by reason of the closer sizing. There has been effected a saving of about one-fourth of the water formerly used by the trommels because of running the four coarse impact-screens, the crushing rolls, and the elevator on the ore dry as it comes from the mine without the addition of water. This also increases the life of the elevator from 4 to 18 months. The cost of screen-cloth is in the ratio of \$128 for the trommels, to \$14 for the impact-screens. The impact-screens were made by the Colorado Iron Works of Denver, Colorado.

Commercial Paragraphs.

THE DENVER FIRE CLAY Co., Denver, has recently published a bulletin describing a new crucible which, it is claimed, is a distinct improvement on other designs. The bulletin will be sent to anyone interested.

THE MOORE & SCOTT IRON WORKS, San Francisco, has purchased the shipyard at Oakland, Cal., belonging to Boole & Sons. The consideration is said to be nearly half a million dollars. The new owners will enlarge the capacity of the plant and will build a dry-dock of 5000 tons capacity.

WM. AINSWORTH & SONS, Denver, announce that they have recently received orders for analytical balances with Ainsworth multiple rider carrier from the U. S. Food Inspection Laboratory, Denver; the U. S. Mint, San Francisco; and the Watertown Arsenal, Watertown, Massachusetts.

THE GENERAL ENGINEERING Co., Salt Lake City, Utah, has added a contracting department, and has entered the field as contractor for the erection of milling plants and the installation of the necessary machinery. This company's ore-testing establishment continues an important adjunct to the business.

The Wall Street Journal of March 17, 1909, contains an article reviewing the affairs of the WESTERN ELECTRIC Co. for the first quarter of the fiscal year 1909, in which it is shown that the business of this concern for the period stated amounted to 30% more than for the same period in 1908, while the increase in the number of customers was 40%. The company is operating at about 70% of its capacity.

THE BEHREND DRY CONCENTRATOR Co., of 10 Wall St., New York, recently installed a test plant, under their system, for Senator A. B. Lewis, in Salt Lake City, Utah. The plant was completed in February of this year, and began operation on lead-zinc ore of a complex nature, containing sulphides of lead, zinc, iron; carbonate of lead and silicate of zinc; in a quartz-baryta gangue. This ore occurs at Pioche, Nevada. The tests were successful and proved beyond doubt the applicability of this system of dry concentration to these ores, and its commercial utility for making products of high value at a low cost. Mr. Lewis has decided to install a Behrend dry concentrating plant of large capacity on one of his properties at Pioche, Nevada.

EDITORIAL.

IT IS PROPOSED in Texas to enact a mining code following the Mexican rather than our national plan. Texas, by reason of having retained control of its public lands when admitted to the Union, is in a position to adopt the code which best applies to local conditions.

IT IS pleasing to announce that Mr. R. M. Raymond, after distinguished services in the upbuilding of the great operations of the El Oro Mining & Railway Company, has become managing director of the enterprise, and will henceforth reside in Mexico City. The duties of personal supervision of the property will devolve upon Mr. Alfred F. Main, who has been promoted to the position of general manager, which is a proper reward for long and able service.

THE STRIKE at the Broken Hill Proprietary mine is being conducted with much vigor and many picturesque accompaniments. Tom Mann, one of the leaders, being forbidden to make speeches in the district, has retreated to Melbourne, from which point of vantage he dispatches gramophones with canned eloquence to his followers. What arrangements are made to provide proper gestures, we are not informed, but if need be the cameraphone will doubtless be pressed into service.

NEVADA is not yet depleted of its rich ore. During the week we were informed concerning 160 pounds of ore from near Winnemucca that realized \$10,000 at the Selby smelter; of the total value \$7500 was in the form of 'metallies' or native metal collected on the laboratory sieve. But pounds of ore are not as impressive as tons of it; we hear that the Goldfield Consolidated shipped 6 earloads, or nearly 200 tons, that averaged 30 ounces of gold or \$600 per ton; nine more earloads are on the way.

COLOMBIA keeps to the fore. Mr. F. Lynwood Garrison contributes another illuminating article to this week's issue, following the line of practical suggestions for travel and comfort in that country to which we had previously devoted space. Attention was called recently to the re-division of Colombia into smaller Departments or gubernatorial units, for the purpose of more efficient administration. The map accompanying Mr. Garrison's article shows the latest subdivisions of the Republic, and also exhibits the railroads now open.

IT HAS been determined that dredging costs bear an inverse ratio to the bucket-capacities. From the figures given in another column it is seen that a deduction was made of the equivalent cost of a five cubic foot dredge working in normal gravel. Applying the figures to eight and thirteen foot buckets re-

spectively it will appear from the costs given that the expenses in those cases should be 3.5 and 2.15 cents. These are actually the costs of dredging with buckets of those sizes by one of the leading companies of California.

A COMMITTEE of the Gold and Platinum Miners' Association of Russia has been investigating the possibility of substitutes for platinum, a question of great moment to them, and it reports that there is little likelihood of a substitute being found to take the place of platinum in most of its commercial uses. The only exception is the increasing use in chemistry of vessels made of fused quartz crystal. On the other hand, attention is called to several new uses for which platinum is fitted by its high melting-point and its resistance to chemicals.

OUR NEW YORK contemporary, having once placed the Mount Morgan, reputed to be the greatest gold mine in the world, in New Zealand, and having later credited it to New South Wales, has at last placed it in 'Central Queensland.' The *Queensland Government Journal* complains of this disinclination to credit the mine to its home State, and cites the declaration of a reputed visitor, speaking before one of the Institutes, to the effect that it was necessary to "leave Queensland on the late afternoon express" in order to reach the mine. The objection is natural, and in the interest of peace we hope the mine will be left hereafter where planted by nature.

WHETHER COPPER production or copper consumption will be in excess at any particular time is a matter of unfailing interest. The mines now open and being opened are undoubtedly capable of greatly increased production. It is much harder to make estimates of future consumption. As bearing on the problem, it is of interest to note that the American Telephone & Telegraph Company used over a million miles more copper wire in 1908 than in 1907. This is the report of only one consumer, but any one familiar with the extensions of telephones and electric traction systems now under way cannot doubt that the future will show not only a growth in copper consumption with increase in population, but a larger per capita consumption as well.

THE EAST AND WEST lines of the C., M. & St. P. railroad were connected last week near Missoula, Montana, and without fuss or ceremony a new trans-continental line came into being. The contrast between the quiet completion of this railway and the military and civil display which accompanied the driving of the golden spike on Promontory Point, marks the distance we have traveled since the Union and Central Pacific roads were completed. That was a great national achievement, binding together the East and the West, forestalling a possible new sectionalism. With the greater development of our resources and our growth in solidarity, the completion of our sixth transcontinental line becomes but a bit of the day's work. On the checker-board of business it is possible, however, that this building into the Northwest of a great rail-

way, tributary neither to Hill nor to Harriman, may prove as potent as did, in our political history, the building of the overland route.

OIL discoveries continue to be heralded from central Nevada. They are easily made: When a drill-hole is lost, and pending the order for another equipment, a couple of barrels of oil are emptied into the hole and shortly afterward eager speculators arrive on the ground. As the water has risen, the oil also is near the surface, so that a bottle lowered at the end of a string brings up an encouraging sample. But Nevada is not the only region of wonderful discoveries, we are informed that in the desert (why is the desert such an incubator of yarns?) of southern California, within a mile of a railroad, there has been found a deposit covering 20 acres, of vaseline. Assuredly the modesty of the acreage affords convincing proof of the truth of the story, for any fabricator would not be content with a beggarly 20 acres; why not 200? This deposit is so soft that the observer sank to his knees in it, but he emerged, otherwise this had never been written. More proof!

APPLICATION for an extension of the receivership of Milliken Brothers, made before Judge George C. Holt of the United States District Court for the Southern District of New York, brings out the fact that the recent cut in steel prices has actually not stimulated industrial activity; on the contrary, conditions are worse than at any time since June 1907, at which time this concern went into a receivership. Naturally a mere reduction in the price of a great commodity which is practically controlled by a single corporation cannot restore confidence and promote new enterprise. As we pointed out some weeks ago, guarantees of prices for a definite period are essential, otherwise no contractor can venture to assume obligations, and development of new business is checked. The present policy of the Steel Trust is harmful to the entire nation. Incidentally it is driving the independents to the wall. The American Bridge Company is taking contracts at prices said to involve actual losses. All this tends inevitably toward absorption of the small producer. It is being accomplished at high cost, most of which falls upon the people at large.

PROGRESS is being made in the organization of the Instituto Mexicano de Minas y Metalurgia. At a meeting held in Mexico City on March 25 committees on membership, organization, finance, and meetings and proceedings reported. A general committee is now at work correlating these reports. The membership of this committee, including R. E. Chism, H. S. Denny, G. H. Garrey, E. P. Merrill, J. J. Reynoso, and Kirby Thomas, assures a successful outcome. It is too soon to say what form of organization will be adopted, but it seems that the plan of the American Institute of Mining Engineers will be closely followed. Provision for meetings of local sections is, however, to be made. That there has been a real need for this in the United States is shown by the success of the local sections of the Mining and

Metallurgical Society. It would seem at least doubtful whether in Mexico there is as yet the same opportunity to develop vigorous local bodies without throwing membership open to all comers. In this connection it may be noted that the proposed by-laws really leave the choice of membership largely in the hands of the council. This is perhaps a necessary temporary expedient, but is nevertheless dangerous. Centralized control makes for prompt success but is apt to discourage healthy individual activity. We hope the new society may escape all pitfalls and become a strong associate of the American and Canadian institutes.

The Mexican Outlook.

In Mexico there is one party; it is called the party of re-election. It has been said that in Mexico there is no public opinion; in Venezuela there is active public opinion, which has recently been expressed with peculiar emphasis. This shows the difference between two kinds of rulers. Castro was a dictator and so is Diaz, but one was a shameless tyrant, and the other is a beneficent guardian of the welfare of his people. Venezuela, with ruined credit, found herself driven to ridiculous dependence on fine-spun legal technicalities and shifty diplomacy to keep foreign nations from making justifiable reprisals; Mexico enters the financial markets of the world and freely borrows money for the greatest irrigation plan ever projected by any government, and her national railway merger bonds are oversubscribed. Venezuela was a steady defaulter; Mexico, April 1, promptly retired \$10,000,000 of short-time gold notes issued by the National Railroad. President Diaz assumed the reins and proved himself capable of driving the coach of state; now his people insist upon retaining him in power.

In spite of this, the fact can not be blinked that opposition to the modern Cid Campeador exists in Mexico. The aspirations of Gen. Bernardo Reyes are well known. Younger men also look with longing toward Chapultepec. Circumstances might well arise which would embarrass the even course of administration, necessitating a show of force that would for a period restrain the influx of foreign capital needed for developing the resources of the Republic. In view of this, the failure of President Diaz to establish the government firmly in the hands of others while he himself is able to stand sponsor for the continuance of peace would be unfortunate. Perhaps he intends more than is generally known; the succession may be accomplished by means of resignation after the next election. That would insure a long tenure of the new incumbent without the risk of disturbing competition by opposing candidates for office.

The annual message to Congress was presented on April 1. In this President Diaz gives a picture of national progress and prosperity in the face of the business depression that demonstrates great financial vitality. The rate of interest has steadily declined during the year, manufactures are increasing, and the railway earnings denote a revival of activity. It is also pointed out that the increased quantity of

exports compensated the shrinkage in market value of the commodities. At the same time the imports declined to such an extent as to throw the trade-balance strongly in favor of Mexico. The mining industry, however, has suffered severely from the troubled state of the metal market. The Government undertook to facilitate the resuscitation of the Cananea mines and smelter by conceding free entry for fuel-oil, and the result was so beneficial that the policy of encouraging the mineral industry by concessions permitting economical production is being extended.

Railroad development within the last six months has been important, bringing the United States into communication with Mazatlán by the prolongation of the Southern Pacific branch southward from Navajoa. The road from Guadalajara westward has reached Tequila, and in the north the line from Nogales is now completed to Del Rio. The length of the Federal railways is 11,825 miles, to which must be added 5007 miles of State lines, bringing the total to 14,832 miles. The President might have called attention to the fact of increasing development of mines, which has been conspicuous in Chihuahua and Jalisco. Capitalists have been taking advantage of the financial depression to purchase good properties on the 'bargain counter'. Recent activity in this direction has been remarkable. At the same time, rapid progress in the installation of hydro-electric power-plants has been an important feature. There has also been a growing demand for lands by colonists, and plans for exploiting enormous timbered areas in western Chihuahua and Durango have been made by persons supposed to represent Standard Oil interests. Manifestly capital is not fearful of political difficulties in Mexico. In spite of diatribes against the President and his administration, which find inconsiderate publishers and hysterical readers in this country, the men who have most to gain or lose are demonstrating in no uncertain manner their faith that dangers do not threaten the Republic which has been wrought by the wise statesmanship of Porfirio Diaz.

Eight Hour Legislation.

Under guise of police legislation the social revolution, so widely heralded, has made advance in several Western States. The example of Utah in limiting a day's labor in mines and around smelters, reduction works, and refineries, to eight hours, by a law enacted in 1896, was followed in 1903 by Nevada, and this year by California. The Nevada statute has been supplemented by legislation just enacted to include open-cut mining also. The stamp of approval was set upon the Utah statute by the United States Supreme Court in the case of *Holden v. Hardy* (169 U. S., 366), in 1897. This was carried up on a writ of error, and the right of the State Legislature to protect the health of the people was fully sustained. The exceptional nature of employment in mining and smelting was affirmed, the contention being that dust and gases present in both occupations exposed the operatives to unusual peril, and that lessening the hours of labor served a purpose bene-

ficial to the public by reducing the time of exposure to these influences. Conceding the utility of this restriction, it follows, and was so held by the Court, that no class legislation was involved in the discrimination between the operations of mining and metallurgy and other forms of industry. The decision maintained that inequality exists between employers and operatives, resulting in compulsion from which the laborer could not escape without undue hardship and financial loss, and that the enactment of legislation to protect him from unnecessary exposure to health was in the interest of the welfare of the State. The right of contract was held to be unimpaired by the drastic provisions of the law, which made it a misdemeanor for anyone to be employed under any agreement or pretext for a greater consecutive period than eight hours in the situations mentioned. The State is, accordingly, acknowledged to possess the power of restricting the acts of individuals when such curtailment of liberty is in the interest of the public.

It will be seen that the only evasion possible is to contract for piece-work. This could be done either by individuals, or by an association of persons, who would perform the work under contract by their own unaided labor. The legal restriction is upon the employment of operatives, not upon labor itself. Actually the restriction becomes general because of the impossibility of conducting extensive operations without the hiring of laborers, and furthermore because the labor unions have placed the ban on contracts. It must be observed that the Supreme Court, in *Holden v. Hardy*, distinctly reserves its opinion on the constitutionality of State statutes restricting hours of labor in general, where no question of health and safety was involved.

The Utah statute was devised to apply the eight-hour principle under cover of police regulation. It was so well done that it passed review by the highest tribunal in the land, in consequence of which other States may follow in the same course without fear of reversal. The Nevada statute was upheld in the State Court, and presumably that was considered final, as no appeal was taken to the United States Supreme Court, and there seems to be no doubt that the constitutionality of the California law would likewise be sustained. The action of the Nevada Legislature this year in extending the restriction to open-cut mining has passed beyond the ground confirmed by the Supreme Court, raising a question to be determined through further litigation. The real purport of the legislation stands clearly revealed. The doctrine is emerging from underground to assert itself broadly in the open air. It is, in effect, a part of the great social revolution of the age. We do not deery it: the body politic can not stand still while momentous industrial changes are taking place. The evolution of industry in one detail necessitates maintaining the equilibrium by changes in another.

There must be compensations; if shorter hours are demanded the pay must be measured according to the service. There are many mines in California capable of paying fair wages and reasonable profit when operated on the old standards, that must close if the labor unions insist upon the nine-hour wage

for an eight-hour day. The law says nothing as to what the laborer shall receive, but it has precluded the miner from working longer than eight hours per diem. If he finds less work to do he will have to obey the law of supply and demand and reduce his price, or else he must secure the repeal of the statute. We would be glad to feel that reason will prevail, and that local unions will take cognizance of local conditions in adjusting the scale of wages, bearing in mind that the principle of charging 'all the traffic will bear' spells ruin to industry.

The Supreme Court in its findings has by implication affirmed, furthermore, that the laborer has a right to his job; that he is in the weaker position, and hence that the law may extend a shield over him and insure his tenure as against the necessity of grappling with the alternatives of prejudicing health by injurious employment or of abandoning his position. The old doctrine, rudely expressed in the phrase 'if you don't like the work, move on,' is denied by the terms of the decision which has validated this form of the eight-hour movement. This is a step in advance of the great Teacher of the broader socialism who said, "Is it not lawful for me to do what I will with mine own?" Apparently not. The authority of the Supreme Court is unquestionable, and it is interesting to see how the thought of its learned judges is molded by the tendencies of the epoch. We confess inability to follow the reasoning which attributes to mining and metallurgic work such exceptional unhealthfulness. Personally, we do not believe that the peril of silicosis in a gold mine is greater than the danger of infection by many diseases from the street-dust we complacently tolerate in our cities; we would prefer the risk of the miner to that of the motorman or city teamster. The dust of the smelter is no more dangerous than that of a cement mill; if we must discriminate along such lines the time-honored lustiness of the blacksmith may be regarded as a poetic myth. The gases of a smelter, to be sure, are dangerous, especially when they contain lead or arsenic, as they usually do, and there is reason for insisting on protective measures. Not only may hours of labor in such places properly be reduced to a minimum, with wages sustained on a level commensurate with the danger, but more exacting requirements for eliminating gases than is now customary might come within the purview of the law. Frankly, we do not believe that the eight-hour laws as applied to mining and metallurgic works in general are justified by any exceptional danger to health involved. If such were the purpose of this legislation it should not sweepingly include all classes of reduction works, as has been done in Utah, Nevada, and California. No one can pretend that a stamp-mill is an unhealthier place in which to labor than a machine-shop, a brick-yard, or a flour-mill. The odds may easily be the other way. Beneath the technicalities the essentially discriminative character of the legislation is plainly visible to straight-thinking men. The real question is a shorter day's labor for the workingman, but it were wiser to fight it out fairly on its merits, or else to construct police regulations operating equitably on a basis not limited to single industries.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

J. W. MERCER is at Denver.

F. L. BOSQUI is at Madrid, Spain.

RAYMOND A. LINTON was in San Francisco.

JOSEPH H. SHOCKLEY of New York is in the city.

H. L. SWAIN, of Mexico City, is here on a visit.

W. B. WINSTON has gone to Shasta county, California.

A. C. LANE has been lecturing at Wisconsin University.

F. A. LEACH, Director of the Mint, is in San Francisco.

C. S. HERZIG expects to go from Nicaragua to Montana in May.

G. H. GARREY has been examining mines near Mapamí, Durango.

C. W. HAYES and DAVID T. DAY are in Mexico examining oilfields.

JUAN FELIX BRANDES has returned to London from Mexico and Colorado.

ERNEST V. ORFORD is general manager of the De Lamar mine in Idaho.

FALCON JOSLIN is in New York. He will soon return to Fairbanks, Alaska.

F. P. MILLS is the new manager of the Giroux copper mines at Ely, Nevada.

C. BARING HORWOOD is manager of the North Randfontein mine, near Johannesburg.

S. F. SHAW has moved his office from Pasadena to 821 Central Bdg., Los Angeles.

BAILEY WILLIS, of the U. S. Geological Survey, is lecturing at the University of Chicago.

S. A. DOCKERY is with the Mazapil Copper Co., at Concepcion del Oro, Zacatecas, Mexico.

FRANK JENKINS has become assistant manager of the El Oro Mining & Railway Company.

G. C. KLUG has been appointed manager of the Great Fingall mine, in Western Australia.

RICHARD HAMILTON has been elected president of the Australasian Institute of Mining Engineers.

CARLOS W. VAN LAW has closed an engagement with the Guggenheims, and has moved to New York.

ALFRED F. MAIN succeeds R. M. RAYMOND as general manager of the El Oro Mining & Railway Company.

WILLIS LAWRENCE is superintendent for the Sierra Morena Mining & Refining Co., at Paso Robles, California.

GODFREY DOVETON has completed testing the mills of the Guanajuato Development Co., and has returned to Mexico City.

FRANK GOODMAN has resigned from the Ohio Copper Co. to become general manager for the Montreal Co. in Wisconsin.

H. E. WEST is returning to El Oro, Mexico, having accepted an appointment with the El Oro Mining & Railway Company.

FRANK W. OLDFIELD was in San Francisco after an extended trip through Jalisco and Chihuahua. He has gone to Tuolumne county, California.

R. M. RAYMOND has resigned as general manager of the El Oro Mining & Railway Co., to become managing director, with residence in the City of Mexico.

J. W. WOODFORD, during the past four years superintendent for the Princeton M. & M. Co., of Dolomi, Alaska, has become general superintendent for the Iron Mountain Tunnel Co., at Superior, Montana.

J. H. VAN AMRINGE of Columbia University was the recipient of a loving-cup from the alumni of the School of Mines on April 3, the occasion being the anniversary of his birth, and at the close of a half-century of teaching.

General Mining News.

ARIZONA.

GILA COUNTY.

At the Eureka property, which was recently merged with the Globe Consolidated, preparations are being made to sink a shaft. A good deal of preliminary work, such as road building and grading has been done. The Eureka adjoins the Miami on the south and is believed to carry the same character of ore. There is also a strong vein of carbonate and oxide ore which has been opened to a depth of 40 ft. The Cordova Copper Co., which is the name of the re-organized Globe Consolidated, has made preparations to sink the Gem shaft 400 ft. deeper, which will give it a depth of nearly 1600 ft., or about the same as the thirteenth level of the Old Dominion. A 3½-ft. vein of sulphide ore has recently been struck on the 1200-ft. level, which assays 6% copper, 38% iron, and 40% sulphur.—The Old Dominion is maintaining its output around 3,000,000 lb. per month while the price of copper remains below 13c. About 150 men have been laid off. Pumping in the mine has been largely increased by the unusually abundant spring freshets, and the five million gallons taken out per day may be utilized later for concentrating plants.

PINAL COUNTY.

The gold discovery announced two weeks ago as having been made by J. H. Bates and A. Sears turns out to be an

electric two-drum hoist with a capacity of 2000 ft. The new compressor will soon be in place and several machine-drills will be used. Mark B. Kerr is superintendent.—At a depth of 440 ft. an 18-in. shoot of good-grade ore has been encountered in the Montana mine in Willow valley. The vein is supposed to be a continuation of the rich shoot formerly worked in the old levels. W. G. Brown is superintendent.—The new mill at the Giant King mine is rapidly nearing completion. Considerable development work is under way and a large reserve of milling ore has been opened.—The pumps at the Lecompton are again in action. The mine has been idle since last January. Samuel Colt is superintendent.—It is reported that the Morning Star and Badger Hill mines in the Cherokee district will be shortly re-opened and operated on a comprehensive scale. A number of properties in this district, including the well known Siberian, are attracting attention.—Considerable placer mining is going on at various points as a result of the heavy rains of the past winter. Many old hydraulic mining towns, such as North Bloomfield and North San Juan, eloquently testify to the former importance of the placers in Nevada county, now almost a memory of the past.

Grass Valley, April 12.

A 7-ft. vein carrying gold has been found at Chicago Park during development by the Golden State Mining Co. Two feet on the hanging wall side is oxidized, free-milling, and plentifully sprinkled with gold. The remainder is not so valuable, containing, however, abundant sulphide. George A. Shebley, the principal owner and manager, has a 4-stamp mill operated by water-power. The discovery was made through an upper adit, but another about 200 ft. lower down is now in 300 ft., and will be advanced forthwith to intersect the new vein.—The strike made by E. H. Wilson in the Sixteen-to-One mine near Alleghany, nor far from the famous Tightner, is the most important of some months in the vicinity. It is stated that since April 1 no less than \$20,000 has been extracted.—The Nichols mine, a mile west of Grass Valley, is to be re-opened by the California Exploration Co., a new company, organized under the laws of Arizona. Oscar Coffin, F. D. Mitchell, and G. H. Hellman are representatives of the company now engaged in examining the property.

PLACER COUNTY.

Twenty men are working at the Jupiter mine. The richness of the channel, like all others, varies in value, but so far not a barren spot has been found. A crew is at work opening the Big Dipper lead, where Mr. Rose, the superintendent, has found good gravel.—The site for the new compressor at the Annie Laurie has been prepared, and the compressor itself has arrived. Two carloads of other material are at Weimar awaiting shipment to the mine. The shaft on the Annie Laurie is 32 ft. deep, and carries gold at every point developed.

SAN BERNARDINO COUNTY.

(Special Correspondence).—At a called meeting of the stockholders, held in this city on April 6, the officers of the Orange Blossom Mines & Milling Co. resigned, and new officers were elected. It has been decided to re-organize the company and endeavor to place it on a profitable producing basis. It is said that the new mill is a failure and that the property has been badly managed. The stock formerly sold at par, but is now down to 7c. It is estimated that 50,000 tons of \$6 ore are in sight and with slight alterations to the mill can be treated for \$3 per ton.—Conditions at the Orange Blossom Annex are far from satisfactory. The vein swerved from the shaft at the 60-ft. point and it will be necessary to run a cross-cut from the shaft in an endeavor to find it. Only three men are now employed.—Negotiations are under way for the sale of the Yellow Aster mine at Randsburg to a New York syndicate. It is understood that

North Bloomfield.

excellent one. The exact locality is 7 miles north of the old Peter Winkelman ranch, now known as the town-site of London, and immediately north of the property of the London-Arizona Mining Co. The vein is between 9 and 10 ft. wide, and extends through 10 claims.

YAVAPAI COUNTY.

Bert Thorne and H. L. Sweeney are developing a group of claims in Grapevine canyon, Black Hills. They have over 1000 ft. of work done on this group, and are now drifting on their Golden Gate claim. The ore is copper, showing gold and silver.

CALIFORNIA.

NEVADA COUNTY.

(Special Correspondence). One of the richest strikes made in this district for many months has been recorded at the Central Consolidated mine at Banner Mt. A strong vein of milling ore has been opened up, and this vein is traversed by a narrow streak of high-grade. The ore resembles that in the Idaho-Maryland. The company is arranging to push more extensive developments. Twenty stamps are dropping at present. C. N. Bailey is superintendent.—It has been decided to run four drifts, two east and two west, from the bottom of the 1100-ft. shaft at the Pittsburg mine. An order has been placed with the Taylor Foundry & Engineering Co. for the early delivery of an

the consideration is \$1,500,000. The property is held under an option by Albert Anchor.—At the Exchequer considerable milling ore is being broken and the mill is running continuously.—Considerable mining is going on in the Silver Lake district and several rich strikes are reported. This district was much in evidence two years ago, but the financial stringency caused a practical suspension of activities. Recently several companies have resumed work on the most promising mines and prospects.

San Bernardino, April 9.

Forty miles south of Needles and half a mile from the Colorado river, A. S. Munn has taken up 76 claims, on which there is said to be abundant nitrate of potash. If this be true the deposit should be of considerable importance.

SHASTA COUNTY.

The dredge belonging to the Shasta Dredging Co. has progressed so far that the hull is now ready for launching. Contrary to custom, the hull has been built on solid ground, instead of in a pit. Forty men are at work, and 200,000 ft.

of lumber have been utilized. The Yuba Construction Co. is doing the work under contract, for the price of \$120,000.—The Clipper and Croesus mining groups were transferred last week from Alfonso di Nola and Henry J. Wicker to the Carnegie Mines Co. for a consideration of \$140,000. The purchasing company was incorporated in California March 16, with a capital of \$2,000,000. George H. Cross, of San Francisco, is president of the company, and Alfonso di Nola is vice-president.

The Mammoth plant of the U. S. Smelting, Refining & Mining Co. at Kennett is now operating to full capacity, treating a tonnage of 1700 tons of ore daily. This company now has a payroll of 1000 men. It is planning an additional expenditure of \$50,000 upon its smelter, in widening its crane track and other improvements.

TUOLUMNE COUNTY.

From the rich strike recently made in the App mine at Quartz over \$50,000 was extracted in a few days. The extent of the orebody is not yet known. The ore is yellowish gray in color.—It is probable that an Eastern company will secure control of the Floyd mines, which are owned by J. L. Gibbs, of Tuolumne.—The New Aurum Mining Co., of which L. D. Rogers, of Los Angeles, is general manager, is increasing the crew employed at its mines on Hunter creek, and this week started up the mill. A car

load of rails has been purchased and will be used in constructing tracks from the Hunter and War Eagle claims to the mill.—The True Business and Horse Shoe mines, situated on Knight's creek, and owned by Senator J. B. Curtin and others, have been bonded to H. W. Gendar and H. M. Wetherbee.—One hundred men are employed at the mines in the vicinity of Soulsbyville—50 at the Soulsby, 30 at the Black Oak, and 20 at the Draper.

COLORADO.

CLEAR CREEK COUNTY.

Two feet of solid galena were uncovered last week in a stope on the sixth level of the Mineral Chief. Tests show 55% lead and from 60 to 70 oz. silver per ton. There is also exposed a body of milling ore that is about four feet wide. The aerial tramway has been brought into use in delivering the product to the 50-ton mill. The compressor plant recently purchased was put into commission last week, and machine drills are now being used. C. E. Pughe, the manager, expects to complete the raise from the sixth to the fifth level within 30 or 40 days.—The Alice Gold Mining Co. has a force of men at work extending drifts in the big dike of the Alice mine. Work on the 300-ton milling plant will be put under way as soon as weather conditions permit. A. H. Roller of Idaho Springs is manager.—Grading is in progress for a transformer house at the Gold Hammer mines on Donaldson Mtn. Temple electric drills have been ordered and are to be installed without delay. B. J. Martelon is manager.—T. I. Slater, manager of the Gold Anchor mine and mill at Alice, is unwatering the mine workings, and during the next ten days the new mill will be started on its second run.—The Michaelson system of ore-dressing is to be installed at the Gold Dirt mine, owned by the Empire T. Co. It is understood that the company controlling the Michaelson patents has made an offer for a 10-year lease upon the property and that a 200-ton plant will be erected.

LAKE COUNTY.

The Grand View vein, which was struck last week in the Granite tunnel, is found to be about 10 ft. wide, and to assay \$15 per ton. Near the hanging wall is a small streak which carries several ounces of gold per ton. Arrangements are being made to install a new air-compressor.

SAN JUAN COUNTY.

The Crown Point Mining, Milling & Power Co., under the management of George C. Franklin, is pushing work both in the mine and mill at the Suffolk property near Ophir. Thirty men are now employed, one-half in the mill, and the remainder underground. It is intended to put up 40 stamps, and 20 of these are almost in place. Pipe-lines, the flume, and the Huson tramway are also being put in shape, and Franklin hopes to have the whole in operation some time in May.—Concentrates have been accumulating around Silverton owing to the snowstorms. Shipments have now been made to the extent of 7175 tons, of which the Gold King shipped about 5000, and the Hercules 1025. No crude ore has yet been sent out, but this month it will add to the shipments of concentrate to the Durango smelter.—The Animas Power Co. went into the hands of receivers some time ago with an indebtedness of \$1,350,000. The Standard Trust Co. of New York held the trust deed against the company's property and effected a sale of its affairs. The holding was bid in by a re-organization committee.

SUMMIT COUNTY.

The Wellington mill at Wellington is now completed and is said to be successfully treating ore from the mine of the same name. It was built by J. J. Seaman.—The new Reiling dredge has started work in French gulch below the Reliance dredge. It is operated under the general management of H. J. Reiling, and is superintended by F. Z. Hunt.

UTER COUNTY.

At the directors meeting of the Portland Gold Mining Co. the regular quarterly dividend was declared, but at the rate of 3c. instead of 4, as formerly. The reduction is said to be for the purpose of holding a reserve for mill construction. By next meeting the directors will have decided on

capacity of the plant to be installed. The Clancy process will be used, thereby obviating roasting.—Union Leasing Co. has beaten its record by shipping 97 carloads of ore during the month of March. This is an exceptional production for the company, and is due to an accumulation, as is shown by the fact that there are only 65 miners on the company's payroll.

IDAHO.

IDAHO COUNTY.

Richard A. Kleseattle, manager of the Black Diamond Mining Co., operating at Dixie, announces that a 10-stamp mill will be erected on the property the coming summer. The company has been running a 4-stamp mill since October. In the meantime developments have proved so satisfactory that it was decided to increase the mill capacity.—At least a dozen placer mines will be working this summer in central Idaho, and numbers of owners have effected improvements. The Golden Rule has had its volume of water greatly increased by enlarging the new 8-mile ditch. The Cook brothers have put in new flumes along the ditch that supplies their Gold Hill placer. Buffalo Hill, owned by Butte men, with J. M. Anderson as manager, has bought an elevator, which will be installed early in the summer. Pete Erickson has made some improvements to his equipment on Little Elk. At Newsome the Leggett Creek Co. is adding hydraulic machinery, as is also the Donforth property in Dixie.

SHOSHONE COUNTY.

Development on the La Blanche property on Pine creek has been started, and a contract for a 1500-ft. adit has been let to McDermott & Batterton of Kellogg. This will give a depth of 1000 ft. below the upper workings. There is some talk of equipping the mine with machinery, but no action has yet been taken.—The trouble which the Missoula Copper Co. has been having with its diamond-drill prospecting now appears to be about ended, and an advance is being made of 15 to 30 ft. per day. In the first hole a heavy water flow up to 170-lb. pressure was tapped. This is diminishing, but the flow in the other hole is increasing. The heavy pressure of water prevented securing a core, but the cuttings assayed 1.6% copper.—A contract for 100 ft. has been let to John Page on the Liberty group of claims in the Lookout district. This will tap the vein at a depth of about 50 ft., when drifting will be commenced.—A small force of men has been set to work clearing out the workings of the Stewart mine at Wardner. It is believed that this is the first step toward a resumption of development. F. Augustus Heinze, the principal owner, is expected to visit the mine during the present month and in the meantime a detailed report will probably be made on the workings by one of Heinze's engineers.—The Bunker Hill & Sullivan Co. has declared a dividend of \$60,000 for the month of April. This is a reduction of \$15,000 on the regular dividend, due to the low price ruling in the lead market. The company has now paid out \$10,986,000 to date.—A report states that fully 7½ ft. of shipping silver-lead ore has been exposed in the shaft being sunk in the Josephine mine. Good ore is also showing in the upper workings. The shaft is down about 105 ft. Work has been resumed at the tailing plant of the Mitchell Concentrating Co. in Wallace. For some time past a series of experiments have been conducted, and it is believed that the plant has now been put in good condition. Work has been started with twoammers and five tables. It is believed that a profit of about \$120 can be made per 24 hours.

Twenty men will be set to work on the Paragon Consolidated property to continue the lower drift, and at the same time to drive a 600-ft. raise from the No. 3 level. The question of erecting a mill has been under consideration, but no action will be taken yet. The No. 1 ore shoot has been encountered in the property of the Hennessey-Burns mine at Burke. The depth was between 70 and 80 ft., and 2½ ft. of quartz and galena have been exposed. The men have now been set to drive for the No. 2 lode, which is about 100 ft. ahead. Announcement is made that a 2-compartment shaft 400 ft. deep will be sunk on the

Butte & Coeur d'Alene Mining Co.'s property near Mullan. The shaft has been equipped with an electric hoist and compressor plant, which will be in operation as soon as connection can be made with the wires of the Washington Water Power Co. James E. Quinlan is president of the mining company.—The Caledonia mine near Wardner, has entered the list of shipping properties. A carload of ore has been prepared which will run from 8 to 40% lead and 100 oz. silver. Twenty-four men are at work on the property. A shaft to be sunk to the 500-ft. level is now down 450 feet.

MICHIGAN.

Last year the Tamarack Mining Co. milled 654,900 tons of 'rock' at its 5-head stamp-mill. There was a decrease in the yield of refined copper, amounting to 1.2 lb. per ton stamped. This was chiefly owing to treating a larger tonnage of low-grade ore from the developments on the Osceola amygdaloid. Recently some of the richest 'rock' ever disclosed in the mine was broken in the breast of the eighteenth level in No. 3 shaft, and still continues good.

MONTANA.

BEAVERHEAD COUNTY.

Certain ground in the neighborhood of Argenta is considered to be of value for placer work, and L. D. Tibbets, of Argenta, states that drilling machinery has been ordered for testing its value.

MISSOULA COUNTY.

The big cyanide plant, which was ordered some time ago for the French Bar Mining Co. operating a group of claims close to the Idaho boundary, has now been delivered at the property and is being installed under the supervision of John Lacasse. Henry Kuphal has been appointed chief engineer, and will survey the different veins of ore recently opened up in the mine.

SILVER BOW COUNTY.

The Butte Coalition Co. is gradually increasing its output, and the new levels in the Minnie Healey and Rarus mines are opening well, a lot of new ground being developed. The output now averages about 1400 tons of ore per day. The company at present is engaged in running a cross-cut from the Rarus 1700-ft. level to the Tramway shaft, and connections will be made before the Tramway station is cut. The 1600-ft. level in the Minnie Healey is just getting into the orebodies, but stoping is only being done on the 1400 and 1500-ft. levels. The cross-cut from the Rarus to the Tramway shaft will be completed within the next three weeks. The new levels of the Tramway are the 1700 and 2000-foot.

NEVADA.

CLARK COUNTY.

The Empire Gold Dredging Co. of Los Angeles has bought a Lidgerwood bucket dredge with a daily capacity of 1000 cubic yards, to operate 300 acres at Las Vegas Wash, on the Colorado river. The company also owns a lot of dredging ground at Laguna Dam, in Yuma county, Arizona. H. J. Meyer, the secretary, says the gravel runs from 15 to 50c. per cubic yard, with an average of 25c., and estimates his costs at 6½c. The company's other officers are A. B. Call, J. R. McDonald, and D. F. Doggett.

ESMERALDA COUNTY.

The ore output of the mines and leases of Goldfield district for the past week amounted to 6930 tons, valued at \$507,850, and was the second largest yield in the history of the camp.—Forgeries of Florence company stock on an extensive scale have just been brought to light by the receipt for transfer at the company's office of a certificate for 2500 shares, which officials of the company pronounce to be spurious. The certificate is printed on an exact duplicate of the stock certificates of the Florence company, and purports to have been issued to Arthur W. Bikker, Jr., at present living at Redwood, California. A bungling forgery of the signature of T. G. Lockhart is a striking feature of the spurious certificate, but the seal is also a poor imitation of the official one. Another feature is that where the genuine

certificates are punched with a safety check showing the number of shares for which they are issued, a rubber stamp is used on the forgeries.—The Consolidated company announces a new strike of ore 10 ft. wide and averaging \$100 per ton in the Lucky Boy claim of the Jumbo, south of the Red Top. It has been opened up for 20 ft. Bullion to the value of \$200,000 was shipped out by the Consolidated during three days or the same amount as was shipped during the last three days of last week.

The Orleans mine, also known as the Cottrell, at Horn-silver, is making good progress in the development of high-grade ore. The vein is 14 ft. wide, but so far the shaft has not been sunk more than about 60 ft.; however, a 25-hp. Fairbanks-Morse hoist is now about to be installed, and sinking continued to the 100-ft. point. Shipments of 200 tons have been made, and were paid for by the Nevada Reduction works at the rate of \$127 per ton.—The Lucky Boy mine at Hawthorne is also doing well. The principal owners are John Miller and J. K. Adams, but most of the ore is being taken out by lessees, under the management of J. D. Hubbard. The shaft is nearly 400 ft. deep, and developments have been carried about 300 ft. in each direction in silver lead ore worth \$100 per ton.

HUMBOLDT COUNTY.

(Special Correspondence).—Samuel P. Harris, representative of the London syndicate which is constructing the mill in Seven Troughs, has arrived here and will remain until the plant is completed. D. H. Skae, the manager, believes he will have it ready in two weeks. The scale of charges is graduated from a minimum charge of \$5 per ton.—The Fairview mine sent out a shipment of ore to the smelters instead of sending it to the local mills, on account of the high proportion of silver. It averages about \$200 per ton.—The Wihuja lessees on the Seven Troughs Coalition have sunk their incline shaft 375 ft., and are getting out excellent milling ore from a shoot in the Kindergarten vein. The heads average \$65, which will be reduced by adding low-grade ore from the dump. The Merger lessees, working on the same property, have ordered a hoist and are about to sink a hundred feet. The Jess-Bard and Sandifer lessees, also on Coalition ground, have effected a consolidation, in order to obtain mutual advantages with respect to pumping.—Work has been resumed on the Potter-Arnett lease on the Mazuma Hills by the installation of a 50-hp. engine and a No. 7 Cameron pump. The engine will be run by steam, the first in the district, and a shaft will be sunk 300 ft. before any lateral work is done. The Mazuma Hills and Reagan veins will then be explored.—At the Farrell end of the district there is considerable activity. The Snowsquall has got free-milling ore on hand to send to the new mill; the Rico mine has developed three new veins; and on the Hero Nevada they are running an adit under the Hillside shaft where they have got into a 10-in. streak of shipping ore.—The Caesar tunnel is now in 150 ft. After 750 ft. have been done three veins will have been cut, the showings of which on the surface are distinctly valuable. Just below the Caesar, the Three Wills Co. has also opened three veins, and the middle one assays \$70 per ton. A shaft will be sunk on this middle one to develop them all. Mazuma, April 12.

NYE COUNTY.

The total output of the Tonopah mines for the past week was 5841 tons, of an estimated value (the shipping ore being valued at \$60 a ton and the milling ore at \$25 a ton) of \$146,025. The Tonopah company sent 3150 tons, the Belmont 950, the Montana-Tonopah 961, the Midway 200, and the MacNamara 300 tons.—The Tonopah Mining Co. broke 457 ft. of new ground during the week, and lowered the 3-compartment Mizpah shaft down to 1323 ft. The bottom of this shaft shows no change, being still in dacite.—At the Belmont all repairs on the surface have been completed, and everything is ready for churn-drilling from the 1000-ft. level.

WHITE PINE COUNTY.

The Nevada United Mines Co., which now has control of the old Martin White mine at Ward, 18 miles south of Ely,

has a big tonnage of ore blocked out that will sample 15% lead and 15 oz. per ton in silver, and running high in iron. The men in control of the company are Franklin Guiterman, H. B. Northrup, Walter G. Boyle, J. B. Grant, W. O. Temple, and J. A. Snedaker, all of Colorado. It is reported that this company is trying to persuade the Nevada Northern to extend its line from Ely to Ward. Mr. Guiterman and Mr. Grant are closely associated with the smelting interests of the Guggenheims in Colorado, and the latter dominate the affairs of the smelter and railroad at Ely.—The Amalgamated Nevada Mines Co., whose interests are in charge of J. H. Marriott, of Osceola, has had 12 men employed during the past winter on the San Pedro and Mabel properties at Black Horse, 9 miles northeast of Osceola. The company has placer holdings on Dry creek, at Osceola, which are under lease to miners who have been tunneling and drifting in the gravel beds all winter, piling up placer dirt to be washed with the freshet of water that comes with spring weather. The Amalgamated company is also employing a few men on Baker creek, laying a pipe-line to carry water to operate an electric generator.—The St. Lawrence mine, in Snake range, 18 miles south of Osceola, has employed 6 men during the winter, developing a body of lead ore, much of which samples 40 to 60% lead and 40 oz. silver per ton. F. C. Williams is manager, Orson Hudson being in charge of the work. It is opened by an adit that has been driven 400 ft. on the vein. By extending it farther a depth of 300 ft. will be gained, as the mountain at this place rises abruptly to that height. It is planned to erect an aerial tramway from this mine to the valley below, requiring a line 2 miles long.—J. H. Marriott has partly developed a tungsten mine in Wheeler's Peak, 8 miles south of Osceola. The tungsten ore occurs in a vein between granite walls, the white quartz gangue carrying 8 to 10% tungsten. His plan is to put up a small plant for concentrating the ore.—The Veteran shaft of the Cumberland Ely has a double-drum electric hoist, operated by a 300-hp. motor, running 400 r. p. m. The winding speed of the hoist is 500 ft. per minute., and it is now operating two 5-ton skips to a depth of 480 ft. The latter are loaded and dumped automatically. The shaft is 8 by 24 ft., with two compartments for skips and one for a cage to carry the men. The cage is operated by a steam hoist.

During March the Nevada Consolidated and the Cumberland-Ely shipped 3,805,259 lb. of copper, of which the former company produced nearly 60%. The total amount shipped by both companies since the beginning of the year is 8,618,969 pounds.

NEW MEXICO.

SOCORRO COUNTY.

The Mogollon Gold & Copper Co. has been re-organized and, it is said, will soon resume operations on a large scale. The new officers of the company are: Frederick M. Seward, of Goshen, New York, president; W. H. Royce, of Middletown, New York, vice-president; and Frank P. Jones, of Silver City, treasurer.—A large amount of machinery is being hauled out to the gold camps of the Mogollon Mtn., and the copper camps of the Burro mountains.

GRANT COUNTY.

For the first time in over a year there is plenty of water for placer mining in the Pinos Altos district. About 100 men are at work washing dirt, averaging from \$3 to \$4 per yard.

OREGON.

BAKER COUNTY.

Thomas Lammers and D. K. Evans, of Spokane, who recently inspected the Cougar property near Sumpter, are arranging for a resumption of operations. The dredging company owns several hundred acres of placer ground along Powder river, below Sumpter.

UTAH.

JEAR COUNTY.

The Opex Mining Co. has extensive holdings in the neighborhood of the Centennial-Eureka, Grand Central, and

Mammoth mines, the stockholders therein being Jesse Knight, F. A. Heinze, Samuel Newhouse, F. P. Swindler, and others. As the initial step in thoroughly exploring and prospecting this territory at the necessary depth, the company, under Swindler's direction, has sunk a 3-compartment shaft to a depth of 2000 ft., and this sinking is to continue 500 ft. deeper. Each compartment is 4 by 4½ ft., two for cages and the third for a man-way. The shaft is timbered in the best fashion and stations have been cut at 1000, 1300, 1500, and 2000 ft. The hoisting is done with a 14 by 20 double-drum hoist, of Hendrie & Bolthoff make, a special steel 1-in. cable being used. In the 28 days of February 186 ft. of sinking was done. Swindler states that the cost of sinking the 200 ft. has averaged \$45 per foot; that the cost of powder used has averaged \$3.49 per foot. The cost of equipment and the installation of same amounts to \$30,000.

The directors of the May Day Mining Co. have been elected for the ensuing financial year, and include John Dern, W. S. McCornick, James Chipman, M. P. Braffet, and M. S. Nielson. During the year ending March 31 the company sold 5218 tons of ore for \$89,192, 1768 tons of concentrate for \$44,027, and paid out \$44,000 in dividends.—The Schwab Mining Co. will operate the Agnes, East Point, and New Idea claims in the eastern end of the Tintic district. The officers of the company are Samuel Schwab, John Roundy, and S. Brockbank.—The Zuma Mining Co. has raised enough money to continue its development of six claims in East Tintic. Electric power has been obtained from the Telluride Power Co., and there is ample equipment at the mine. C. F. Kratzer, of Wallace, Idaho. W. S. Garity, and Rasmus Nelson are the principal owners.

SALT LAKE COUNTY.

The new silver-lead orebody on the 700-ft. level of the Day mine of the Nevada-Utah Co. is now proved for a width of 130 ft. without reaching the wall. This orebody has been opened to 20 ft. above the 600-ft. level and it is just as good grade as where first encountered on the 700-ft. It has also been cut on the 800-ft. level. Most of this ore assays 20 to 40 oz. silver and 10 to 15% lead.—The Utah Consolidated Copper Co. treated 248,200 tons of sulphide ore at the Garfield smelter in 1908, yielding 10,648,200 lb. copper, 265,284 oz. silver, and 23,440 oz. gold. The company's smelter at Murray is to be dismantled, and shipments will be made to Tooele when the contract with the Garfield Smelting Co. comes to an end in April 1910.

WASHINGTON.

FERRY COUNTY.

Development is progressing at the First Thought mine near Orient, where P. Burns owns 80% of the property. E. E. Alexander, of Spokane, who recently inspected the mine, says the orebody is 120 ft. wide at the surface, while at the 300-ft. level it is 500 ft. wide. Thirty-five men are employed, and a yearly tonnage of 14,000 has been shipped over three miles of aerial tram to the Great Northern railway to Northport and other smelters.

The Phoenix Gold & Copper Mining & Milling Co. is operating on a group of seven claims on Cecil D. Mtn. An immense vein traverses three claims the full length of 4500 ft. From a number of samples taken the ore assays from 3 to 15% copper and from \$2 to \$10 gold per ton. One shaft is down 80 ft. and another is down 20 ft., and there are also several open-cuts. George Ilse of Spokane is the president and general manager and Geo. B. Dean is superintendent.

OKANOGAN COUNTY.

The Peerless Mining Co. has driven an adit into Little Mount Chopaca over 400 ft., the last 60 ft. having penetrated an orebody which assays in gold, silver, and copper up to about \$80 per ton, and contains traces of platinum.—The Nighthawk mill has made a satisfactory three days run with 10 stamps, and the full battery of 20 stamps is now in operation, but it is uncertain if it can be kept running continuously on the limited quantity of ore blocked out.—The Free Gold mine, idle for ten years, has been acquired by the Owasco, a new Eastern company. It is situated on the

Similkameen river, west of Oroville. A 10-stamp mill goes with the mine. A new manager has arrived, and steam will be replaced by electric power. The mine was formerly a good producer of gold ore.

STEVENS COUNTY.

Operations will soon be resumed at the Globe mine, on Toulon Mtn. An aerial tramway is under consideration, to convey the ore three miles, to the Spokane Falls & Northern railway at Orient.—The machinery has been repaired and new buildings have been erected and work will shortly be resumed on the Jay Gould mine, under the management of the Travelers Mining Co. F. C. Bailey of Chewelah is superintendent.—An adit has been driven on the Tungsten King mine, near Deer Park, which has tapped a vein from which 1000 lb. of wolframite was extracted in one day.

CANADA.

BRITISH COLUMBIA.

The Donald Copper Co. is steadily developing the Bruce group, three miles west of Midway. Two shifts under the direction of J. D. Graham have driven 380 ft. of adit, and also a considerable amount of surface work, developing what is considered a promising body of copper-bearing ore. It averages 5% copper and carries \$6 per ton in gold. These claims were taken over last July from S. M. Johnson and J. C. Haas, the latter of whom has been retained to superintend the operations of the company. J. H. Tilsley is president.—A mill is being erected at the Jewell mine to try out a new method of separating gold from the tailing. It is an invention of H. G. Nichols, manager of the Ymir mine, and the Slimes Treating Co. has been formed to promote its use.

ONTARIO.

Official figures show that the ore shipped from Cobalt in 1908 contained 19,394,496 oz., valued at \$9,112,746, and the by-products of cobalt and arsenic brought the total value for 1908 up to \$9,229,768. The Gowganda and Montreal river silver camps are detracting attention from Cobalt, although almost nothing has yet been done there. Yet in the Cobalt district thousands of acres of mineralized land in Coleman and Lorrain townships have not even been prospected. Cobalt Central has 777 acres, all mineralized. Of this big acreage, only four acres have as yet been developed in two years operation. Nipissing has 840 acres, of which less than 20 acres have been opened up after five years work. La Rose is working in only one corner of its big acreage. The same is true of all the companies with extensive holdings.

MEXICO.

COAHUILA.

R. U. Atkins, representing the Mexican Coal & Coke Co., has announced that the company has found a fine seam of coal 8 ft. 8 in. thick in the No. 8 shaft at Las Esperanzas. The coal is of excellent coking quality. E. R. Jones and E. Ludlow are the managers.

GUERRERO.

Many pertenencias have recently been denounced in the neighborhood of Placeres del Oro. Fred McFarlane, of Portland, is reported to be bringing in a 20-stamp mill for treating a good vein he owns eight miles northwest of Placeres. The Fortuna mine has been sold to R. Buchanan and L. W. Stover, who have taken up other claims round about. An *antigua* in the Rio Frio country has been cleaned out by J. M. Barry. It has obviously not been worked for a long time, but assays of the vein have shown that it is worth development.

SONORA.

The Greene Cananea Copper Co. turned out an even 2000 tons of copper during the month of March, together with 89,000 oz. silver and 520 oz. gold. At the present time a considerable amount of betterment and improvement work is going on at the property, a part of which is charged to the cost of production and the balance to construction account. In all, it is estimated that the expense of the improvement work going on is equal to 1c. per pound of copper now being produced.

Special Correspondence.

LONDON.

Rio Tinto Decreased Profits.—United Alkali Finances.—Broken Hill Proprietary.—Palmarejo.—Dolcoath.

The report of the Rio Tinto Co. for 1908, which has just made its appearance, contains information of special interest. The drop in the price of copper has affected both profits and dividends. The profit for the year was £1,230,133 and the dividends £1,108,437; the rate on the ordinary shares being 55%. Two years ago the profits were approximately double that amount, and the dividend 110%. Another point of interest is the increase in local output of copper. A few years ago additional smelting plant was provided, but owing to continued drought it could not be operated. This trouble is now past and the results are seen in increased production. The copper produced during the year by treatment at the mines amounted to 24,256 tons, as compared with 21,251 in 1907. For the last 20 years the production at the mines has remained about 21,000 tons annually, so that last year's figures exhibit a notable in-

reduced the profits of this great undertaking. Once more the ordinary shareholders have to go without a dividend. The net profit was £362,244, out of which £133,746 was distributed as debenture-interest and £187,878 went to the 7% preference shares.

Current history of the Broken Hill Proprietary is followed closely here. Cabled reports just to hand give results for the half year ending November 30 last, and show a none too brilliant condition. The output was 2,926,148 oz. of fine silver, and 47,842 tons of pig lead, for which the average prices obtained were 25.86d. per oz. and £12 per ton, respectively. The profit was £25,791, which, as the directors say, cannot be considered adequate to the capital. Not only has the margin of profit been reduced, but the cost of improvements, additions, and replacements has had to be provided by drawing on the reserve fund to the extent of nearly £80,000. In addition to all these worries the directors are troubled with lack of success in developing ore-bodies. They report that explorations on the lower levels have not added appreciably to the ore reserves. June 1, 1908, the ore reserves were estimated at approximately three million tons. During the half year 264,847 tons were extracted. If no further orebodies be found, the life of the mine at this rate will be little more than 5 years. As the shares, which have a nominal value of 8s., stand at 30s., it is evident that the troubles of the company are considered by many to be temporary.

The Palmarejo mine in the State of Chihuahua, Mexico, has been worked for over a hundred years, and in the early days the rich silver sulphides gave handsome profits by pan-amalgamation. When these ores were exhausted the deposits ceased to be of value. The mine was bought at a fabulous price by an English company 23 years ago. The history of this company during the first 15 years is not pleasing. Mr. Southcott finally undertook to re-organize and put it on a paying basis, with T. H. Oxnam as engineer. The pans were 'scrapped', and a cyanide plant substituted. However, the metallurgical difficulties still continued and losses were so great as to wipe out

Dust Storm at Broken Hill.

crease. In addition to this output, the copper content of 589,815 tons of pyrite exported, was 9958 tons, bringing the total for the year to 34,214 tons as compared with 32,317 in 1907. Less cupriferous pyrite is now exported and more is treated on the spot. The export of sulphur ore or barren pyrite has, however, continued to increase, being 668,477 tons in 1908, as compared with 619,814 in 1907, and 477,843 in 1906. A third item of importance is that large sums of money are being spent in improving the methods of mining. Extensive work is being conducted with the object of mining by open cast, and eventually the costs will be considerably reduced. At the present low price of copper it has been impossible to meet this expenditure out of incomes; accordingly the money has been provided by borrowing on the security of the reserve fund. The balance sheet states that the "Investment in Consols and other securities deposited against advances" is £623,350. The item of 'Creditors' has also increased by over £500,000 during the year. These figures show how immense are the financial resources of the company to permit of such extensive re-organizations during years of depression.

The United Alkali Co. owns extensive pyrite mines in the south of Spain not far from Rio Tinto. Formerly the company bought pyrite from the Rio Tinto, the Tharsis, and other producers. Only within the last few years was the policy of owning mines adopted. The company reports that the mines now supply a large proportion of the pyrite required and that recent development has proved the existence of additional orebodies. Increase in cost of raw material, especially of fuel, together with the fall in the price of copper, and the bad general condition of trade, have

profits. Eventually the mill was closed and Edward T. McCarthy was commissioned to report on the property. Knowing that the ore was much the same as that treated with profit at Tonopah and in several parts of Mexico, Mr. McCarthy visited these districts before going to Palmarejo, to obtain the latest metallurgical information. On arriving at Palmarejo he found the ore to contain an average of 15 oz. silver and 1½ dwt. gold, and that it was amenable to the treatment recommended. He obtained extractions of 88% of the silver and 93½% of the gold, in an experimental plant rigged for the purpose. This should be compared with an extraction of 62% in the old cyanide plant. The costs in the modern plant would be less than in the old cyanide plant. Mr. McCarthy found one and a half million tons of readily available ore. His recommendation is that a 40-stamp mill be erected, with tube-mills, agitators, and filters, having a capacity of 260 to 300 tons per day. He also recommends improvements in power, water-supply, and transport, and he estimates that £116,000 will be required. The directors and shareholders are willingly subscribing this money.

Great interest has been centred on the Dolcoath mine during the last few weeks owing to the continued development of rich ore at depth. At the recent meeting of shareholders the matter was discussed at some length, and among others Richard Pearce contributed some valuable observations. Briefly, the increase in richness and the discoveries of new orebodies have taken place at about 3000 ft. in the portion of the mine where the new vertical shaft is to cut the lode and meet the workings at present served by the old inclined shaft. Mr. Pearce, who was connected

with this mine 60 years ago and has followed its fortunes ever since, is of the opinion that the new ore-shoots are only the apex of more extensive deposits. The company issued a special circular this week describing the exact position of the latest find, which runs a hundredweight of black tin per ton, as compared with the average of 40 lb. Naturally, when anything good turns up in the mine, it is somebody's business to exaggerate. In this case one of the London papers announced that rich copper-tin ores had been found in excavating for some new workmen's cottages, but this turned out to be a fable. The directors of Dolcoath feel that they were justified in sinking the new shaft, a policy which at the time of its inauguration had not a few captious critics. These, or similar gratuitous advisors, are now finding an outlet for their energy by joining the controversy as to whether the pumps which will be put in when the new shaft is completed shall be Cornish pumps or electric pumps.

SALT LAKE, UTAH.

Silver King Smelter. — International Smelter Plant. — Utah Con. Profits. — Boston Con. Output. — Bingham Mines. — Western Utah Copper. — Pioche Mines.

When it was announced a few days ago that F. Augustus Heinze was negotiating with the International Smelting Co. for the sale of the ore-contact which he had with the Silver King Coalition Mines Co., it was made known at once that officials of the mining company would not consent to such a transfer. Silver King officials claim that when Heinze secured this contract, it was with the distinct understanding that he would build and operate a smelter in Utah. Holders of large interests in the Silver King subscribed for stock and agreed to give financial backing to the proposed smelter which was to enter into direct competition with the A. S. & R. and the U. S. Smelt., Min. & Ref. companies. Agents for Heinze claim that no such stipulation is in the contract and that they can dispose of it at will. The Silver King is shipping 100 tons of high-grade silver-lead ore to the American furnaces at Murray, having an average assay value of \$60 to \$65 per ton. The mine has been the largest silver-lead producer in Utah for a number of years. It has paid dividends in excess of \$11,000,000 and is making quarterly distributions of 15c. per share, aggregating \$187,500. The contract with Heinze calls for the delivery of ore to him for a period of 10 years beginning January 1, 1909. In compliance with this agreement the company began delivering ore to Heinze's agents about January 10. Heinze had, in the meantime, leased the Milford smelter and he had announced that the ore would be shipped to the furnaces in southern Utah, but as soon as the ore was received he consigned it to the A. S. & R. Co. The mine officials claim that they have given Heinze ample time to begin building his smelter; that they have been lenient in view of the fact that he was badly crippled in the financial depression. Unless he concludes to build the smelter, they announce their intention of forming an independent smelting company and embarking in the custom ore business. The contract now in force calls for a treatment-charge of \$14 per ton, and metallurgists claim that this \$8 ore can be treated at a profit. The contract would be worth several million dollars to Heinze, and the International company is supposed to have offered him more than \$1,000,000 for the transfer.

The International Smelting & Refining Co. has let the contract for the excavation for the foundation of its smelting plant in Pine canyon. This work will require the removal of over 100,000 cu. ft. of earth. The contract for the steel structural work has already been let, and J. A. Dunlap is in Chicago to arrange for the equipment. The railway spur will be completed to the plant by May 1. It is said that the Salt Lake Copper Co., a Lewisohn concern, which has representation on the board, will ship its copper product to the International. This, in addition to the Utah Con., and with several silver-lead mines forwarding ore to the International, will make it an active competitor for

custom ores in Utah. The Utah Copper Co. has at the present time two shovels on ore in pit A; one on waste in each of the following contours, C, E, G, H, and two in F. A ninth shovel will be put to work directly on ore, and a tenth is now on the way.

The annual report of the Utah Consolidated Mining Co. shows that it has made a net profit during 1908 of \$326,312. During this period it has produced 10,648,243 lb. copper, 265,284 oz. silver, and 23,440 gold. The property is producing 800 tons of copper ore daily, which is treated at the Garfield smelter. It is now paying quarterly dividends of 50c. per share, and has distributed profits amounting to \$7,836,000.

The Boston Consolidated has increased its output. The mill is producing concentrate carrying 1,000,000 lb. of copper, to which the sulphide mine is adding ore carrying no less than 500,000 lb. per month. On this production it is claimed that the company is more than meeting its operating expenses. The subscription for the new stock amounting to 50,000 shares, will give the management about \$550,000, less a 5% commission. Its indebtedness is now \$450,000, and it will require \$165,000 to pay the cost of removing the overburden to permit steam-shovel mining. The mill has a capacity of 3000 tons, and when the overburden is removed, which will require 4 months time, the company will probably decide to double its mill-capacity.

Experts for the Cole-Ryan syndicate have completed inspecting the Tintic smelter plant and the Colorado mine, belonging to the Knights. The financial condition of the Bingham Mines Co. is gradually improving. A payment of \$97,000 has been made on its first-mortgage bonds, bearing 6% interest, reducing the total amount outstanding from \$903,000 to \$806,000. The mine is now producing 60 tons of silver-lead ore per day. Duncan McVichie has just returned from New York. While in the East he made arrangements for resuming operations at the Western Utah Copper Co. mine in the Clifton section of Deep creek. This company has more than 1,000,000 tons of ore carrying 5% copper. Herman Green is manager, and he will organize a force to begin work at once. The Western Pacific has promised to build a branch line into the camp, work to be inaugurated within a couple of months. There are other producing mines in that district. F. Augustus Heinze is one of the largest shareholders in Western Utah Copper. The Guggenheims have acquired some properties in that mineral belt. Four to five cars of ore per month are being shipped from the Prince Con. mine at Pioche. Murray and Ernest Godbe are now carefully sampling the new orebodies encountered in the lowest workings. James Breen, of Butte, a Heinze smelter man, has recently inspected the camp. He reports a large tonnage blocked out, sufficient to supply a smelter for a number of years. The Godbe syndicate, which controls the Prince, Ohio-Kentucky, and several other properties, are not disposed to make a contract for smelting until they have had an opportunity to test the Fink process further. Both the American and United States smelting plants are badly in need of lead ore. The two are running at about one-half their capacity, the American treating 1000 tons and the United States 700 tons per day. The Tintic Smelting Co. is taking about 1000 tons of lead ore daily which formerly went to these plants.

DENVER, COLORADO.

Degge Case — Craig Placer — Grand Junction. — The Jennie Sample Controversy. — Cripple Creek. — Lead and Zinc Ores.

About a year ago the Wellington Investment Co. obtained much undesirable notoriety through the methods of the promotor, W. W. Degge. The case has re-appeared in court, and a temporary injunction has been granted to the Mining Investor Publishing Co., restraining Degge from making use of the subscription lists of the Mining Investor. It was proved that Degge obtained these by questionable methods. The suit by the company for \$10,000 damages was compromised by the payment of a nominal sum and costs. The Colorado Mines & Water Co., which purchased the Craig

placer from the Blivens Mining Co. early in 1908, has thoroughly tested the ground and worked out the problem of operation. The company has purchased new machinery of larger capacity than that taken over with the property. There are several thousand acres in this district that show gold in a fine gravel free from large boulders. Dredging will be started at once.

The Gibson Lumber Co. and the John F. Rice Lumber Co., both doing business at Grand Junction and Montrose, have been made defendants in a suit brought by the Federal Government to recover \$60,000 worth of timber illegally cut near Montrose. The construction of the High Line canal, which starts near Grand Junction, is now assured. As soon as the local association has deposited its half of the money, the Reclamation Service will begin work on the tunnel through the Palisades. It is expected that condemnation proceedings will need to be resorted to in a few cases where right of way has been denied.

The fight for the control of the Jennie Sample Consolidated Mining Co., will doubtless end in the courts. At the annual stockholders' meeting, held in Cheyenne, two sets of officers were elected. The use of telegraphic proxies was questioned by the Bernard-Burns faction, and the matter was referred to the committee on credentials. It is the action of the credentials-committee in refusing to recognize the telegraphic proxies that will form the basis for legal action. During March the production from Cripple Creek amounted to \$1,382,570. The average value of the ore was \$22.95, which is an increase in value per ton of \$2.50 over that for February. The deep drainage tunnel progressed approximately 1000 ft. during the month. The work is being pushed rapidly at all three headings. A vein carrying \$3.60 in gold was cut 5400 ft. from the portal. This vein is believed to be the one showing on the Earl lode claim on Grouse mountain. The Birdsall lease on the Michigan Gold Mining Co.'s property on Gold hill has been sold to W. S. Rowell and associates. The Wacu Weta lode claim on Bull Cliff, adjoining the Cheyenne of the Isabella Mines Co., is advertised for sale at public auction.

A. B. Lewis has returned from Salt Lake City, where he witnessed a series of experiments made in the treatment of the lead-zinc ores from a mine he is interested in at Pioche, Nevada. The ore was concentrated on a Behrend dry concentrator. The experiment was considered satisfactory and arrangements will be made to erect a Behrend plant at the mine. The ore contains sulphides of lead, zinc, iron, carbonate of lead, and silicate of zinc.

BUTTE, MONTANA.

Pittsburg & Montana.—Production Costs.—Electric Power Development.—Coal Land Decisions.

Report concerning Pittsburg & Montana has it that the Amalgamated Copper Co. is the real interest behind the re-financing of that company, and that the East Butte, Pittsburg & Montana, and South Butte Mining Co. will be found shortly among the Amalgamated assets. The mines of the Pittsburg & Montana, under the management of Oscar Rohn, have been put in excellent condition and have been constantly improving. About 150 tons of first-class ore, and 200 tons of second-class, are mined daily, and even with the present smelter-capacity the production can be greatly increased. However, the smelter is being re-constructed and enlarged, and by the middle of July or the first of August the capacity will be 500 tons per day. The concentrator will be able to handle 250 tons, and will probably be later enlarged to 500 tons capacity. The company owns 287 acres of mineral ground in east Butte, with the extensions of a number of the big veins. In addition to this ground, it owns 600 or more acres near Helena and at Swissmont, including some iron claims and silver-lead properties. When the present management took hold, both the property and the company were in a bad way, following the long, expensive, and barren experiments of Ralph Baggaley with a new smelter process. The new process has been discarded, and the Pitts-mont ore shipped to the Washoe smelter at Anaconda. In

the general curtailment of copper-production in the Butte district in 1907, the Washoe refused to receive any more Pitts-mont ore. The mines were temporarily shut down and Mr. Rohn converted the old plant into an ordinary smelter, of 200-ton capacity. The mines were operated at a profit all through the panic and since. The converter-plant was entirely re-built and standard acid-lined converters erected. A 250-ton concentrating plant was also built during the summer of 1908. The blast-furnace capacity is now being increased by 300 tons. The first-class ore sent to the smelter runs 7% copper, and the second-class, going to the concentrator, assays between 3 and 4%. Most of the mining is done on two orebodies near the east and west ends of the property, about 2000 ft. apart. Between the orebodies the ground is practically unexplored. There are two working shafts, each 1200 ft. deep. From the 1200-ft. level two winzes have been sunk 300 ft., from the bottom of which 600 ft. of cross-cutting was driven several years ago. At present mining is confined chiefly to the 800 and 1000-ft. levels, though some ore comes from the 1200. On the latter level are about six miles of openings, cross-cuts, and drifts.

Butte Mines.

At the west end the 1000 and 800-ft. levels have been connected, and the ore is fully as good on the 1000 as on the 800-ft., the stope being 25 ft. wide. In a cross-cut south on the 800-ft. level, two new veins have been cut, assaying 7% copper; these are 6 ft. wide. On the west end of the 800-ft. level the showing has also improved.

A great electric power-system is being developed in Montana. In a few years not only the principal mining companies but the railroads will use electric power. The Chicago, Milwaukee & Puget Sound road has already contracted for power for the operation of its trains, and a few days ago officials of the Northern Pacific and representatives of the Madison River Power Co. discussed the operation of railway trains over the Montana division.

Sinking has been resumed by the Tuolumne Mining Co., the break to the machinery having been repaired. The North Butte Extension Development Co. has permitted its options on the Third Sphinx and Michigander to lapse. By the recent decision of Judge Hunt of the United States Court the Northern Pacific Railway company loses 1120 acres of valuable coal lands in Carbon county, which the company selected in 1899 in lieu of other lands. The coal lands were classified as non-mineral when the original Government survey was made, but Judge Hunt finds that the land was known to be coal land at the time it was selected by the Northern Pacific.

GOLDFIELD, NEVADA.

Goldfield Consolidated Mill Returns.—Little Florence.—Combination Fraction.—Daisy.—Fairview—Cherokee.

An important factor in the milling operations of the Goldfield Consolidated Mines Co. appears in the reduced cost of production since the starting of the new 600-ton plant on Columbia mountain. Prior to that time the Combination

mill had been treating ore with a total expense, for mining, milling, and transportation, of \$8.15 to \$8.50 per ton. In January the new mill handled the product with a total cost of \$7.31 per ton, and in February and March the cost had been reduced to \$6.31. Next to milling, the chief reduction was in transportation, which is now computed, on ore from all the mines, at 9½c. per ton, with the milling cost \$2.61 and that of mining \$3.61.

Electric power was first turned on in the new mill December 26, but with the inevitable delays and adjustments it was several weeks before the machinery was operating smoothly. During the greater part of January only low-grade ore from old dumps was fed to the crushers. It will be remembered that the refinery was not finished until later, and that none of the later stages of reduction could be attempted. Thus the month of January was by no means a criterion by which to gauge the normal output. The following official figures show the actual results of the company's milling operations during the three months following the completion of the new mill. The average recovery has increased in this period from 89 to 92%, and a reduction has been made in costs. In January the Consolidated mill treated 8564 tons, of the average value of \$22.72 per ton, and the Combination mill 2772 tons, averaging \$37.30; a total tonnage of 11,336 and total average \$26.29. The total recovery for the month was \$265,561.40. In February the Consolidated mill treated 12,967 tons, average value \$40.78, and the Combination mill 2291 tons, average value \$43.45; a total of 15,258 tons, averaging \$41.18 per ton; total recovery, \$565,781. In March the Consolidated mill treated 16,300 tons, averaging in value \$50, and the Combination mill 2710 tons of the same average value, a total of 19,010 tons averaging \$50 per ton, making a total recovery of \$838,020. In addition to this, the company shipped 341 tons of high-grade ore from the Combination, the total recovery from which was \$236,000, giving a total recovery for the month of \$1,074,020, from which is deducted the sum of \$116,788 for total expense, leaving a net profit from the month's operations of \$957,232. The refinery is now employed to its full capacity upon precipitate and concentrate, and several hundred tons of concentrate which had been stored awaiting treatment in this plant by the Hutchinson process are being shipped to smelters. During the first three days of this week bullion to the value of \$200,000 was shipped to the mints, and the same amount was sent out within a similar period last week.

At various levels and extending to a depth of 600 ft. the territory of the Consolidated company has now been developed almost continuously for a distance of 5000 ft. from the Red Top claim at the north to the rich veins of the old Reilly lease, south of the Combination workings. The ore-shoot in the latter, every description of which has called forth charges of exaggeration, is considered unique in point of quality and magnitude. In the centre high-grade streak a rich seam has been opened that yields 2 ft. of ore carrying from 300 to 400 oz. gold per ton. A raise has been completed from the 380 to the 280-ft. level. Several hundred company assay certificates at the main office vary from five to thirty ounces gold, while a few run above fifty, and offer convincing evidence of the importance of the recent discovery of a new ore deposit, opened at the 300-ft. level in the Red Top workings and in the Lucky Boy claim of the Jumbo group, in what was formerly thought to be barren ground. Near this point, from the Mohawk-Jumbo lease were taken quantities of high-grade ore, but the ore-shoot apparently gave out and the lease was abandoned. It proves that the workings missed this ore by only a few feet.

The Florence mine has another bonanza. A stope is being opened in the ore at the fourth level, 200 ft. deep, and from the cross-cut which has been run from the main shaft to the Little Florence lease workings. Across the 12-ft. face of the orebody, assays give an average return of nearly \$260 per ton. Another vein of high-grade ore has been exposed at a depth of 500 ft. in the old Engineers' lease workings, near the company shaft, but has not yet been prospected sufficiently to determine its value.

GUADALAJARA, MEXICO.

New Power Plant.—Amparo Dividend.—Projected Smelters —Ameca District —Magistral Mines.

The transmission of electric power to mines and mills in the Etzatlán and Hostotipaquillo districts of Jalisco at a comparatively early date seems certain. Manuel Cuesta of Guadalajara, who owns valuable power concessions on the Santiago river, a concession for the use of the water of lake Chapala for irrigation purposes, and a concession for a competing light and power system in Guadalajara, has entered into a combination with the Pimentel interests of Mexico City, which control the light and power situation here, and as a result it is probable that current will be transmitted to the mining districts from one of the local company's power-plants. Mr. Cuesta has contracts for the delivery of power to the Amparo Mining Co. in the Etzatlán district, and to the Casados and El Favor companies in the Hostotipaquillo district. He has planned to transmit the power from a new plant on the Santiago river. The combination makes it unnecessary to install a new plant in order to fill the contracts, and the mining companies will benefit to the extent of securing power earlier than would otherwise have been possible. The Cuesta contract with the Amparo company, which was signed last year, calls for the delivery of power by July 1. It will be impossible to comply with this provision, and a penalty of \$100 per day, or \$3000 per month, will have to be paid. The contracts with El Favor and Casados were made recently. The former calls for delivery by October 1, next, and the latter by the opening of the coming year. There is a penalty clause, similar to that with the Amparo, in each contract. Power will be supplied to each of the three concerns at the rate of \$100 per horsepower year. The Amparo will take 700 hp.; El Favor, a minimum of 250, and Casados, a minimum of 150.

The second quarterly dividend of the Amparo Mining Co., of Philadelphia, will be paid on May 10. It will be 2½%, amounting to over \$60,000. The Amparo reached a dividend basis in February last, when the first quarterly was paid. The money for the May dividend is now in bank in Philadelphia, and does not include any part of the revenue from the mines and mill for the month of March. At the annual meeting of the company, held in Philadelphia recently, all the officers and directors were re-elected. A letter congratulating James H. Howard, general manager, and his brother, William Howard, who is in charge of the Amparo reduction plant, for the excellent showing made during the last year, was authorized at the meeting. A reverberatory smelter, instead of a concentrating plant, will be erected by the Magistral-Ameca Copper Co. at the Magistral copper mines in the Ameca district of Jalisco. It will have a daily capacity of 150 tons. The decision to erect a smelter instead of a concentrator resulted from the continued development of high-grade copper ore. The order for the smelter was placed in Denver, and it is hoped to have it in operation within six months. W. E. Eells, general representative of the Towne smelter at San Luis Potosí, has made a deal for the Monterey & Union copper mines in the Ameca district. The mines are owned by Neil Trumbull of Guadalajara and H. K. Taylor of Etzatlán. They will receive \$50,000, and a third interest in a company to be formed to work the properties. The ore is rich, some of it running 35% copper. The Towne interests are behind the deal. A smelter with a capacity of 100 tons daily will be erected this year by the Philadelphia Copper & Gold Mining Co. at its San Vicente mines in the Ameca district. It is said that the ore available amounts to 75,000 tons. Development has been in progress several years. Chester P. Ray is president and M. J. Slattery general manager. Bonanza ore was recently found in one of the new workings of the Cinco Minas in the Hostotipaquillo district. According to reports, some of the ore assayed 19,000 grams silver per carga (300 lb.), or about 127 kg. per ton. The Cinco Minas are under option to H. E. Crawford, representative of the Marcus Daly estate, for \$530,000. J. W. A. Off of Los Angeles has succeeded M. N. Graves as manager of the Magistral mines in the Etzatlán district.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Petroleum in Illinois runs 30 to 32° B. and brings 60 to 68 cents per barrel.

Products of the mines furnish 64% of the total railway freight tonnage.

Fluorspar is used in making open-hearth steel, from 3 to 9 pounds being needed per ton.

In the big disseminated copper deposits there is a tendency for the metal to be segregated at the acid end of the intrusion.

Ore run was defined by Jenney as an irregular ore-body found at the intersection of an ore-horizon with a vertical fissure.

Molybdenum is used in steel-making, having the same effect as tungsten. Only half to one third as much is needed per ton of steel.

The heat-value of coke that goes into a furnace is only about one-fourth of that available for heating the hearth; about one-half is sensible heat in the gas, and about one-quarter reduces the ore.

The Rate Commission of Wisconsin has discarded the candle-power standard for illuminating gas, and substituted one based on calorific power, the one adopted being 600 British thermal units.

Cassiterite, the dioxide of tin (78.6% Sn), is the principal source of that metal. Stannite, a complex sulphide of copper, tin, iron, and zinc, is worked in a few places as an ore, but never for its tin alone.

Glass rock is a term applied in the Wisconsin zinc district to a fine-grained non-magnesian limestone breaking with a conchoidal fracture and found near the top of the Trenton formation. The ore is found mainly in or above it.

Ochre may be tested as to its value by determining the amount of oil which it will absorb. This seems to depend on both its chemical composition and on the fineness and regularity of its grains. It is gauged by comparison with the absorptive power of prepared pigments.

Pegmatite is a term first applied to the intimate interpenetration of quartz and orthoclase crystals now more often designated graphic granite. It is at present generally employed for igneous rocks of unusually coarse texture with a prefix such as 'granite-pegmatite' to indicate the composition.

Kimberlite, the rock in which the South African diamonds occur, is found in Arkansas and eastern Kentucky. Nearly identical rocks occur in western Kentucky, southern Illinois, at Syracuse, New York, and in the Highlands of the Hudson. Diamonds have only been found in the Arkansas occurrence.

Burning temperatures for clay goods are usually measured by the melting of cones, which are standardized and numbered. Common brick, tile, and fire-proofing are burned at cone 0.010, corresponding to 1742°F.; front brick, terra cotta, sewer pipe, stoneware, at cone 7, 2318°F.; fire-brick at cone 15, 2606°F.; while the lowest fusing point for good fire-clay is at cone 26, 3002° Fahrenheit.

The deepest bore-hole in the world is now said to be one drilled near Rybnik, in Upper Silesia. It has attained a depth of 7070 ft., and the intention is to deepen it, if possible, an additional 300 or 400 ft. The hole was started in December 1906 with a diameter of 16 in. At a diameter of 7 in. the diamond-drill was substituted for the churn-drill. At the depth of 7070 ft. the diameter had become reduced to 2 inches.

Molybdenite, free from copper, commands from \$4 to \$5 per unit (20 lb.) when the ore contains above 80% molybdenum sulphide (MoS_2). The average grade marketed contains about 90% of the sulphide. Large deposits of molybdenite are rare. In the desert region of the Southwest it is a mineral frequently found at or near the outcrop of copper veins. A discovery of molybdenite in that region would warrant further search in depth for copper.

Antimony ore containing 22% antimony, 13 lead, and 3 zinc would find no market. Even ores much richer in antimony and lead have recently failed to find takers. If labor conditions and fuel are sufficiently cheap it might be possible to concentrate such an ore to a high-grade regulus into which the zinc would not follow. Such an operation would be attended with considerable loss of metal, but a marketable product might be made in that manner.

Sizing, in the parlance of the millman, means, or should mean, the separation of broken or crushed ore by screening. The separation of ore into classes by hydraulic means is classification. The distinction is important, and millmen will do well not to use the terms carelessly. Theoretically a classified product consists of particles which will fall with equal velocity in water. Practically, such close classification is impossible. The desirability of classification as against sizing is still a moot question, with the argument probably in favor of classification from the standpoint of combined efficiency and economy.

Magnesite is a carbonate of magnesia containing 52.4% of carbon dioxide and 47.6 magnesia. It is used mainly for making carbon dioxide, now usually marketed as a liquid. The residual magnesia is converted into 'sulphite' (MgSO_3) and used for whitening paper. Magnesite is also used in making refractory brick, shapes, and crucibles. Small amounts are made into epsom salts for medicines and alba levis for toilet uses, as an absorbent for dynamite, and as boiler lagging. Limited amounts are used in making oxychloride cement, as an adulterant in paint, to prevent scale in boilers, and for various chemical and electro-metallurgical purposes.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Cyanidation of Silver Ores.

The Editor:

Sir—I have read with interest the articles on the cyanidation of silver which have appeared recently in the MINING AND SCIENTIFIC PRESS. It is apparent from these that the chemistry of the process still presents many unsolved problems. In connection with the Wall Research Fellowship at the Utah State School of Mines, I am conducting a series of experiments on silver ores and minerals. A few of the more important results are tabulated below.

solution in both cases. With some of the silver compounds on the other hand, the introduction of lime or of an alkali is an important aid to extraction, and in the case of AgCl oxygen plays no part in the reaction. Percolation, soaking, and air-agitation tests have all been tried, but for the purpose of securing comparative results the ordinary bottle test is most effective.

The experiments given below, except those from which the air was excluded, were made in 8-oz. salt-mouth bottles. Ten of these were clamped in a frame, and rotated by a small water-motor. The speed was so regulated that the contents of the bottle would fall from one end to the other during each half revolution. As the bottles were only partly filled, the agitation and aeration were probably both as favorable as will obtain in practice. Most of the tests were run over night and the temperature varied from 10 to 20° C. In Table I are given results ob-

In working with ores from various mines it was found that the many unknown factors made generalizations dangerous. Even a chemical analysis leaves important facts unknown, such as the form in which the elements are combined. Therefore many of the experiments were conducted on artificial ores in which active agents have been introduced one at a time. Not only is it true that the same factors affect the solubility of gold and silver differently, as pointed out by Mr. Caldecott (MINING AND SCIENTIFIC PRESS, Aug. 29 and Dec. 12, '08), but the character and extent of this difference is due to the mineral form in which the silver occurs. In the case of metallic silver, experiments indicate that the effects are the same as those on gold, the only difference being in degree. For example, the introduction of lime decreases the solubility of both native silver and gold in a cyanide solution. Also it is well known that oxygen, or an oxidizing agent, is essential for

tained on silver sulphide precipitated from a silver nitrate solution: 250 mg. of Ag₂S, equivalent to 217.7 mg. of silver, was agitated 17 hr. with 150 c.c. of a 0.5% solution of KCy. The extractions are based on solution-assays.

Duplicate tests, three of which are included in the above list, show that the variations in speed of rotation and temperature did not seriously affect the results. The air-tight tests, 13-25, were made in 160 c.c. Erlenmeyer flasks. After adding the Ag₂S and other chemicals, with the exception of KCy, the flask was filled with distilled water and the contents boiled under reduced pressure for about 15 min; 800 mg. of pure KCy was then dropped in, the flask tightly sealed, and quickly cooled to the temperature of the room.

The amount of lead and mercury available in the compounds added to tests 4, 7, 9, 11, 17, 20, 21, 23, and 24, is the computed weight necessary to combine

with the sulphur resulting from the complete decomposition of the 250 mg. of silver sulphide. The reason for the method of treatment in each case, and the most probable explanation of the effect produced, would involve a discussion of ionic equilibrium and other fundamental laws of chemistry, obviously beyond the scope of the present article. But readers who have followed closely the previous discussions of the subject (MINING AND SCIENTIFIC PRESS, May 2, Aug. 1, 8, and 29, Sept. 26, and Dec. 12, '08) will, I think, readily understand the 'wherefore' in the above experiments. It is clear that oxygen plays an essential part in dissolving silver sulphide in cyanide solutions. It is more important when litharge is the precipitant of soluble sulphides, than when lead acetate is used. It is also interesting to note that in

mixed and quartered. Duplicate assays on this prepared ore gave 47.70 oz. silver per ton. 50 gm. of ore was introduced along with 100 c.c. of solution into 8-oz. bottles and agitated as in the previous tests. Agitation by compressed air on larger samples gave similar results. Extractions are figured on solution-assays in all cases except where these are shown to be in error by similar tests and by tailing assays. In cases of almost complete extraction better results can be obtained by assaying the tailing. Except where otherwise stated, lime is present to the extent of 6 lb. per ton of ore, and the samples were agitated 17 hr. in a 0.5% KCy solution.

The above experiments, along with others not tabulated, prove rather conclusively that the usefulness of lead salts is limited to those ores containing silver

cases where there is no excessive consumption of cyanide, the ratio of the silver dissolved to the cyanide consumed closely approximates 216 : 325. This is the proportion demanded by the most generally accepted equations.

The largest number of my experiments are being carried out on silver minerals of a high grade of purity. These were secured from the Foote Mineral Co. and from the Museum of the University of Utah. One example will serve to illustrate the method of preparing the so-called 'ore samples' from these silver minerals. 1.6 gm. of a crystallized specimen of pyrargyrite (Ag₃SbS₃) was crushed with a few grams of quartz sand in a porcelain mortar, to pass a 100-mesh screen. This was then mixed with 550 gm. of quartz sand which had been ground on a stone bucking-board to avoid the introduction of iron. After adding 1.6 gm. of lime the sample was thoroughly

as argentite, or in which there is danger of the silver being re-precipitated as Ag₂S. In case the silver is present as proustite, pyrargyrite, or tetrahedrite, the addition of lead salts in the presence of lime would seem to retard rather than assist solution. This fact will probably help explain the poor effect of lead compounds applied to a certain Mexican ore, as instanced by Mr. Caldecott (M. & S. P., Aug. 29, '08). The chemical reactions involved are obscure. The addition of stibnite, in the presence of PbO, in (3) is fatal. Also tests 9, 10, and 16, Table I, show its evil results. In case of the difficultly soluble silver minerals, I have not experienced the beneficial results of adding Hg₂Cl₂ (see tests 5, 6, 10, 11, 16, and 20), found by Mr. Hobson (M. & S. P., Aug. 8, '08) to hold true for some Mexican silver ores. Possibly some essential factor is lacking in my tests.

The use of litharge seems preferable to lead ace-

tate when dealing with soluble sulphides, for reasons mentioned by Mr. Eye. Also it may be added in excess without seriously affecting results. I should like to know if its limited use in practice is due to controlling patents. I have attempted little more than the tabulation of a few experiments in the present article. I shall later present fuller data in graphic form.

THEO. P. HOLT.

Salt Lake City, February 26.

Rock Determinations.

The Editor:

Sir—I sent you six specimens of rock the other day by mail for determination. As a matter of curiosity, I had five graduates of the foremost mining schools in America make a determination independently. The results are so curiously different that I append the results, with a column for the results you may find in San Francisco:

No.	1	2	3	4	5	6
1	Trachyte	Volcanic Ash	Rhyolitic Trachyte	Trachyte	Tuff	Quartz Porphyry
82	Basalt	Quartz Felsite	Diabase	Basalt	Andesite	Basalt or Basic Andesite
86	Basalt	Andesite	Basalt	Felsite	Andesite	Andesitic or Basaltic Trap
103	Felsite	Felsite Breccia	Trachyte	Felsitic Rhyolite	Trachyte	Pyritized Rhyolite
102	Trachyte	Trachyte Breccia	Trachyte	Trachyte Porphyry	Rhyolite	Pyritized Rhyolite Porphyry
85	Diabase	Diorite	Diabase	Felsitic Diorite	Felsite	Metamorphosed Andesite

These cannot all be right, and it might be worth the candle to make a note in 'Concentrates' to point out how the errors in determination have arisen. Most (in fact, almost all) are recent graduates of Columbia and Houghton.

A. T. TYE.

Arizpe, Mexico, February 9.

[The foregoing implies an inaccuracy in petrographic determinations which the internal evidence of the communication itself fails to justify. In view of the fact that 'No. 6' in the table happens to be the petrographer of the MINING AND SCIENTIFIC PRESS, we are able to state that no slide was prepared for microscopic examination, nor was a chemical analysis made; for 25 cents the labor that would cost anywhere from \$10 to \$15 could not be performed. The rock determinations by this journal are better than those which a well-trained geologist can make in field or camp, because superior laboratory conveniences are available; yet they are only close approximations to accuracy. It might easily be possible, for example, to call a trachyte a 'rhyolite' when a typical variety was not presented. Many rocks pass from one to the other by insensible gradations; near the border-line it is immaterial whether it be classed on one or the other side, unless important issues are at stake. Inspection of Mr. Tye's table shows a most striking agreement among the several analysts, excluding 'No. 2', who was lacking in proficiency throughout. For work of the order which a field-geologist would do, which is manifestly the kind performed, the result is a vindication of the excellence of the training given in the schools. If the determinations were to be made microscopically we would

expect this group of men to be in complete accord.—EDITOR.]

What Is an Ore?

The Editor:

Sir—I have read with interest the article on 'What Is an Ore?' by James F. Kemp, and consider that his definition is still too indefinite for general application, particularly as regards the needs of the miner and the layman. No complete gradation of quality is available, such as 'high-grade', 'low-grade', or 'too low-grade to pay under present circumstances'. I would, therefore, offer the following as my interpretation of the English word, and believe that it will cover all classes of mineral compounds known in common parlance as 'ore', namely, the constituent in a rock matrix, either metallic or metalliferous, of sufficient commercial value to warrant the exploitation of the deposit and the reduction of the output to a marketable commodity; 'high-grade' ore, which

returns a large profit; 'low-grade' ore, which, (1) returns a small profit, (2) only pays the expenses of operation, (3) can only be mined at a loss, but may be of value at some future time.

W. J. ADAMS.

San Francisco, March 25.

Oil Measures in the Coalinga District.

The Editor:

Sir—A few remarks from one familiar with the conditions may be of interest to your readers in connection with the able article by William Forstner in your issue of March 13, 1909, entitled 'Oil Measures in the Coalinga District'. Considerable criticism of the work of the geologists Ralph Arnold and Robert Anderson is being indulged in by persons locally interested in the Coalinga and Kreyenhagen oil-fields, and an attempt will be made to give, in a disinterested manner, the causes leading to the controversy. Certain lands, described in Bulletin No. 357, U. S. Geological Survey, were withdrawn from entry except as mineral land, the recommendation for such withdrawal presumably being made by the geologists. The writer has no information as to this, but it seems probable that instructions to the geologists would call for segregation of such lands as were deemed of value for their mineral contents, other considerations being neglected. Prospecting work was being carried on outside of the area withdrawn, as at the properties named by Mr. Forstner, and the segregation of the land acted in two ways to the detriment of such companies. First, the stock was depressed by the classification, which was doubtless detrimental to some if not to all of the companies. Second, title to

the properties could be clouded by those who chose to lay homestead claim to the lands. Protest was common, and other lands were later included with those already withdrawn from entry. As to the local conditions, it should be stated that in the district under discussion homesteading is a method commonly used by locators to obtain title to lands which are practically worthless except for the possibility of their bearing oil. Homestead 'shacks' are erected, and a few furrows ploughed under the guise of preparing a piece of land for cultivation. Many such locations are in places where irrigation would be impossible, and furthermore are near lands where attempts have been made to farm, and numerous monuments of the failure are seen in the form of deserted houses and barns and fragments of fences. Doubtless the second segregation of land is just, as it serves to prevent such abuse, and allow the miner (for the oil man is a miner, although the idea may not occur to the casual observer) to proceed with his prospecting without fear of the 'jumper'.

Another local condition quite worthy of mention is the fact that a large portion of the small oil-operators know absolutely nothing of elementary geologic principles, and their criticism of geologic work is worthless. Many thousands of dollars are expended on lands where a glance is enough to show the geologist that the possibilities are a minus quantity. With considerable knowledge of geologic conditions in the Coalinga district, the writer believes that the report by Arnold and Anderson will stand the test of development, and that local operators will profit more by studying the bulletin and governing their prospect work by its suggestions than by criticising.

R. P. McLAUGHLIN.

Panoche, California, April 3.

Churn-Drill Sampling.

The Editor:

Sir—I have read with great interest W. E. Thorne's article in your issue of March 6. I quite agree with him in saying that no property should be considered as proved when prospected by drills alone. There are so many points of information required to give complete knowledge of the ground, impossible to obtain by means of a drill alone, that it is surprising what confidence is put in results obtained in this way. In the examination of a placer property, the object is to determine the amount of gold in the ground that can be saved by practical methods. To do this in the best manner, the natural way would be that which most nearly followed the approved and tried methods employed in actual working. But in the majority of cases we are compelled to find other means. This necessity led to the method of prospecting by drills in California, and it has proved of such good use as to have replaced all others. In general, it can be said that returns have justified the method; in consequence, operators complacently take the results, as they have just as complacently taken other things that have become established.

The examination of a property by prospecting with drills alone lacks information on one of the very essentials of successful operation, namely, the gold-

saving. Gold taken from the bottom of a drill-hole cannot be consistently tested for amalgamation, for the character of it is liable to be changed by the grinding. In the mind of the layman, it is generally considered that, to make a placer property successful, it is only necessary to have the gold in the ground. Failures arise from other troubles.

When placers were worked by inexpensive methods, as in the old days, longer chances were taken on reports of a property, from the fact of the smaller investment and the many rich properties available. In many cases the loss of half the gold would not be a cause for worry, as the remainder was enough to make the investment profitable. At the present day, however, the minimum loss is regretted, both because the properties are much lower in gold content and because economic conditions receive more consideration. The investment necessary is greater and the preliminary investigation should be correspondingly closer.

In a locality like Oroville all the conditions are practically determined before a dredge is even considered, and the drilling of the property is only necessary to determine the gold content. In a new locality additional means must be employed to determine the other essential conditions, and this should follow what we know to be best in current methods of operation. It is just as essential to know how the gold must be saved, and to make satisfactory experiments to this end, as it is to know how much gold there is in the ground. Of what use would ground be to an operator which would prospect 50c. per cubic yard, if he could only save 10c. out of it?

This brings us down to the one way out of the difficulty, which is to sink shafts, as suggested by Mr. Thorne, and to handle the dirt from them in the manner most nearly approaching actual working conditions. True, this may not always be possible, on account of water, but in many cases a small pump will take care of that. Objection is frequently made to the expense of all this, but from the standpoint of good business this is so small, compared to the proposed investment, as to be comparable to insurance.

As to the need of these precautions, I can say that I know of at least one case where a large sum of money was expended in purchase of equipment and property, yet up to the time operations were started, the management did not know whether the gold would amalgamate or not. I have under observation another property, which pays about the same proportion of 50 to 10 mentioned above, comparing results from prospecting and the returns from the sluice-boxes. In this, as in every other phase of the mining game, we can truly say that 'history repeats itself', but that it does, is largely due to ignorance and poor business methods.

CARNEY HARTLEY.

Denver, March 17.

Steam-plant coal consumption per horse-power-hour ranges from 1½ lb. in large highly refined steam plants to perhaps 5 lb. in smaller and simpler ones; the corresponding values for gas plants will range from a little over 1 to a little over 2 pounds.

ECONOMIC CONDITIONS IN COLOMBIA.

Written for the MINING AND SCIENTIFIC PRESS

By F. LYNWOOD GARRISON.

Since the issues of the MINING AND SCIENTIFIC PRESS of January 2 and February 6, 1909, containing articles by myself concerning Colombia, I have received many letters asking about the climate, mining laws, land titles, labor conditions, etc. As it is inexpedient to answer such communications individually, I have prepared the following sketch, covering the subjects, as far as my limited knowledge will admit.

It seems to be the universal verdict of travelers and explorers in South America that the moist tropical sections of the interior, wherever the elevations are less than 1000 ft. above the sea, are malarial, and that these fevers are more malignant in some places than in others. On the coast, on islands swept by the trade winds, or where conditions of semi-aridity exist, as in certain parts of the island of Santo Domingo, malaria is infrequent or non-existent. In the valley of the Magdalena river and its tributaries, wherever the elevation is less than 1000 ft., malaria is common, and appears to be nearly as dangerous to the natives of the mountain districts as to foreigners. The lower Cauca valley, in the Cáceres district, is no exception to this rule; the little town of Cáceres, about 600 ft. above tide, is situated on a high gravel bank rising above the Cauca river 30 or 40 ft.; the main street is completely and the side streets are partly paved with cobblestones, and have such steep grades that no stagnant water can collect. As a consequence I was not in the least troubled with mosquitoes in the old warehouse overlooking the river that my party occupied in this town. At every other place in that region, except on high elevations in the mountains, mosquitoes are common, and of the *anopheles* or malarial type. Above the town of Cáceres the Cauca valley is shut in by mountains and the current of the river becomes much swifter. This does not appear, however, to prevent mosquitoes from breeding, as they are to be found everywhere in the jungles, though infrequent on cleared spots high up on the banks above the stream. It is evident, therefore, that if one desires to avoid risking health and life when making a prolonged stay in the lower Cauca valley, it is absolutely necessary to occupy a well-ventilated, thoroughly screened house on a high completely drained bank above the river, and to be provided with an abundance of plain, well prepared, and wholesome food. If these precautions are observed and pains be taken to avoid mosquito bites when working in the jungle, which is a difficult thing to do in a hot country, good health should be assured at all seasons of the year. All the low valleys of Colombia appear to be regarded with dread by the natives of the healthy mountain districts. Possibly some of this evil reputation is undeserved, although it would seem that there are places in these districts deadly to white men, as well as to Indians.

Cases of beri-beri have been known among foreigners in Colombia, and it seems that this disease, as well as leprosy, are not uncommon with natives. I myself saw a number of cases of elephantiasis, some of goi-

tre, and a few which I took to be leprosy. Although loathsome, no disease carries the terror of beri-beri, and I see no reason why they should be specially feared when cleanliness is observed and care is taken in selecting the persons to whom clothing is given for washing. They used to tell me in China, whenever the wash was slow in getting in, that the washerman and his family were probably wearing my clothes, a discomfoting thought to anyone who knows how dirty a Chinaman can be!

Before leaving this subject, it might be of interest to observe that there is much ignorance among educated people regarding the group of diseases commonly called malaria. I have often heard good physicians at home dismiss the subject with the remark, "Oh, chills and fever. That's nothing. Easily cured with quinine." So I thought also before acquiring in my blood a choice assortment of *plasmodium malariae* from the Cauca and Magdalena valleys. The *plasmodium malariae* was described by Laveran some thirty years ago, and that this germ is transmitted from one person to another by a certain type of mosquito, of the genus *anopheles*, has been proved beyond question in the last ten years. The physicians on the Panama Canal Zone classify malarial fevers under the following seven heads, and during the year 1898 treated in the hospitals the number of cases indicated by the figures:*

	Discharged.	Died.
Malarial fever	816	42
Aestivo-autumnal malaria	3837	13
Tertian malaria	2260	1
Mixed malaria	185	..
Clinical malaria	4849	27
Malaria cachexia	200	3
Hæmoglobinuric fever	29	11

These fevers may be classed thus: (1) quotidian malaria, in which the fever attacks every day, and is difficult to cure; (2) tertian malaria, in which the fever comes every other day (72 hours), the specific germ of which is known as *plasmodium vivax*; (3) quartian malaria, in which the fever returns every fourth day, the germ of which is known as the *plasmodium malariae*; (4) aestivo-autumnal malaria, the usual tropical variety; (5) pernicious malaria, the deadly blackwater fever, known scientifically as *laverania malariae*; (6) some people differentiate further and distinguish a bilious malaria, which is accompanied by sickness and torpidity of the liver, and intense headache, a type that is often fatal. Probably these symptoms may be common to any or all the above varieties, depending upon the constitutional idiosyncrasy of the individual affected. These classifications are obviously faulty and unsatisfactory, for all the peculiarities of this disease are by no means known or understood. All malarial germs are protozoans, that is to say, they are not bacteria. The life history of a malarial parasite in the human system may be summarized as follows: In the human blood these protozoa inhabit the red blood corpuscles and go through a sporulating existence which may continue indefinitely unless checked by quinine or in some other way. In the red corpuscles the parasite

*Report of the Isthmian Canal Commission for the year ending 1908, p. 290.

appears as an amoebula which gradually grows until it nearly fills the interior of the corpuscle, digesting apparently the red coloring matter of the blood and forming as a result pigment spots in its interior.

ber of spores. The walls of the corpuscles then break and the spores are liberated into the blood serum. From a single infection this sporulation or liberation of spores or toxins takes place practically

On reaching full growth the nucleus of the amoebula subdivides, each division gathering about itself a certain amount of protoplasm until, instead of a single amoebula, the corpuscle contains a large num

simultaneously and marks the beginning of the malarial spasm or chill. Quinine is the only cure for malarial fevers, and when taken in a liquid form it acts more quickly than in the condition of an or-

dinary hard pill. In the French Army in Africa, malaria is treated with sub-cutaneous injections of quinine of from one-half to two grams daily. The quinine doses are most effective when administered in any manner just as the chill or spasm is about to begin. In severe cases doses should not be less than ten grains, and medical assistance must be sought as promptly as possible, especially in the tropics.

I have heard of some cases of the deadly 'black-water fever' in Jamaica, but none in Panama or Colombia, although, like the beri-beri, if once introduced it may be difficult to stamp out under favorable conditions for its propagation. The blackwater fever is common in Africa, just as beri-beri is in China and Japan. On the whole, it is probable that the climate of the low valleys in Colombia is much the same as that on the Isthmus of Panama, and will be quite as dangerous to health unless precautions be taken. The efficacy of such care on a large scale is now to be seen in the Canal Zone, and there would seem to be no reason why similar precautions cannot be exercised on even the smallest engineering operation in Colombia. It will naturally be asked, why are any operations attempted in these unhealthy sections; why not go to the higher and healthier places? The answer is that it is chiefly in this low-lying country that we find the alluvial gold-bearing deposits which have in the past and will even more in the future, make Colombia famous.

The mining laws of Colombia appear to be liberal, and the government is fully alive to the advantages of attracting foreign capital and enterprise. President Reyes has taken a sensible and decided stand against granting concessions to speculators and investors without strong financial backing, who he fears would simply peddle these grants and end in tying up valuable properties for a term of years, to the detriment and hindrance of the legitimate development of the country.

Land titles in Colombia, especially when coming from individuals, usually appear to be open to suspicion: in fact I have been told that the State Department at Washington has had difficulty in protecting American rights in this particular. Both private persons as well as our own Government officials, who have had experience in Colombian matters, unhesitatingly counsel caution. Such difficulties are apparently chronic in countries that have suffered from repeated governmental revolutions, and they are perhaps the greatest drawback to development.

The Colombian Government exacts an export duty or royalty tax of 1% on all gold exported from the country. When the gold exported comes from a concession granted by the Government, 5% is charged on the value of the gross production, but an additional export tax is not exacted. Emerald mining is a government monopoly, and individuals are prohibited from undertaking it. Coal, and I think also petroleum deposits, belong to the Government: they are not sold but leased for 50 years, subject to a royalty of 15% on the net profit in the case of coal. All improvements are left to the Government at the expiration of the lease. From two to three years are allowed to develop the coal and to begin operation.

A bond must also be given as evidence of good faith on the part of the operator. Considering the fact that there are few coal mines operating in Colombia, although the country contains vast coal deposits, these terms are onerous, and will tend to discourage development and investment of foreign capital. The difficulties and expenses incident to new enterprises in countries like Colombia, are grievous enough without being saddled with a royalty which would be considered large even in some districts of the United States. Mining machinery is admitted free from customs duties, but I do not know what restrictions, if any, surround the importation of explosives.

Regarding labor, we may turn again to Panama for comparisons, because similar climatic and ethnologic conditions exist there, and have produced like results in the way of population. The Panamanian natives have been found indifferent laborers in the work on the Canal Zone. Doubtless similar difficulties will be encountered in obtaining and retaining laborers in the unhealthy valleys of Colombia. The natives from the mountain districts in Colombia are said to be fairly good workers, but the same can certainly not be said of the valley dwellers, who have about two-thirds negro blood. The population of Colombia is sparse, and does not appear to be increasing; on the contrary, I have been told it has considerably decreased by reason of the relatively great losses of life during the revolution which occurred about six years ago. On the whole, the prospect for securing good labor for engineering undertakings in Colombia does not seem to be encouraging, and it is probable that large undertakings will be hampered unless laborers can be brought in from other countries.

South America is pre-eminently a continent of the future, a place where the super-abundant population of Europe and North America will ultimately go. Its possibilities are enormous, and some sections could support a population as dense as that of India or China, when in the future some clever biologist succeeds in discovering an antitoxin that will destroy or neutralize malarial poisons.

Since writing this sketch an article on 'Travel in Colombia' by Courtenay De Kalb has appeared in the issue of March 6. Although Mr. De Kalb knows a great deal more about Colombia than I do, he has been polite enough to ask me for criticism of his article. The only point on which I do not agree with him is in his affirmation that the malarial mosquito is exclusively nocturnal in its flight. I have the authority of one of the most prominent entomologists in this country for the statement that the *anopheles* mosquito is likely to be about and bite in the day time, but of course it is less active than at night. This confirms my own experience, for I have been frequently bitten in the middle of the day while at work in the jungle along the banks of the Cauca river, by mosquitoes that I am sure were of the *anopheles* type. As there are 30 different species of this mosquito, it is possible they may not all carry malaria, but the entomologists tell me it is certain every one of these may upon occasion develop that tendency.

BOSTON CONSOLIDATED, BINGHAM, UTAH.

Written for the MINING AND SCIENTIFIC PRESS
By COURTENAY DE KALB.

South and southwest of the area owned by the Utah Copper Co. in Bingham canyon lies the property of the Boston Consolidated Copper Co. Unlike the

more pronounced feature of the alteration. That circumstance, however, has not been the cause of sufficient resistance to denudation to materially determine the physiography; the ridge was formed as a result of the harder quartzite which constitutes the main mountain mass. The great monzonite area exposed in Bingham canyon extends southward into the

Incline-Tramway, Boston Consolidated Mine.

Utah Copper, the Boston Con. has mines of high-grade ore—ore which is basic and rich enough to go to smelter without preliminary concentration; but it also owns a large block of the monzonite disseminated low-grade copper ore which is being so successfully worked in Bingham canyon. The Boston Con. owns the highest portion of the impregnated monzonite mass, which reaches an altitude of about 7600 ft. at the summit of the ridge. The rock in this direction is more fractured, and silicification has been a

drainage-basin of Carr Fork in the form of a narrow elongation. In this are retained two large remnants of the quartzite which had been lifted up by the intrusive igneous rock. The character of the monzonite in the mine of the Boston Con. is not perceptibly different from that being worked by the Utah Copper Co., but the line of demarcation between the leached and oxidized overburden and the subjacent, secondarily enriched ores is subject to greater irregularities, the outline often being decidedly serrated.

The Boston Con. owns 49 acres of impregnated monzonite carrying 1.5% copper, from which an estimated production of 56,000,000 tons of ore can be derived. In addition to this, there are 107 acres of 1% ore, which may constitute a valuable asset in the future, for although immense copper deposits are being developed in many parts of the world, the exhaustion of ore that can be now profitably worked with copper selling at 12 cents per pound is proceeding so fast that the revelation of fresh resources by development has no tendency to depress the price. Whatever may be the fluctuations in copper quotations within the next few years, the future, counted in decades, must call for the utilization of ores of lower copper-content than can be mined today. This will necessitate a higher average price for the metal, unless modern improvements in mining and metallurgy reduce the cost of treatment equally with the average diminution in grade.

While the average copper-content of the orebody developed by the Boston Con. is placed at 1.5%, much ore of higher tenor exists, which is characteristic of the more highly fractured portions of the monzonite. For example, the monzonite area extends eastwardly into the ground of the Ohio Copper Co., where the silicification has been still more complete, resulting in greater irregularities in the distribution of the metal; that is, there are zones of higher concentration. It may be observed in passing that the more highly silicious ores are claimed to yield a larger percentage of extraction by concentration. The low-grade ores of the Boston Con. contain 0.25 oz. silver and 0.003 gold per ton. On the basis of 12c. copper and 75% net recovery upon copper and 50% on gold and silver, these ores would yield a gross return of \$3.07 per ton, and it is safe to say that the total cost of operation will fall below \$2 per ton.

The conditions presented by the monzonite orebody in the territory of the Boston Con. have led to a mining practice at variance with that adopted by its neighbor. Both caving and steam-shovel work are utilized, but with fundamental differences. The open-cast work is conducted in benches of moderate height, 50 ft. being the elevation of bank aimed at; this, however, is subject to considerable variation arising from surface-irregularities. The rock is shattered by blasts in deep holes bored by a Keystone drill. The No. 2 drill is used, and the holes are cased with 6-in. well-casing. The holes are drilled 25 ft. from the edge of the bank, so that with each blast a cube of material, approximately 25 by 25 by 50 ft., or 1158 cu. yd., is shaken. The bottom of the hole is first 'sprung', that is, chambered, with a charge of 50 lb. of 40% dynamite; a large charge of Trojan powder, consisting of 500 to 600 lb., is then introduced, and exploded electrically with 6X caps. The Trojan powder is said to be particularly well adapted to this work; it is quite insensible to ordinary shock, does not freeze, and is unaffected by moisture. The 30% grade of powder is employed for bank-blasting. The cost of drilling the holes is said to fall below 90c. per foot, including necessary renewals of casing, most of the casing, however, being recovered undamaged after each blast. At one time an experiment

was made with a hole 120 ft. deep; it was blasted with a charge of 4 tons of 35% dynamite. The method of blasting a lower bank, however, is considered more satisfactory. The excavation is done by Marion and Vulcan steam-shovels of the 95-ton type with 5 cu. yd. dippers. The company owns 4 of these machines. The usual crew of engineman, craneman, fireman, and 4 pitmen, is employed. The ore is loaded upon cars on a narrow-gauge track, and conveyed around the spur of the mountain to the mine-bin on a gradient of about 2%. The cost of the ore mined and delivered to the bin is said to average 18¾c. per ton. The use of a narrow-gauge service-railway offers some advantages over the standard-gauge employed in Bingham canyon. It necessitates less cutting for the track, and is much more flexible.

From the mine-bins the ore is sent by a gravity-tram 2100 ft. down the mountain-side to a great cylindrical steel bin at the level of the Rio Grande Western railway main tracks in Carr Fork, whence the ore is shipped to the concentrator at Garfield, 27 miles distant. The bin is constructed of ¾-in. steel at the bottom and of ¼-in. sheet at the top; it is 60 ft. high, and 36 ft. diam. Opposite the chute, where the ore is dumped from the skips, it is faced with heavy lagging. The incline has a double track, of 3-ft. gauge. The grade changes three times in the course of the descent, beginning at 29° from the horizontal, flattening to 24, and finishing at 14. The cable is held down to a proper angle for traction by knuckle-sheaves carried on bents which straddle the track at intervals. On this tramway 12-ton skips are operated at a speed of 400 ft. per minute, and each car averages 15 trips per hour. No effort is being made to attain a high capacity at the present time, when the incline is delivering 2400 tons per diem into the steel bin, or 200 skips in a shift of 10 hours. These cars or skips are handled by a brake-system manufactured by S. B. Stine & Son of Osceola Mills, Pa., patterned after those employed in coal mines. The apparatus is simple and safe. The cable passes in the shape of a figure 8 around two drums, one 90 in. diam. and the other 110, placed tandem, making four laps around each drum. The drums are placed with their axes vertical. The faces are made broad for friction-brakes which pass around each drum, and are fastened near one edge of a disc placed between them; a partial revolution of the disc thus serves to tighten the brakes. The steel brake-bands are faced with wooden blocks set with the grain horizontal. In order to prevent glazing of the wood from the formation of carbon under the heat of friction, holes are bored through the blocks and filled with babbitt metal. This simple expedient proves an efficient remedy for the evil of carbonization of the wood. The brakes are controlled by compressed air, and a counterweight is provided which securely locks the wheels if the air-mechanism fails, or if the air-pressure falls below 60 lb. The entire system of drums and brake-device for operating this double-track incline with 12-ton skips, cost only \$8500 delivered at Bingham, Utah.

On the incline are three bins, one at the top for ore mined by steam-shovel, and one several hundred feet

lower taking ore from the main tunnel, and another still farther down the mountain. A single-track electric haulage system handles the ore on the main tunnel-level. These loading bins are equipped with a simple and efficient sector-gate, which opens downward and closes upward, designed by the engineers of the Boston Con. At the constricted lower portion of the bin the ore rests upon a heavy iron casting made on the arc of a circle, with a flat plate in a position radial to the arc, so placed that it constitutes the front of the bin-gate which is closed by being moved upward, and lies flush with the inclined

with vertical walls. Pillars 20 ft. wide are left between the stopes, and those are subsequently caved by stopes raised below until the supporting arch becomes too weak to sustain the burden. A drift is driven through the block, as shown in the plan (Fig. 1), 38 ft. from one side of the block. The drift ER is originally 6 ft. wide, and is subsequently widened to 12 ft. Cross-cuts, XX, are then driven through the ore which is to be left as a pillar, PP, to the ground which is excavated by the stope S. This area, 22 by any length up to 400 ft., is under-cut, the broken ore being trammed out. Overhand stoping then proceeds until the arch shows signs of weakening from the pressure of the pillar or the overburden above. The successive stages of the process are shown in the elevation, Fig. 1. As the pillars and stopes alternate, the relative volumes are approximately as 1 to 1.37, but as the arches above the stopes are about 8 ft. thick when caving ensues, the volume broken by caving is greater than that mined by drifting and stoping, the figures being almost exactly reversed. A series of 7

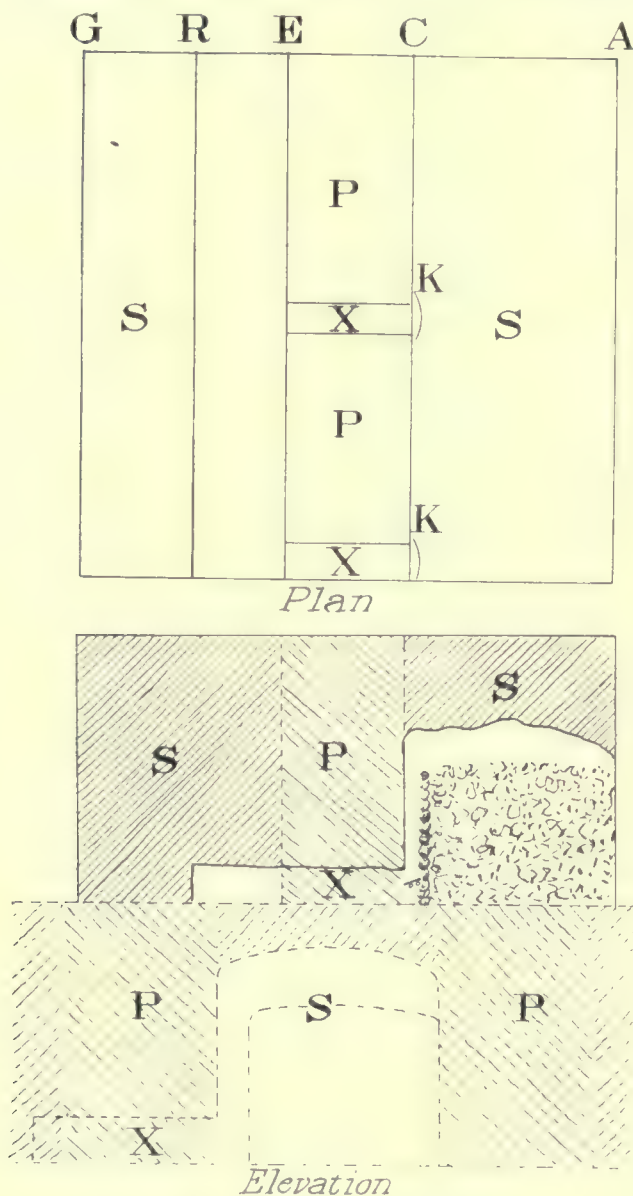

Fig. 1. System of Cave-Mining.

bottom of the bin when moved downward, forming an extension of the bottom plate of the bin upon which the ore can smoothly run when this sector-gate is down or opened. The gate is pivoted at the centre from which the arc plate is subtended, and is operated by power applied from a compressed-air cylinder at the end of a level. The gates are 30 in. wide, and the air-cylinders, operating them, are 10 by 30 in., using air at 60-lb. pressure.

The system of cave-mining at the Boston Consolidated was elaborated by Louis S. Cates, the mine superintendent. In principle it consists in carrying up stopes 100 to 400 by 22 ft. in horizontal section,

Fig. 2. Caving Large Blocks.

stopes and pillars would involve, in the collapse from caving, a total volume of about 755,000 cu. ft., with the preliminary excavation of about 68,000 cu. ft., the ratio of ore broken by caving to that won by ordinary mining rising accordingly to about 11 to 1. Stopes will be carried from the lowest tunnel, where ore is loaded in cars, up and underneath the pillars above, thus drawing all ore directly from stopes to the main haulage system. As the haulage in the main levels is done by trains operated by electricity, it is seen that the expense of handling will be reduced to a relatively small item. The volume of the ore after being broken is increased so that it would occupy about one-third more space than the original 'ore in place'. Consequently, after the first slice has been removed in starting a stope a constant distance between the broken ore and the roof is maintained by drawing about one fourth of the material blasted.

Waugh, Leyner, Sullivan, and Murphy stoping-drills are employed, and have proved most efficient. The duty of one machine is from 20 to 25 holes, 7 ft. deep, per shift of 8 hours. The holes are drilled from 4 to 6 ft. apart. Two shifts are employed, and the holes are fired after each shift. Three machine-men and three muckers are at work in each stope. The three machine-men 'spit' the holes, which are loaded with $1\frac{1}{2}$ to 4 sticks of 30% Hercules dynamite. The

fuse is cut in 7-ft. lengths, and burns at the rate of 18 in. per minute. Thus the time allowed for spitting 25 fuses and escaping to safety is 4.7 minutes. At the present time work is progressing in six stopes, and the output of the mine is 2000 tons per day, which includes ore extracted during development. The regularity indicated by the diagrams is not maintained in practice. One stope is 480 ft. long, and another is 140, with a height of 115 ft. The system

Fig. 3. V-Notch Stope-Chute.

of mining has been a process of evolution by experiment, and it has been necessary to proceed cautiously, profiting by each trial in dealing with this particular orebody. Considerable difficulty has been pre-

Fig. 4. Plan of Stope-Chute.

sented by the slips, which extend for great distances through the ore. These have slickensided faces, and, as is usual when such dividing surfaces are a result of alteration instead of jointure or faulting, they display a tendency to conchoidal forms.

An interesting detail in connection with the stopes is the manner of making ore-chutes. These are exceedingly simple and inexpensive. From the terminus of each cross-cut from the drift ER (Fig. 1) a shallow but wide V-notch is maintained in the wall of the pillar, about 2 ft. 6 in. wide in horizontal section (Fig. 3). Lagging poles are laid across the notch, behind which the broken ore in the stope is filled (Fig. 3 and 4). A loading-pocket is provided at the bottom of the chute, constructed at such a height as to admit of drawing the ore into a car on the cross cut. The lagging employed is 6 in. diameter

Miners are paid \$3 and muckers \$2.50. The cost for labor alone in driving levels and cross-cuts, which are 6 by 8 ft. in section, is said to amount to \$2.25 per running foot. The powder used will average about 3/4 lb. per ton, a ton being nearly 12 cu. ft. of ore in place.

COSTS OF DREDGING.

In a recent editorial note we referred to dredging costs. Here are the details. The costs given cover the operating expenses, the cost of all repairs necessary to keep the dredges in first-class working condition, and the cost of extraordinary breakages and accidents; all of which latter are properly included in dredging costs. Estimates of costs which do not include the last mentioned items are to that extent fictitious.

- 1. A dredge having 3 1/2 cu. ft. buckets, digging in ordinarily loose gravel and sand.

OPERATING COSTS IN CENTS PER CUBIC YARD.

	—YEARS—						Average for 6 years.
	1.	2.	3.	4.	5.	6.

Dredge No. 2, working in such ground as is No. 1, would operate at a total cost of about 5.59 cents.

Cobalt, so closely resembling nickel in its general characteristics, does not seem to behave like it when alloyed with iron. It apparently has little, if any, effect in lowering the transformation points. Cobalt steel therefore is not self-hard, but usually is of a perlite structure (soft). It has, however, a tensile strength rather higher than that of carbon steel, though scarcely comparable with that of nickel steel. The utility of cobalt as an alloy in high-speed steel remains to be shown.

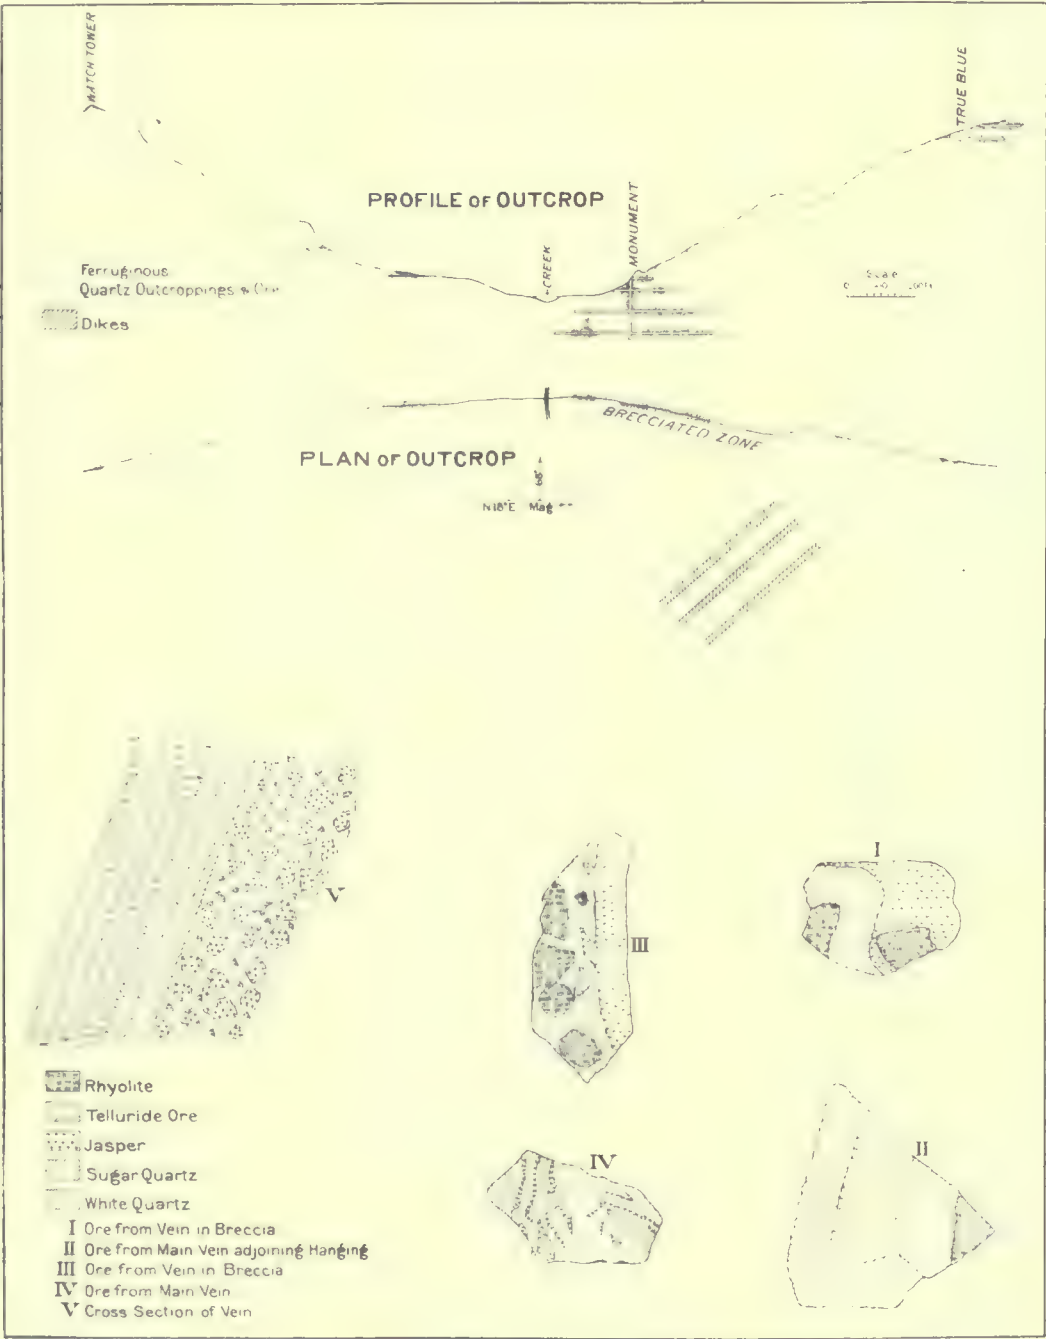

Drying ore-samples, according to instructions issued by the United States Steel Corporation, should be done as follows: "A portion of the entire sample, reserved for the moisture-determination, in either case not less than 2 kilograms, is transferred to a suitable pan and weighed, dried at 100° C. until constant weight is obtained, and the percentage of moisture calculated."

VEIN STRUCTURE IN THE MONUMENT MINE.

Written for the MINING AND SCIENTIFIC PRESS
By HENRY C. CARR.

The mines of the Oregon Idaho Co., which are the subject of this article, are situated in Lemhi county, Idaho. They are situated in the Salmon River mountains, a branch of the Bitter Root range, the latter being the dividing line between Idaho and Montana. The mines were originally discovered by Mexicans,

locality has been the scene of volcanic and thermal activity at a geologically recent period. The country rock for a distance of 12 miles, in either a north, east, or west direction, is an acid rhyolite of Tertiary age. This rhyolite flowed from a crater, one wall of which is situated about two miles south of the mine and still has an altitude of 10,000 ft. The various flows from the crater can be seen distinctly, as water-courses have eroded their way through the rhyolite to a depth of 1000 ft. below the present mine work-

The Monument Mine, Idaho.

who worked the rich surface ores in arastras, run by water-power on what is now known as Arastra creek, which traverses the property in a general east and west direction. Practically all the work has been done on the Monument mine (see map) and it is in this mine that exist the conditions to be described. The collar of the shaft is at an altitude of 6000 ft. above sea-level; the shaft follows the vein on its dip (69° from the horizontal) to a depth of 300 ft. The

ings. These flows follow a northerly direction and are of varying thickness, from 40 ft. upward. About two miles north from the mine is a cone of volcanic ash at least 500 ft. high and 500 ft. through at its base, while at a distance of half a mile west of the mine, intrusive dikes, thrusting their way through a hydrated volcanic sinter, have produced a fine quality of opal. The vein itself is an original fissure following a direction of N. 17° E. (Mag.) and was

caused by the cooling and fracturing of the rhyolite. The outcrop crosses the Watchtower, Monument, and True Blue claims of the Oregon Idaho Co. and is marked by high pillars of flinty quartz, so hard, that they have withstood the erosive action of the elements. It has an average width of 30 in. of banded structure, the bands being from 1 to 3 in. wide, very silicious (analyses, 96% SiO_2); it is a remarkable illustration of crustification. The ore occurs as bands, the valuable minerals being disseminated in minute particles through the gangue, in the form of telluride, petzite, and sylvanite. The ore shoots pitch to the north and the best ore (\$100 and upward) is found following the hanging wall. This hanging wall is smooth and shows no signs of any subsequent movement in any direction; neither is there any gouge, the rich ore being frozen to this wall so tightly as to become part of it, so that a slab from 1 to 3 in. thick has to be removed by moils. It seems that the ascending hot waters, following this open fissure, dissolved part of the hanging wall adjoining the fissure, and deposited silica in the form of quartz containing the precious metals, in the place of the soluble material leached out. Successive ascending solutions followed until the fissure was filled, some of these solutions being devoid of minerals of commercial value, as evinced by bands of broken white quartz. The monument mine has no foot-wall, while the Watchtower and True Blue mines on the same outcrop (see map) have two well defined walls. In the Monument mine for a distance of 400 ft. north of the shaft and 150 ft. south, on all the levels, there is found a brecciated zone from 40 to 100 ft. wide. This zone consists of pieces of blue jasper as large as a man's head, small fragmental pieces of high-grade ore from the size of a walnut to 3 in. diam., all cemented together by a barren sugary quartz, thoroughly disintegrated. This brecciated mass, on account of the small pieces of high-grade ore, assays about \$1.50 per ton, but is not of merchantable value. Cross-cuts into the breccia have demonstrated that there is no ore in it except feeders from the main vein; they are apparently offshoots of the vein and were caused by the ascending solutions following the line of least resistance along small fractures in the, then, foot-wall. The ore found in the feeders shows in every instance that it was not deposited along an open channel but as an impregnation and substitution of the country rock, because this particular ore invariably contains pieces of rhyolite, some of which is still fresh and some of it partly changed, as is shown by the sketch. To the east of the shaft and at distances of 300, 375, and 475 ft., respectively, are three rhyolite dikes having an average thickness of 40 ft. each. These dikes (see map) appear only on the north side of Arastra creek and run at an angle of 67° to the vein. If they continue below the surface as above they should cross the main vein at 800 ft. north of the shaft. They are very acid and erosion has failed to eliminate from the exposed sides the rough shearing scars showing where they were extruded through the country rock. As before stated, there are two walls in the Watchtower and True Blue mines, while the

Monument has a hanging but no foot-wall. On the first two mines, the width of the vein, its gangue, and assay-value are the same as on the Monument. The map also shows that the intrusive dikes do not appear except on the Monument claim. Is it not then right to reason that there was an original fissure, filled by subsequent recurring ascending solutions, and that the veins or feeders connecting with the main vein and found in the brecciated mass were caused by these same waters altering portions of the foot-wall rocks; that these intrusive dikes were subsequent to the vein-filling and were the cause of the brecciated condition of the foot-wall side. At the same time, did not the waters which accompanied these dikes as they were extended, produce the jasper and sugary quartz by metamorphism and leaching?

FRAUDULENT ASSOCIATION PLACER CLAIM.

A case of great interest, bearing especially upon Alaskan conditions, but also touching a fraudulent practice widely prevalent in the western United States has recently been decided by the U. S. Circuit Court of Appeals, 9th Circuit (*Cook v. Klonos*, 165 Fed., 529, Oct. '08), on appeal from Alaska.

The United States Mining Statutes authorize two or more persons to jointly locate placer claims. No such location shall include more than 20 acres for each individual claimant, and cannot exceed 160 acres, in which case an association of at least eight locators is required. Such an association claim of 160 acres was located in Alaska in the name of eight locators, six of whom were absent and residents of Ohio, and prior to making the location it was understood that Barnett, who held powers of attorney from the absent locators, and who was not himself a locator, was to receive half of their interest, or the equivalent of 60 acres. The Court of Appeals held that this understanding entered into the act of entry and location, rendering it fraudulent and void as against the United States. It is interesting to note the following language of the Court: "The mineral land laws of the United States are extremely liberal in the requirements under which possessory rights may be acquired. The few restrictions imposed are only intended to prevent the primary location and accumulation of large tracts of land by a few persons, and to encourage the exploration of the mineral resources of the public land by actual bona fide locators. The scheme of using the names of dummy locators in making the location of a mining claim for the purpose of securing a concealed interest in such claim appears to be contrary to the purpose of the statute; but when this scheme is used to secure an interest in a claim for a single individual, not only concealed but in excess of the limit of 20 acres, it is plainly in violation of the letter of the law, and when, as in this case, all the locators had knowledge of the concealed interest and were parties to the transaction, it renders the location void."

The cost of producing power in small gas-power plants in the neighborhood of 100 hp. is as low as can be secured in our largest and best steam central stations.

EIGHT-HOUR LEGISLATION IN NEVADA AND CALIFORNIA.

The subjoined statutes, modeled after the law of Utah, have recently been passed in Nevada and in California. The Nevada statute, as here printed, is official. The California bill given is from the copy introduced into the Assembly on January 15, which was passed and signed by Governor Gillett. The official statute has not yet been issued:

CALIFORNIA STATUTE.

An Act regulating the hours of employment in underground mines and in smelting and reduction works.

The people of the State of California, represented in Senate and Assembly, do enact as follows:

Section 1. That the period of employment for all persons who are employed or engaged in work in underground mines in search of minerals, whether base or precious, or who are engaged in such underground mines for other purposes, or who are employed or engaged in other underground workings whether for the purpose of tunneling, making excavations, or to accomplish any other purpose or design, or who are employed in smelters and other institutions for the reduction or refining of ores or metals, shall not exceed eight hours within any twenty-four hours, and the hours of employment in such employment or work day shall be consecutive, excluding, however, any intermission of time for lunch or meals: provided that, in the case of emergency, where life or property is in imminent danger, the period may be a longer time during the continuance of the exigency or emergency.

Sec. 2. Any person who shall violate any provision of this act, and any person who as foreman, manager, director, or officers of a corporation, or as the employer or superior officer of any person, shall command, persuade, or allow any person to violate any provision of this act, shall be guilty of a misdemeanor and upon conviction shall be punished by a fine of not less than fifty dollars (\$50) nor more than three hundred dollars (\$300), or by imprisonment of not more than three months. And the Court shall have discretion to impose both fine and imprisonment as herein provided.

Sec. 3. All acts and parts of acts inconsistent with this act are hereby repealed.

NEVADA STATUTE.

An act to regulate the hours of employment of working men in open-pit and open-cut mines, so as to better protect the health and safety of those engaged in such work or occupation, and providing penalties for the violation thereof.

(Approved, March 5, 1909.)

The people of the State of Nevada, represented in Senate and Assembly, do enact as follows:

Section 1. The period of employment of working men in open-pit and open-cut mines shall not exceed eight (8) hours in any twenty-four (24) hours, except in cases of emergency where life or property is in imminent danger.

Sec. 2. Any person who violates any provisions of

section one of this Act, or any person, persons, corporation, employer, or his agent, who hires, contracts with, or causes any person to labor in any open-pit or open-cut mines, for a period of time longer than eight (8) hours within any twenty-four (24) hours, except in cases of emergency where life or property is in imminent danger, shall be guilty of a misdemeanor, and upon conviction thereof shall be punished by a fine of not less than one hundred dollars (\$100) nor more than five hundred dollars (\$500), or by imprisonment in the county jail for not more than six months, or by both such fine and imprisonment.

Sec. 3. This Act shall take effect thirty days from and after its passage.

Spelter-production for 1908 was as shown by the following table:

Locality.	Tons.	
UNITED STATES:	1907.	1908.
Arizona	77	152
Arkansas	1,911	2,002
California	140	27
Colorado	26,077	24,885
Idaho	3,508	581
Illinois	1,446	298
Iowa	220	516
Kansas	13,850	8,628

New Jersey	13,573	6,926
New Mexico	136	134
Oklahoma	719	2,235
Tennessee	181	341
Texas	16
Utah	1,972	282
Virginia	771	910
Wisconsin	15,273	17,538
Total domestic	223,745	190,749
FOREIGN:		
British Columbia	545	2,425
Mexico	25,570	17,250
Total foreign	26,115	19,675
Grand total	249,860	210,424

The production of spelter for the world in the year 1908 was 799,644 tons of 2000 lb., being a decrease from 813,842 in the previous year. Belgium stood next to the United States, contributing 181,910 tons. The third place was taken by Silesia with 158,379 tons.—U. S. Geological Survey.

Contact deposits are the chief producers of copper and iron in Mexico. The great copper mines at Cananea belong to this group, as well as most of the orebodies in the Sierra Madre Occidental, and of the interior and northern portions of the Mesa Central. While the larger portions of these deposits yield copper or iron, yet many yield lead or zinc, even of gold in association with copper. Good illustrations are furnished by San Carlos in Tamaulipas, Sierra del Carmen, Golondrinas, Mazapil, Encarnacion, Las Vegas, Aurora, Balsas, Cerro de San Pedro, and Campo Morado.

DISPOSAL OF GOLD FROM THE RAND.

By T. KIRKE ROSE.

*By common consent, statistics are admitted to be both misleading and dull, and the following account of the first rough distribution of the gold produced in South Africa cannot be expected to escape the common lot of such papers. Consequently I beg the Society to remember that the paper was written at the invitation of the Council, following a suggestion made by T. L. Carter. In drawing up this account I have used official publications only and have everywhere reached the limits of information almost at the beginning of the enquiry. My own private quarrel with statistics is not that they are misleading and dull, but that they always stop short before they have told what I want to know, so I am continually driven to making guesses.

The official publications consulted are the Annual Statements of Trade of the United Kingdom, the Statistical Abstracts of the United Kingdom, and of the British Colonies, Possessions, etc., and the Annual Reports of the English, French, and United States Mints.

I have considered only the period of five years, 1903 to 1907,† because during the war the production of gold in South Africa was comparatively unimportant, and the years 1899 to 1902 were abnormal in that and other respects. In a limited sense every year is abnormal. The conditions affecting the distribution of gold change continually, and it is useless, from a study of statistics alone, to hazard predictions.

At the beginning of the study of what becomes of the Rand gold, it must be premised that no distinction can be drawn between the gold from the Rand, and that from other districts. The gold from the Rand goes down to the coast and is at once, statistically speaking, mingled inextricably with that from the rest of the Transvaal and from Rhodesia. The combined stream flows into London, and there joins other streams, and its identity is lost again. Little rills flow out hither and thither and are caught up in other currents, so that by imperceptible degrees the whole world is involved. In this paper the assumption has been made that wherever two streams unite and become indistinguishable from each other, they are at once completely mixed, so that any sample, however small, contains the same proportion of each constituent as the whole mass.

When the Rand gold leaves South Africa, a slight difficulty is at once encountered, for no definite statement is available as to its destination. The declared value of the production of gold in the Transvaal and Rhodesia was, for example, £26,615,025 in 1906. The value of the exports of gold from British South

Africa is given as £26,516,475 for 1906 in the Statistical Abstract. In the Annual Statement of Trade of the United Kingdom the value of the gold bullion imported into England from South Africa is not given, but only the gross weight in ounces, for example, 6,986,832 oz. in 1906. The result is that the imports into the United Kingdom cannot be identified with the exports from or the production of British South Africa. These three figures are, however, in sufficient agreement (taking the mean gold-fineness of South African bullion imported into England as 875) to justify the assumption that practically all the South African gold is exported to London. Apart from the figures, this is, of course, perfectly well known.

On arrival in London the South African gold is mixed with bullion coming from other parts of the world, and can no longer be distinguished. This matters the less for the reason that the South African bullion forms the bulk of the total imports of gold bullion, as is shown in the following table, drawn from the Annual Statement of Trade for 1907:

IMPORTS OF GOLD INTO THE UNITED KINGDOM.

	1905.	1906.	1907.
Country of Origin.	troy oz.	troy oz.	troy oz.
British South Africa..	5,833,741	6,986,832	8,012,437
British India	610,320	571,033	547,452
Australasia	972,342	729,237	803,961
Rest of world.....	664,828	805,703	1,334,608
Total oz.	8,087,231	9,092,805	10,698,458
Total value	30,114,369	33,865,361	39,956,304
Gold-fineness	876.6	876.8	879.2

In these years South African gold is seen to form 72, 71, and 75% respectively of the total weight, and judging from unofficial returns, the values were in nearly the same proportions. The bullion on arrival in London is in part refined there and in part re-exported in its unrefined state. Beginning with 1908, the Customs Establishment will publish statistics distinguishing between unrefined and refined bullion imported and exported, but no figures are as yet available. My own opinion is that about 15% of the imported bullion was re-exported in the period 1903 to 1907, without being refined in London. Both the amount and the percentage of such bullion appear to be increasing, but there is little to go upon in forming these opinions. The refined bullion is partly retained in the country and partly exported. Comparison of the total imports and exports of bullion shows:

	1903-7.	1907.
Imports	£151,973,235	£39,956,304
Exports	98,059,568	26,589,442
Excess imports	£53,913,667	£13,366,862

Here the imported bullion is divided clearly into two parts, one part required and retained in the United Kingdom, while the other part is re-exported without delay. These will now be considered separately.

Dealing first with the bullion retained in the United Kingdom, it is at once evident that most of it is converted into coin, thus:

	1903-7.	1907.
Coinage from ingots only at the		
Royal Mint, London	£48,944,370	£16,098,894

*Paper read before the Chemical, Metallurgical and Mining Society of South Africa, February 20, 1909.

†Difficulties with this period were encountered owing to the fact that the latest U. S. Mint Report issued is for the year ending June 30, 1906, and the latest French Mint Report is for the year ending December 31, 1906. Some of the figures given in these reports extend only to the end of 1905. The Statistical Abstracts come down to the end of 1906 only.

Some of the ingots received for coinage, however, are derived from the melting of gold coin. No exact record is kept of the value of these, but, in my opinion, it may be put at the following amounts:

	1903-7.	1907.
Ingots resulting from melting gold coin.	£1,392,000	£4,500

The coinage from refined ingots at the Royal Mint has accordingly been approximately as follows:

1903-7.	1907.
£47,552,400	£16,094,400

The rest of the bullion retained in England but not used for coinage, which amounted to about £6,361,300 for the five years 1903 to 1907, was added to the stock of bullion already in existence, or was used in the arts for the manufacture of jewelry, for gold plating, for the manufacture of gold leaf, in dentistry, in photography, and so forth.

The stock of bullion in the United Kingdom, apart from the floating stocks held by refiners and bullion dealers, is in the vaults of the Bank of England. No figures are available as to the amount so held, the Bank making known only its total stock of bullion and coin. The stock of bullion is, of course, a fluctuating amount, but any gradual permanent change is doubtless in the direction of an increase. The gold bullion and coin held by the Bank on December 31, 1902, was £27,840,385, that on January 2, 1907, £29,270,470, and on January 1, 1908, £31,602,515. For purposes of comparison, it may be remarked that the mean stock in the first week of January of the ten years 1881 to 1890 was £20,550,000. It is likely that a part of the increase shown was in the form of ingots. During the year 1907, it is quite possible that the stock of bullion was reduced.

Leaving all this on one side, therefore, we have the sum of £6,361,300 in ingots, which was all or mostly used in the industrial arts in the United Kingdom during the years 1903 to 1907. No estimates of the consumption of gold are published officially in England, though the matter will doubtless be dealt with in the forthcoming Census of Production. The total consumption for the three years 1903 to 1905, however, has been estimated by the Director of the U. S. Mint* at £7,706,000, excluding old material (re-melted jewelry, etc.), but including gold coin. This seems to me, judging from returns of the manufacture of jewelry to which I have had access, to be a reasonable figure, but the annual consumption in 1906 and 1907 was certainly higher than from 1903

1905. The amount of English gold coin melted for use in the industrial arts is estimated at £100,000 at least,† its only known use being for the manufacture of wedding rings. This would leave an annual amount of about £2,000,000 to be derived from gold ingots or £10,000,000 in five years. There is here a discrepancy of nearly £4,000,000, which is most readily accounted for by assuming that the

amount of British gold coin melted for use in the arts was underestimated in 1903, and that it really amounts to £1,500,000 per annum. The disappearance of immense quantities of British gold coin has certainly never been fully and satisfactorily explained. The discrepancy would be equally well accounted for by the assumption that £1,000,000 in gold coin is melted down annually in the United Kingdom and subsequently exported.

The destination of the exports is shown in the following table, which is abstracted from the Annual Statements of Trade for 1903 to 1907:

Countries to which exported.	1903-7. troy oz.	Per cent.	1907. troy oz.	Per cent.
Continent of Europe.	13,005,963	54.4	2,021,561	30.4
United States	6,063,671	25.3	3,143,700	48.1
British India	4,630,381	19.3	1,374,879	...
Rest of world.....	227,822	1.0	1,272	21.0
Total oz.	23,927,837		6,541,402	
Total value	£98,059,568		£26,589,442	
Gold-fineness	964.8		956.9	

Concerning these tables it may be observed that 'Europe' stands chiefly for France and Germany, which together take almost the whole of the exports in certain years. There are exceptional years, however, as for example 1906, when 402,559 oz. went to Russia, as against 1,140,537 oz. to France, and only 77,068 oz. to Germany.

The gold bullion imported into France for the most part stays there, the exports of ingots being inconsiderable. The bars from England form over 30% of the total imports of gold and over 40 of the imported ingots. About one-half of the imported bar gold is coined, chiefly into 20-franc pieces; about a quarter of it is employed in the industries; perhaps 5% is re-exported, and the remainder presumably goes to swell the stock of bullion in the Banque de France, which increased by about £16,000,000 in the four years 1903 to 1906.

Of the gold bullion imported into Germany, something like 20% is re-exported, a like amount is used in the industries, and the remainder is coined. The gold ingots sent to America have varied in amount more than those exported elsewhere. From 1903 to 1907 (the year of the panic) they increased steadily from 158,945 oz. to 3,143,700 oz. There was, of course, a large reduction in 1908. The mean for the five years from 1903 to 1907 amounted to over 10% of the gold deposited at the U. S. Mints. Of this total quantity, in the years 1903 to 1906, about 55% was coined, about one-seventh was used in the industrial arts, and the remainder was added to stock or exported. According to the U. S. Mint Reports, however, the ingots exported are almost invariably United States fine bars, practically never foreign ingots. Also rather more than 40% of the imported gold bars were issued for use in the industrial arts in the years 1903 to 1905. This would leave nearly 60% of the imported bars to be divided between coinage and additions to the stock of bullion in the U. S. Mints and Assay Offices. This stock is subject to great fluctuations: for example, it was \$124,083,823 on June 30, 1902, \$51,910,029 on June 30, 1905, and \$104,383,158 on June 30, 1906. No exact informa-

*These figures are taken from the Annual Report of the Director of the French Mint. They are stated by him to be quoted from statistics published in Washington on authority of the Director of the U. S. Mint, but they do not appear in the Annual Report of the U. S. Mint.

†Annual Report of the Deputy Master of the Royal Mint, London, 1903, p. 22.

tion is available as to the stocks on January 1, 1903, and December 31, 1907, and it is better to leave this aside, as in the case of the stock of bullion in the Bank of England, and to assume that 60% of the imported bars was used for coinage. The difference between the percentage distribution of the total deposits in U. S. Mints and the distribution of the imported gold bars (of which those from England form only a part) illustrates the difficulties of this part of the enquiry, and shows how great may be the errors in the statements as to the disposal of the gold exported to France and Germany.

The gold bullion (chiefly or entirely in the form of 10 oz. fine bars) which is sent from England to India, disappears on arrival in that country, and is probably in great part converted into jewelry. As the Director of the U. S. Mint remarks, "The tide of gold and silver has been flowing into India for centuries." Probably some large hoards exist, but, no doubt, there are immense numbers of small hoards. From 1835, when the official records begin, the net imports to the end of 1906 amounted to £193,880,000, in addition to the production in India, which was £23,400,000. The world's production for the same period is estimated at £1,920,000,000, approximately 12% of which was accordingly absorbed by India.

The wanderings of the gold bullion from the Rand have now been traced as far as is practicable. Summarizing the disposal of the Rand gold for the period 1903 to 1907, the following seems to be shown:

	Per cent.
Used in coinage.....	58.6
Used in industrial arts.....	30.5
Deposited as ingots in the Bank of France.....	3.5
Undetermined	7.4

The result may also be put in the form of a bet: such as that of any particular ounce of gold produced on the Rand, it is 7 to 1 against its disappearing into India as refined 10-oz. bars, 99 to 1 against its being exported from France to an unknown destination, and 69 to 31 against its being coined at the Royal Mint.

The Trans-Siberian railway up to the end of 1903 had cost \$172,525,000. From motives of economy it was laid out as straight as possible, passing 45 miles to one side of the large and important city of Tomsk, while the cities of Tcheliabinsk, Kurgan, and Omsk are all from 1 to 6 miles from their respective stations. The station of Irkutsk is separated from the city of that name by the broad river Angara. Save for the bridges over the rivers and the tunneling around the southern end of Lake Baikal, no special technical difficulties were encountered in building the Trans-Siberian railway; in fact, those tunnels around Lake Baikal are, with but one exception, the only ones on the whole line. Since the war, traffic on the railway has greatly increased, making it one of the greatest highways of world-commerce. Through tickets to points in the Far East by way of the Trans-Siberian are now sold at all the principal European cities, and at several places in the United States. The journey between Vladivostok and Irkutsk takes four and a half days, and between Mos-

cow and Irkutsk six and a half days, making eleven days between Vladivostok and Moscow. The journey between Vladivostok and Harbin takes 36 hr., and Peking may be reached in eighteen or nineteen days from the chief European capitals by rail. In addition to the regular Government bi-weekly Trans-Siberian express, an international 'train de luxe' is run weekly. The most important branches of the Trans-Siberian railway are those between Taiga and Tomsk, about 45 miles in length, built to connect Tomsk with the main line of railway, and from Karamskaia to Stretensk on the river Shilka, which it is proposed to continue along the Amur to Blagovestchensk and Kharbarovsk, giving Russia a trans-Asiatic railway entirely in her own territory. Nearly 200 miles of this railway is in working order, but it will be four years before it can be completed. The railway from Mikolskoe to Khabarovsk, in the Primorskaya, or Maritime Province, is 474 miles long, and is of great strategic and commercial importance.

Cyanide Poisoning.—In the Melbourne *Argus*, a writer, Orme Masson, of the Melbourne University, draws attention to the sad death by cyanide poisoning of Charles Robertson, battery-manager of the Birthday mine, Berringa, and says this is not the first time by any means that a thirsty man has thoughtlessly swallowed the contents of a beaker standing ready to his hand on the laboratory bench, and then realized, too late, that it was not water but deadly poison. "And," adds the writer, "it is certain that such accidents will happen again, and that each will cause the loss of a valuable life unless the risk be publicly recognized and counteracted. The risk arises in the first place from the fact that cyanide solutions look exactly like water. The addition of a small amount of a suitable coloring matter would be the best precaution were it always practicable, but it could not be insisted on in a laboratory. Failing such obvious methods of prevention, it is surely desirable that means of cure should be kept at hand wherever an accident is possible; and, as this can be very simply done, it appears to me that proprietors of works should be compelled by law to do it. Seven years ago the Victorian Government evidently contemplated some action of the sort, for they commissioned Dr. C. J. Martin, then professor of physiology in the Melbourne University, to investigate and report upon the antidotes for cyanide poisoning. Their experiments led me to reject certain reputed antidotes on the score of inefficiency or danger, and to strongly recommend the following mixture: 1 oz. of 23% solution of ferrous sulphate, 1 oz. of 5% solution of caustic potash, 30 grains of powdered magnesium oxide. There is every reason to believe that this mixture will prove an effective antidote if administered at once, but a very few minutes' delay must prove fatal. Martin and O'Brien therefore recommended that the materials be kept in sealed tubes which can be broken at a moment's notice, the tubes and a suitable mixing vessel to be conspicuously placed wherever they may possibly be wanted."—*Queensland Government Mining Journal*.

MINING AND METALLURGICAL PATENTS.

MEANS FOR CHARGING THE RETORTS OF ZINC AND OTHER ANALOGOUS FURNACES.—No. 914,339. Emile Dor-Delattre, Liege, Belgium.

In an apparatus for charging the retorts of zinc or similar furnaces, the combination of a hopper, a motor, a conveyor comprising two rotary disks connected by a series of blades adjacent their peripheries, one of said disks being connected with the shaft of the motor, a casing surrounding the conveyor, a delivery chute communicating with the casing, and a conduit extending from the hopper through openings in the casing and one of the disks of the conveyor.

CABLE-GRIP.—No. 911,460. Thomas W. Tiley, Bellingham, Washington.

A cable grip comprising a body composed of separable sections and having a passage for the reception of a cable, a lever pivoted within said body and arranged to grip the cable, means for securing the sections of said grip about a cable, comprising a reversible member, whereby said grip may be locked or detachably secured about the cable when a load-attaching member is connected to said lever.

AMALGAMATOR.—No. 913,902. Louis C. Laurent, Denver, Colorado.

An amalgamator comprising a solid table whose upper surface is provided at intervals with mercury-containing recesses or pockets, a central longitudinally disposed rib dividing the surface of the table into two compartments, the lower extremity of the table being provided with many recesses and pockets which extend the entire width of the table, the whole being composed of a solid unitary mass of glass.

INTERNAL-COMBUSTION ROCK DRILL. No. 915,893. Lewis L. Scott, Joplin, Missouri.

In a device of the kind described, a cylinder, a piston, a drill rod carried by the piston and working through an end of the cylinder, a ratchet rotatable loosely upon said drill rod and within the cylinder, a screw carried by the cylinder

head and extending inwardly beyond said ratchet, a projection carried by said screw loosely engaging the inner face of the ratchet, a pawl pivoted by said screw and engaging the ratchet teeth, a casting forming an extension of the hub of the ratchet and extending inwardly toward the piston and inclosing a portion of the drill rod, said rod having a spirally arranged groove formed on the portion inclosed by said extension and at a distance from the ratchet, and means carried by said extension for engagement with said groove, said means being arranged adjacent the inner end of the said extension and at a distance from the said ratchet, as and for the purpose set forth.

APPARATUS FOR ROASTING AND SINTERING ORES.—No. 916,392. Arthur S. Dwight, Joliet, Illinois.

An apparatus for roasting and sintering ore by combustion in the ore mass, the combination of an endless ore support or carrier having an annular flat grate surface on which the ore rests arranged in a horizontal plane, means for turning the grate surface about a vertical axis, and means for supplying air to support combustion in the ore mass, substantially as set forth.

PROCESS OF ROASTING AND SINTERING ORE.—No. 916,396. Arthur S. Dwight, Joliet, Illinois.

The process for treating ores or metal bearing materials containing combustible elements, which consists in causing a layer or stream thereof to move continuously in one direction, igniting the combustible elements of the ore along one of the surfaces of the said layer or stratum, applying to the said surface a supporting or retaining device adapted to move therewith, delivering to the said surface air or combustion supporting gas, applying to the opposite surface of the layer or stream a supplemental retaining device adapted to restrain the particles of ore from agitation or disturbance, and causing the escape from the last said surface of the gases of combustion or reaction, substantially as set forth.

APPARATUS FOR ROASTING AND SINTERING ORES.—No. 916,391. Arthur S. Dwight, Joliet, Illinois.

In an apparatus for treating ores, substantially as described, the combination of a movable ore support adapted to carry a bed or layer of ore, air inducing apparatus on one side of the ore support adapted to cause currents of air to pass through the ore mass, and a hood or reflector for the heat arranged adjacent to the ore mass and substantially parallel with the line of travel thereof and on the side of the ore support opposite the said air inducing apparatus; also means for supplementally feeding a layer or stream of material to the support in contact with the layer or stream of ore, substantially as set forth.

GEOLOGY OF THE GOLDFIELDS OF BRITISH GUIANA. By J. B. Harrison. 8vo., pp. 320, Ill., Appendices, Index. Published at the Direction of the Government of British Guiana by Dulau & Co. London. 1908.

The coast of British Guiana is a low alluvial plain, traversed by lines of sand dunes. The marine alluvium has been proved to depths of over 200 ft. From some of the bore-holes gases, particularly rich in methane, were given off in large quantities, and in a few cases petroleum was found. This petroleum is manifestly of extremely recent origin. British Guiana occupies one of the most stable areas of the earth's surface, which has for ages been free from volcanic disturbance, although it has been slowly rising, thus resembling Atlantic Coast conditions in the United States, where the streams are navigable only a relatively short distance from the sea before rapids are encountered. Here the rocks of the country are first found. The interior of British Guiana is covered to a large extent with sand stones and conglomerates, through which are many dikes of diabase, which occurs chiefly in belts, striking from northwest to southeast, constituting important mountain masses in the Eagle mountains in the Potaro gold-field. The clastic deposits previously mentioned constitute the greater part of the Pacaraima mountains, and spread westwardly into Venezuela. Similar rocks are found in the State of Amazonas, Brazil, extending as far south as Obidos, on the river Amazon. These deposits are referred to the Cretaceous, and that proves the diabase intrusives to be probably Tertiary. Granites are sparingly found, these containing black mica, partly replaced by hornblende, with relatively abundant triclinic feldspars. Beautiful exposures are found at the Palwori-Cayra rapids on the Essequibo river. Through a large part of the Colony are also found quartz-porphyrries, felsites, and sericite schists, which have to a great extent been chloritized. The fundamental geologic complex of British Guiana consists of gneissoid rocks, including epidiorites and hornblende schists, quartz diorites, amphibolites, and altered gabbros. These have all been subjected to dynamic metamorphism, converting them into foliated rocks. There is great complexity in the strike of the foliation. The work before us gives an admirable review of the geologic history of the area under consideration, which will be of great service to anyone interested in the geology of the whole of northeastern South America. The petrography of the country is the subject of a number of interesting chapters, handsomely illustrated. Indeed, the book is lavishly illustrated throughout with beautiful art-type reproductions in sepia. These reveal not only the geology, but the mining methods, and the general scenery. The gold-bearing veins are mostly of quartz, locally called 'reefs', occurring for the most part where the country consists of gneiss traversed by belts of epidiorite, or of hornblende or chlorite schists, through which numerous intrusions and outbursts of diabase have taken place. The chief districts are the northwestern, near Arakaka; the Cuyuni River, Mazaruni-Puruni, Essequibo, Potaro, and Demarara. The accounts of the occurrences given by Mr. Harrison are extremely full, and will be of great interest. He accepts J. E. Spurr's explanation of the origin of the gold deposits of Guiana, only to a limited extent, as applying to the Omai district, but not to such as those in Potaro, Puruni, and Cuyuni. Spurr held that the gold ores in British Guiana represent one of the closing phases of the great granitic intrusions, and that the basic dike-rocks, with which the gold-ores are associated, as well as the silicious dikes with which they are also related in many places, are representatives of the general process of granitic intrusion, earlier than the veins but subsequent to the main intrusion. A great many of the alluvial concentrations have apparently come from solution of the gold in the waters of the soil-covering, and re deposited in laterite and ironstones. The

evidence of this remarkable process is given in detail and with great conclusiveness. Among these proofs is offered the result of experiments with woods grown on the laterite deposits, in which the ash of the bark, constituting 4.78% of the original weight, yielded on assay one grain of gold per ton, while the ash of the wood, representing 0.67% of the original weight, assayed from 7 to 10 grains per ton. There is a chapter on the diamantiferous areas of the colony. The diamonds are found mostly in gravel deposits, but have also been discovered in residual soils from the decomposition in place of gabbro and diabase. These were mostly very small, averaging about one fiftieth of a carat. The volume contains historical chapters by Frank Fowler and C. Wilgress Anderson, with an appendix giving the laws and regulations governing the mining industry in British Guiana.

ECONOMIC GEOLOGY OF THE GEORGETOWN QUADRANGLE, COLORADO. By J. E. Spurr and G. H. Garrey, with GENERAL GEOLOGY by S. H. Ball. U. S. Geol. Sur., Prof. Pap. 63. pp. 423. plates, figures, and maps. 1908.

The Georgetown quadrangle includes a portion only of Clear Creek and Gilpin counties in Colorado. Nevertheless this is much the most complete report available on these old and famous mining areas. Mr. Spurr wisely refused to be bound by the artificial limits of the quadrangle and has discussed the geology and ore deposits of the region in their broader relations. Indeed, the report deals, in outline, with the ore deposits of Colorado as a whole, and will serve a useful purpose in that connection. The rocks of the area, with the exception of porphyritic dikes of probable Tertiary age, are considered to be pre-Cambrian in age. The oldest gneisses and schists are believed to have resulted from the metamorphism of a sedimentary series. These have been folded, sheared, and injected by a series of granular pre-Cambrian igneous rocks. The veins are divided into silver-bearing, predominant near Georgetown, and gold-bearing, found mainly around Idaho Springs. The former are believed to be related to veins occurring in a great belt from Boulder county, through Georgetown, Leadville, and Aspen, to the San Juan. Throughout this belt the ore deposits have many common features, including particularly relationship to monzonitic intrusives. Contrasted with them are the gold-bearing veins, most of which are connected with isolated volcanic eruptions. Silver Cliff and Rosita, and Cripple Creek are the best known examples.

The argentiferous silver-lead deposits within the Georgetown quadrangle contain chiefly galena, blende, and pyrite, with quartz as gangue. Probably the gangue-minerals are derived from the wall rocks, and a large part of the vein-material is immediately due to precipitation from ordinary surface waters. The original derivation of the metals is not shown by this study. The primary deposits consisted of predominant blende, with galena and pyrite. These were laid down through a considerable vertical range. The veins have been actively eroded, and descending waters have enriched the upper portions. The veins now exposed represent enriched roots, or secondary veins formed below the original root.

The auriferous veins consist essentially of pyrite with quartz gangue. The pyrite contains gold with copper and silver. Galena and blende are present in varying quantity. Their deposition closely followed the intrusion of certain dikes containing fluorite, and representing the pneumatolytic stage. It appears probable that these mineralizing waters and the contained gases were of magmatic origin. The hot springs at Idaho Springs have also been studied. It appears probable that the bases in solution are derived from dissolution of the wall rock. The acids are regarded as having been given off from portions of the alkaline syenitic magma, still cooling in depth. The water is regarded as of magmatic origin.

EDITORIAL.

FRAUD ORDERS have been issued by the Postmaster General, forbidding delivery of mail or payment of money orders to W. W. Degge, and the various Wellington companies of Colorado. Thus the field of opportunity for making mushroom millions is ruthlessly restricted.

COPPER-STOCKS are estimated to exceed 182,000,000 pounds, which is 18 per cent of the total annual production for the United States. The contribution for the month of March to this surplus was approximately 8,350,000 pounds, which was 7.5 per cent of the total monthly output. It is evident, therefore, that the stocks of marketable copper are not accumulating at an increasing rate.

WHAT the public thinks of the great financial leaders is shown by the heavy oversubscription of the \$10,000,000 of stock in the International Smelting & Refining Company. Regardless of affiliations which have been condemned from ocean to ocean, and warned by graphic tales of the gentlemanly highwaymanship of some of the leading figures, the public believes that success lies in the company of the successful; and as soon as the stock was quoted on the Curb it leaped to 140. Those who wished to make a quick turn surely were rewarded for their faith.

IMPROVEMENT in railway earnings in New England has peculiar significance. Industrially this region stands between the producer of raw material and the consumers of finished products. An essentially manufacturing community, it plays in the economic world somewhat the rôle of a hydraulic equalizer. Hence rise and fall of the level of its trade indicate widespread tendencies. The New York, New Haven & Hartford Railroad Company has announced that the earnings during the last nine months have recouped the losses for an equal period in 1907. The only point where depression appears to be persistent is in the brass-manufacturing district of Connecticut.

BROKEN HILL, with its great reserves of ore, has been something of a menace to lead and zinc producers of recent years. According, however, to the testimony of G. D. Delprat before the Federal Arbitration Court at Port Pirie, there are only two and three-quarter million tons left in the Proprietary mine. Production has recently been at a rate of five hundred to six hundred thousand tons. It is clear that at this rate the known reserves will be quickly exhausted, and Mr. Delprat does not expect any appreciable additions to be discovered. The ore averaged 13.35 per cent zinc, 13.3 lead, and 11.3 ounces silver for the first half of 1908. Government

estimates made in January 1907 give a total reserve of more than seven million tons held by seven other Broken Hill companies. Against this must be offset the production since that date.

STANDARD OIL met a worse rebuff than was administered by Judge Landis when the New York Curb demanded full financial statements from companies whose stocks are there listed. It is possible that an invidious distinction would be made? Specific differences in the breeds of the devouring beasts should not dispose the public to indulge the appetite of the cormorant to the exclusion of the wild-cat.

ADENVER OFFICE of the U. S. Geological Survey is to be established that will form a permanent Western headquarters. This marks a return to certain older plans and ideals, and is a welcome announcement. When, in earlier days, Emmons and Cross made their headquarters at Denver, and the Colorado Scientific Society met in the Survey office, the personal contact between the officers of the Survey and the practicing engineers was constant and helpful. An office there now ought to be even more beneficial, but to realize the full benefit of the plan it will be necessary to detail a certain number of high-grade men under an officer of real influence having some independent authority. Helpful as it will be to have in the mining region a supply of documents available for prompt shipment, and much as it will facilitate public business to have a local paymaster and a force of clerks, something more is needed. The West requires closer contact with the Survey, and the Survey has something to gain by more than a summer's contact with the West. We extend congratulations to the Director.

Lanyon Zinc Failure.

Appointment of a receiver for the Lanyon Zinc Company just now may have an important influence on tariff legislation. This company has been one of the larger importers of ore, and was one of the pioneers among Kansas smelters in using Western zinc ores. The application for a receiver is a concrete and appealing bit of evidence that the margin in zinc smelting has been growing narrower. The low price of metals, and the changes in customs regulations, have been particularly severe on this company, since it is more of a buyer than a producer of ore. Its business in recent years has consisted largely in handling low-grade material containing precious-metal residue. It is said that no interest has been paid on the bonded debt since 1905, and that the amount now due is \$483,000. The Lanyon Zinc Company was formed in 1899 by consolidation of the Robert Lanyon Sons Smelter Company, with plants at Iola and La Harpe, and the W. & J. Lanyon works at Iola and Pittsburg, Kansas. Eastern capital was brought into the business and, under the management of Mr. Joseph Cappeau came the long and bitter litigation over the Brown-Ropp furnace patents and the resulting development of the Cappeau furnace. It will be recalled that the Lanyons themselves have been connected with American zinc-

smelting from the early days. Robert Lanyon was one of the pioneers at Mineral Point, Wisconsin, and began work when Matthiessen, Hegeler, and the Jones brothers were laying the foundation of American zinc-smelting. Later Lanyon operated at La Salle, Waukegan, and at various points in the Missouri-Kansas district. At first coal-fired furnaces were employed, but after 1895 gas was used. The Lanyons were, in fact, the pioneers in using gas for zinc-smelting in the Kansas field, but with this exception the family has not been noted for its contributions to technical progress. In general they have been shrewd traders; builders of furnaces which after a while have usually been sold to the 'trust' dominant at the time. The Waukegan works were sold with good profit to the Mineral Point Zinc Company, and when in 1896 the Cherokee-Lanyon Zinc Company was formed, the family got rid of a number of small coal-fired smelters and began building in the gas belt. Certain of the Lanyons are now interested in building up a zinc-smelting industry at Bartlesville, Oklahoma. Doubtless in time the new furnaces will be ready for consolidation and sale. Meanwhile the Eastern stockholders of the present Lanyon Zinc Company, beset by difficulties on all sides, and with no interest since 1905, can hardly be blamed for having failed so opportunely.

Farmer v. Miner.

Agriculture and the mineral industry are contentious consorts. Mr. Daniel Guggenheim is reported to have recommended to anyone seeking the excitements of litigation, that he establish a smelter in a farming community. The problem of stream-pollution is becoming as serious as that of smelter-smoke. To the famous *débris* cases of California, the Highland Boy Gold Mining case in Utah, and that of the Bunker Hill & Sullivan in Idaho, is added the Arizona Copper Company Limited *v.* Gillespie, just decided by the Supreme Court of Arizona. Gillespie in a test case sued for and obtained a perpetual injunction. He was the owner of 267 acres of alfalfa land in the upper Gila valley; agriculture was being conducted under like conditions on 23,000 acres, dependent upon irrigation for productivity. Ranching and mining were begun simultaneously in 1872. In 1882 a concentrator was erected, throwing its refuse into San Francisco river and Chase creek, tributaries of the Gila above the town of Morenci. The pollution of the stream caused serious damage during the season of low water. The slime and slickens from the concentrator formed an impermeable crust over the soil, choking the growth of vegetation. The respective populations interested were 8000 dependent upon agriculture and 12,000 upon mining, while the disproportion between the capital invested was even greater. The decision was a victory for the farmer.

Three great principles seem to be on trial. These are the utilitarianism expressed in the doctrine of "the greatest good to the greatest number;" the principle of the inviolability of private right; and, by implication, the question of practically unrestricted application of the right of eminent domain.

It is conceivable that we may be at the parting of

the ways. Two courses of development lie open, as they did to the onward and upward growth of life; the skeleton may cling to the exterior as a restricting envelope and lead to a well methodized ant-hill, or it may retreat within and leave a flexible organism having no narrower limitations than the universal dominion of the human intellect. The question is—which represents the flexible course of progress, and which the repressive crust, in the social evolution? If the law insists upon the exaltation of the unit, the mass should logically become a body of exalted units; if the stress be laid upon mankind collectively—who knows what will become of the unit, and who can predict the character of the social result? No questions of more serious import rest upon us for decision; furthermore, without being able to properly weigh the consequences, we are deciding these questions daily, and our judges are giving interpretation to the laws that will crystallize custom from which there can be no escape.

The cleavage between the two phases of judicial thought touching the question is sharp and clean. The Arizona Court has held to the viewpoint of the California and Utah benches, proclaiming the indefeasible right of the individual. The principle of comparative injury set forth in the *Mountain Copper*, the *Bunker Hill & Sullivan*, and the *Anaconda* cases was flouted, and the language of Judge Sawyer (*Woodruff v. North Bloomfield Gravel Mining Company*, 18 Fed. 753) was quoted with approval: "It is by protecting the most humble in his small estate against the encroachments of large interests that the poor man is ultimately to become a capitalist himself;" and again, the rule laid down in *McCleery v. Highland Boy Gold Mining Company* (140 Fed. 941) was re-affirmed in the words, "public policy is more concerned in the protection of individual rights than in the profits to inure to individuals by the invasion of those rights." Finally the Arizona Court declares as its independent view that "to withhold relief where irreparable injury is and will continue to be suffered by persons whose financial interests are small in comparison to those who wrong them, is inconsistent with the spirit of our jurisprudence."

That is certainly true of the historic spirit of our jurisprudence. We cannot conceive Chief Justice Marshall ever entertaining the contrary opinion. It was through accentuation of the right of the individual that liberty and progress led up to the founding of the free institutions of the New World. The subduing of a continent was achieved under the inspiration of men filled with the self-reliant manhood that comes from magnifying the importance of the individual. The complexities of modern industrial growth have led in later years to a sharp challenge of the individual prerogative. The right of eminent domain is constantly evoked to further the legitimate interests of society. To permit a company to pollute a stream, doing continuous damage to a certain group of individuals because a greater number would be benefited by the operations of the company, is tantamount to expropriation. Judge Hunt affirmed (*Bliss v. Anaconda Copper Mining Company*, Fed. Rep. Vol. 167, p. 342) that the injury to a large popu-

lation would suffer to such an extent by granting an injunction against the *Anaconda* smelter as to compel adjustment by resort to the customary legal remedy for damages. He sought, however, to so frame his decree as to avoid the destruction of the rights of either litigant. Nevertheless he has re-affirmed the principle that the magnitude of capital should weigh in the decision. Manifestly mere disparity is an uncertain basis, and would not be recognized except for the number of individuals dependent for a livelihood upon the respective industries.

In California the question was fought long and bitterly between the hydraulic miners and the farmers. The contest was finally settled by the intervention of the Federal Government under its constitutional authority over navigable waters. It was a death-blow to a great industry, because the provisions for regulating hydraulic mining could not be made effective without more knowledge and experience of restraining dams and of the transporting of sediments by running water than then existed. Indeed, after four years of experimental work under Mr. G. K. Gilbert of the United States Geological Survey the California Débris Commission, for which the investigation is being made, is not ready to announce conclusions, so difficult are hydraulic problems. The law in the case, however, was stated in unambiguous terms: One may not deprive another of the enjoyment of his rights; the mere effort of one who infringes the rights of another to abate the nuisance does not exonerate him from responsibility; and finally, the doctrines of prescriptive right to commit a nuisance and of 'necessity', that is, inability to conduct a business without committing acts objectionable to others, have no application.

As opposed to this is the opinion of the Supreme Court of the United States in a case which is often cited (*New York City v. Pine*, 185 U. S. 93), dissolving an injunction which had been obtained against the City of New York. A dam was being constructed to impound the waters of Byram river, a stream flowing from New York into Connecticut, with the intent to use the waters in the metropolis. The contest was based on the common law principle of riparian rights. Mr. Justice Brewer delivered the decision, holding that "if the plaintiffs had intended to insist upon their strict legal rights they should have commenced at once before the city had gone to such great expense." A distinction was drawn between stating a right with proffer of a waiver for compensation, and stating a right with a demand that it be respected. Thus the question of diligence is introduced, which is a prime requisite of equity. "He who seeks equity must do equity." The man who allows without protest investment to be made by another that will result in certain consequences which can be foreseen, may lose the right to equitable relief. He may have a remedy for damages which can be appraised, but it seems manifestly unfair that under such circumstances the right of one person should be extinguished for the benefit of another. In the application of the principle of due diligence lies a safeguard of both public and private advantage.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

H. C. HOOVER is in Korea.

CHARLES BUTTERS is at Goldfield.

W. L. LELAND is in San Francisco.

CURTIS H. LINDLEY is at Salt Lake City.

J. POWER HUTCHINS is in San Francisco.

W. DeL. BENEDICT has returned to New York.

ELWYN W. STEBBINS has gone to Oaxaca, Mexico.

D. W. BRUNTON sails from New York for Europe today.

H. G. DENNY will make his headquarters hereafter at Oaxaca, Mexico.

MORRIS P. KIRK, of Salt Lake, is making some mine examinations in Arizona.

A. F. McEWEN is manager for the Jacobs Exploration Co., Ltd., at Cobalt, Ontario.

GROCH & GROCH have opened an office as consulting engineers, at Cobalt, Ontario.

G. K. GILBERT has gone to Jackson, Michigan, where he will henceforth make his home.

DOUGLAS WATERMAN has gone to Oroville, and thence will go to Plumas county, California.

FREDERICK H. MORLEY, of Denver, is examining mining properties near Prescott, Arizona.

JOHN COOPER is superintendent of the El Oro Mining & Railway Co., Ltd., at El Oro, Mexico.

F. CLEMES SMITH is general manager for the Superior Copper Co., Algoma district, Ontario.

J. F. McCLELLAND, of Stanford University, is giving a course of lectures in mining at Yale.

LOCHIEL M. KING has moved his metallurgical laboratories to 518 California street, San Francisco.

T. A. RICKARD delivered two lectures on the valuation of mines, at Stanford University last week.

E. McCORMICK is examining mining property in the Clifton-Morenci and Globe districts of Arizona.

ARTHUR S. DWIGHT has been appointed manager of the Humboldt smelter, Yavapai county, Arizona.

W. B. MILLIKEN is president and general manager of the Indiana-Nevada Mining Co., Pioneer, Nevada.

H. C. BELLINGER has been made metallurgical director of the Cobar copper mines in New South Wales.

H. S. ABBOTT has been making an inspection tour of the A. M. Gilbert Co. holdings in California and Nevada.

GEORGE D. REID is examining mines in the Snake River district, Oregon, and the Seven Devils district, Idaho.

F. C. KNIGHT, formerly metallurgist at the Garfield plant of the A. S. & R. Co., is in charge of a copper smelter in Siberia.

A. V. THORNS has resigned as manager of the Manley properties at Hot Springs, Ark., and will open an assay-office at Fairbanks, Alaska.

J. E. CLARK, formerly mine surveyor and assayer for the Monica Mines Co., is with the Golden Star Mines & Milling Co., at Kofa, Arizona.

DIÓDORO SANCHEZ, official representative of the Sociedad Columbiana de Ingenieros, touring the world in the interest of the industrial development of Colombia, was in San Francisco.

ROBERT HAWKHURST, JR., remains in Chile as general manager for the Poderosa Mining Co., of London, which has acquired the properties of the Compañia Minera de Collahuasi, Chile.

The PACIFIC COAST SECTION of the M. & M. Society will meet Tuesday evening, April 27, following dinner at the St. Francis hotel. M. L. REQUA will report on his conference with the Eastern officials of the Society.

L. VOGELSTEIN & Co., New York, give the following figures of German consumption of foreign copper for the months of January and February, 1909:

	Tons.
Imports of copper23,207
Exports of copper1,087
Consumption of copper22,120

As compared with consumption during the same period in 1908 of 28,404 tons. Of this quantity 21,660 tons were imported from the United States.

General Mining News.

ARIZONA.

GILA COUNTY.

Development at the Inspiration mine, near Globe, is well under way. The work consists of the driving of two cross-cut adits and one drift, all in low-grade sulphide, and the sinking of two shafts, which are now 50 and 60 ft. deep, respectively; the 50-ft. shaft is in oxidized ore. Gasoline hoists are being installed at these shafts. The Banker adit, which is in 2% sulphide, will open the mine 200 ft. deeper than the present workings. Two Star churn-drills have been received and will be used in prospecting the Inspiration ground. A. F. Holden is one of the directors of this company, George E. Gunn is manager, and Henry Krumb, consulting engineer.—The National Mining Exploration Co. is grading for a 3-compartment shaft for the development of its Iron Cap property. This shaft is situated on the Free America claim, about 3000 ft. northeast of the Iron Cap shaft and 1200 ft. west of the Eureka shaft of the Arizona Commercial.—The Superior & Boston has resumed sinking the winze in the bottom of the Great Eastern mine, and samples have been taken averaging 12 $\frac{3}{4}$ % copper, which give the consulting engineer, Frank H. Probert, the impression that the zone of secondary enrichment is being entered.

MOHAVE COUNTY.

The Arizona Excelsior Dredging Co. is being formed, to put a dredge on 640 acres of ground at Las Vegas Wash. The officers of the company are A. B. Call president, J. R. McDonald general manager, and H. J. Meyer secretary.—The Colorado River Dredging Co. is making good progress with its Dubois dredge in El Dorado canyon.

PINAL COUNTY.

Since March 15 the management of the Ray Consolidated Co. has added 4,300,000 tons to the probable ore reserves, as indicated by the churn-drills. This has been carried out under the supervision of H. Krumb. George O. Bradley is to take charge of construction of the concentrating plant, which is to be designed from the data obtained in the 200-ton experimental mill, now in successful operation.

About 800 tons of ore per day are being received at the plant of the Southern Arizona Smelting Co. from the Imperial mines, 14 miles south of Sasco. The two furnaces have been operated continuously during the past six months, and one of them has been working constantly for more than a year. The management is considering the installation of a third furnace, and this will probably be started during the present year.

CALIFORNIA.

AMADOR COUNTY.

(Special Correspondence).—The new station at the 1950-ft. level of the Bunker Hill mine has been completed, and extensive developments will be shortly instituted from this point. Large reserves of ore are in sight and the mill is running steadily. The company declared its regular monthly dividend on April 15.—A large vein of milling ore is being worked on the 3150-ft. level of the Kennedy. Work is about to start at the shaft, which will be sunk to a depth of 3350 ft. A large force of men is at work in the mine and mill. The installation of an air compressor and other machinery has been completed at the Original Amador, and work is about to be pushed on a comprehensive scale.—At the Argonaut over 100 men are working, and a considerable quantity of good grade ore is being milled. Developments in the lower levels continues satisfactory. R. S. Rainsford is superintendent. One giant is breaking down the big bank of gravel at the Garibaldi and several small nuggets and much fine gold have been extracted. Restraining dams prevent the escape of debris to the river. A deed of redemption, releasing the liens held against the California Con. G. M. Co., owners of the Wildman Mahoney and other mines at Sutter Creek, has been filed by a local attorney. The amount involved is said to approximate \$23,000. The

filing of this deed is considered an indication that the company is contemplating a resumption of early activity.—The Tennessee mine at Pine Grove has been re-opened and orders have been placed for a roller mill. W. A. Salisbury of Oakland is superintendent.—The shaft at the Central Eureka is down 2200 ft., and is expected to reach the level of the old workings within a few weeks.—At the South Eureka several men are working, and a daily shipment of ore is being made over the aerial tram to the Central Eureka mill. Twenty stamps are dropping.

Jackson, April 17.

ELDORADO COUNTY.

Two hundred acres of ground have been taken up in the old Spanish Dry Diggings near Greenwood, which have only been worked in a desultory way since hydraulic operations in the eighties. There is an abundant tonnage worth about \$3 per ton, and about 375 ft. of adit and other development work have been done. It is intended to treat the product in an 80-ton plant designed by the Joshua Hendy Co. A

Copper Region of Shasta County.

supply of 300 miner's inches is available, but only one half of this will be required. J. F. Pixley is the vice president of the new company, and the secretary, J. W. Hyatt, is now at the mine.

INYO COUNTY.

The Four Metals Co., operating a single smelting furnace at Keeler, has been producing \$2500 of bullion per day. The slag pile of the old Cerro Gordo smelter is going to be put through this furnace, in addition to the ore from the old Union mine. An aerial tramway has been erected between the mine and smelter, and is being given a test run.

NEVADA COUNTY.

An ore-shoot discovered in the Prescott Hill mine maintains a good value with development. It occurs between the 500 and 600-ft. levels, is about 3 ft. wide, and averages \$30 per ton. The same shoot is now being opened on the 700-ft. level, and a raise will be cut to follow it on the dip. On the 1200-ft. level drifts are being extended north and south. At the 1300-ft. station is an electric plunger pump, built in Grass Valley, which keeps the mine dry, working only eight hours per day. J. Brockington is superintendent.

The Posey Canyon gravel mine, three miles west of Grass

Valley, has made an unusually good weekly clean-up. The Posey company owns about 100 acres along the channel. An adit was driven 400 ft., when raises were put through into the gravel deposit. A drift is now to be run down the channel into the old Picayune workings. H. C. Zapf is president of the company.—The strike in the Sixteen-to-One mine, mentioned last week, turns out to be more excellent than described, for over \$20,000 was taken out in two days. The pocket was first cut in the adit 225 ft. from the entrance and at a depth of 100 ft. from the surface. In driving 25 ft. E. H. Wilson and the other owners have not yet reached the farther limit.

SHASTA COUNTY.

(Special Correspondence).—The Mammoth Copper Mining Co. ships about 1200 tons per day from the Mammoth mine to the smelter at Kennett. This ore goes from the mine, over the electric tram, then down the gravity tram to bins, whence it is pulled by a steam locomotive to the smelter. The aerial tramway has been closed for the summer, and will only be used in case of emergency. The lack of storage bins between mine and smelter make it necessary for the operations at the two ends of the line to be closely in balance. All ore is drawn from chutes in the 300 tunnel, which is 2310 ft. above the furnaces at the smelter. Robert E. Hanley is superintendent of the mine.—A small force of men is at work on the Summit mine, owned by the Stauffer Chemical Co. of San Francisco. This company bonded the property from the Phoenix Securities Co. of New

erty without developing any more ore. The result is that the property is in bad shape to sell.

Redding, April 16.

The sulphide ore-bins and sampling plant at the Balaklala Consolidated Copper Co. collapsed on Monday, owing to a very heavy tonnage in the former. A portion of the tramway was also destroyed, as it terminates on the top of the bins; it is of the Riblet system, 16,130 ft. long, and its part-destruction will temporarily interfere with the production from the mine.

SIERRA COUNTY.

The new tramway at the Gray Eagle mine, erected by Walter M. Painter, is working admirably, and the 10-stamp mill is kept busy on good ore.—Lawrence Holley has driven an adit in the Chipps mine, and has been fortunate enough to find a vein within 30 ft. of the entry.—Oscar Anderson is now in Sierra City, and will make an examination of the Butte Saddle mine with a view to purchase.

TUOLUMNE COUNTY.

Machinery has been purchased for developing the Green-Jumper mine, situated near Confidence. During the early days many thousands of dollars were taken out at shallow depth, and present prospects are pronounced good.—The winze started a few weeks ago in the 400-ft. level of the Driesam mine, at Arastraville is 70 ft. deep. A large crew of men is employed at the property, and the mill is running day and night.—W. D. Deming will in a few days resume development work at the Big Four mine, formerly known as the Smith claim. The property, situated one half mile east of Tuolumne, has an adit about 300 ft. long which exposes several promising shoots of ore. The rock carries free gold and sulphides, and assays from a few dollars to over \$500 per ton.—Several buildings are being erected at the Taramula mine, including a residence for the mine foreman, change-room, and office. An air-compressor will be installed.—The adit at the McCormick & McPherson mines, near Jacksonville, is 600 ft. long, and work in it continues. The Huntington mill is running steadily, but an inadequate supply of water will cause its idleness during the dry season.

COLORADO.

OURAY COUNTY.

W. J. Cox, the manager of Camp Bird, reports that a raise from the new drift in the west end of the mine has struck ore of an average width of 3 ft. and assaying over \$200 per ton. Sufficient work has not yet been done to find if it be an orebody of any magnitude.

IDAHO.

ELMORE COUNTY.

(Special Correspondence).—The Atlanta mining district, situated in the northeastern part of this county, was an important producer of silver in the early mining days. The rich orebodies occurred within a few hundred feet of the surface, and within the course of a few years were exhausted. Large bodies of low-grade gold and silver ore were known to exist, but could not then be treated at a profit. The camp is further handicapped by not having a railroad point nearer than Mountain Home, on the Oregon Short Line, 85 miles distant. Within the last year a wagon road has been completed from Boise to Atlanta. The road follows the Middle Boise river, has a good grade, and can be kept open during the entire year, as the winter just past has demonstrated.—The Pettit mine is owned by the Bagdad-Chase Mining Co., and employs 75 men. Wayne Darlington of Boise has been general manager. Practically all development has been confined to the Atlanta lode, of which the company owns 650 ft., together with several side claims. The mine is developed through cross-cut adits, and enough ore has been blocked out to keep the mill in operation for a number of years. The ore is conveyed to the mill by a gravity tramway 3500 ft. long. The mill contains 40 stamps and 2 tube-mills. About 40% of the value is extracted by amalgamation. Frue and Johnson vanners collect the concentrate, which is roasted in a reverberatory furnace previous to leaching with cyanide. The Atlanta Mines Co. owns the old Buffalo, Monarch, and Last Chance mines.

Map of Northern California.

York, and about 18 months ago, during the period of financial depression, it bought the mine at a low price. This mine is 3 miles beyond the Mammoth and lies just to the west of Section 29. There are three main adits: No. 1, 150 ft. long, running north; No. 2, below No. 1, and running north 450 ft., with a drift west for 300 ft. and a winze down 175 ft. on an incline; No. 3, on the opposite side of the gulch, is 450 ft. long, but has been abandoned. Work at present is confined to driving a cross-cut north from the bottom of the winze in No. 2 tunnel. This is in 160 ft. There are some prominent shear-zones in the porphyry, the main one striking a little south of west, in which some good chalcopyrite ore is found. In the ground north of the shear-zone some ore has also been struck. No shipments have been made, and transportation from the mine is difficult. An electrically operated compressor furnishes air for one drill, a hoist, and a pump. Charles Kunze is superintendent.—No work has been done at the Golinsky mine since the Guggenheims gave up their bond, and the surface mule-tram that was built as an extension of the Holt & Gregg narrow-gauge electric road, is falling into disrepair. The Guggenheims confined their operations to stoping out all the ore exposed, and when this was done they abandoned the prop-

Practically all of the development work has been done in the Monarch. The shaft is down 600 ft., and the vein is opened several hundred feet on either side, exposing an immense tonnage of ore, in many places 30 ft. wide. A two-mile automatic tramway conveys the ore to the mill, which was designed by W. T. Sherman of Park City. Several months ago a trial run of two months was made in this mill, and the concentrating machinery found unsuited to the ore, so the mill was closed down. Daniel Kirby, the manager, has been to Pittsburg to consult with the owner, T. N. Barnsdale, and new concentrators will probably soon be ordered. Both the Bagdad and the Atlanta companies own electric power-plants on the Middle Boise river.

Atlanta, April 16.

IDAHO COUNTY.

The quarrel between Frank Peck and A. Adams, the owners of the South Fork mine, eight miles from Elk City, has been amicably settled without recourse to the courts. Work at both mine and mill will shortly be resumed.

SHOSHONE COUNTY.

(Special Correspondence).—A shipment of concentrate from the plant of the Mitchell Concentrating Co. will be made this week. The machinery is said to be working well and to be giving excellent returns. The plant is working the tailings in the Coeur d'Alene river, and is leased for two years to Thomas Cameron of this city.—The Pennsylvania & Coeur d'Alene Mining Co. has commenced suit against its president, certain of its officers, the State Bank of Murray, and others. It is claimed that during the years 1907 and 1908 the sum of \$1300 each year was paid to the officers involved for the purpose of having the annual assessment work done, and that this money was appropriated by these men for their own use; and they then employed other of the defendants to re-locate the claims of the company.—A scarcity of water for power purposes has forced a temporary close-down of the Reindeer mine at Mullan. The adit has been driven over 2500 ft., and it is expected that the vein will be cut within the next 300 ft.—The 531-ft. raise on the Tamarack & Chesapeake property has been completed. What the next step in development will be has not been made public, but it is believed that a large concentrator may be erected. The showing of ore in the property is said to be second to none in the district.—At the delinquent sale of stock of the Hypotheek Mining & Milling Co. held in Wallace at the beginning of the week it was announced that all assessments had been met, and not a single share changed hands. This is almost a record in the Coeur d'Alene.

Wallace, April 17.

Leo Greenough, manager of the Snowstorm mine, says the company will pass the second dividend, due this month. No reason is given, except that the company is blocking out new orebodies, leaving the old unworked, until conditions in the copper market improve.—It is reported from Mullan that a strong flow of water has burst from the face of the west drift on the 400-ft. level of the National property, necessitating a shut-down. No more ground will be opened on the west side, the management fearing it will flood the mine. The pumps are taxed to capacity. A copper-galena vein 20 ft. wide was cross-cut a short time ago.

WASHINGTON COUNTY.

The directors of the Fidelity Copper Co. of Portland report the completion of a 400-ft. adit showing ore carrying 8% copper, \$4 gold, \$3 silver per ton for the entire length. They have placed orders for drilling machinery, and are preparing for heavy shipments when the railroad is completed from Huntington, which is promised in the early summer.

MICHIGAN.

At the Adventure all details have been worked out in connection with the proposed new shaft which will tap the three lodes disclosed by diamond-drill explorations last year. The work is expected to be in progress soon after the snow is melted. Operations will be under the direct supervision of the local management of the Quincy Mining Co.—The

Michigan Copper Mining Co. is opening rich ground in the so-called Bee workings, east of the Michigan mine proper. The lode has been opened for a distance of 100 ft. on the adit level, and shows uniform good grade of stamp 'rock'. The new discovery is 60 ft. west of and parallel to the Calico lode, from which a cross-cut is being driven to join them on the 800-ft. level.—The new vein on the 17th level of the Mass Consolidated mine shows 7 ft. of good copper-bearing amygdaloid, and several feet with abundance of the associated mineral epidote. The superintendent, James W. Wilcox, has opened the lode 41 ft., and a diamond-drill has cut the same lode 100 ft. lower down.—The New Baltic Co. expects to have two diamond-drills in operation shortly. Trenching has temporarily ceased, owing to spring freshets and the attendant difficulties in keeping the surface workings free of water.

The annual report of the Franklin Mining Co. shows that there was a deficit of \$28,000 at the end of the year. Practically all the work at the mine has been done at reduced

Mass Copper in Michigan.

costs. The total openings in 1908 aggregated 4305 ft.; the amount of copper per ton of 'rock' stamped was 10.82 lb., and the total cost per ton stamped was \$1.57. It is the intention of the Franklin management to assume control of the Rhode Island Co. in June, after which time the north drifts from the Franklin No. 1 shaft may be continued into Rhode Island property and open up what is believed to be valuable ground at very little expense. R. M. Edwards is superintendent.

MISSOURI.

JASPER COUNTY.

One of the best recent galena strikes was made on the old Log Cabin lease at Duenweg, where at a depth of 80 ft. rich ore was found. This tract has been a good producer for a number of years, and the new strike is not inferior to the former deposits. Its extent has not yet been determined.—The Pinnacle mill, which was recently completed in the Oronogo camp, is now producing. One shaft shows a face of ore 10 to 14 ft. high, carrying both galena and blende. Another shaft is being sunk for better ventilation. The company is now producing from 6 to 8 tons of zinc-blende per day, and about two tons of galena.—The Weaver Tri-City mill on the lease northwest of Carthage is now complete and ready for work. It is designed to treat 150 tons per day. This land was thoroughly prospected a year ago, and the ore developed to 200 ft. The shaft was later sunk, but various obstacles have caused delay in starting.—The Swayback mill No. 1 has been purchased by the Nowata Lead & Zinc Co., which will remove it to the new lease in Porto Rico. The lease comprises the Ruby tract, where fully 500 ft. of driving has been done. The ore there has hitherto been cleaned on hand jigs.—A new mill, the Regina No. 2, is being built in the North Webb City sheet-ground camp on the Guinn land. Some of the machinery is installed, and the plant will soon be ready for operation.

Two other mills are to be erected in this camp, one already being started, in which a new type of machinery will be used, which will decrease the cost of construction.

MONTANA.

MISSOULA COUNTY.

The Copper Hill Mining Co. is developing 12 claims on Sunrise gulch near Quartz. The vein running through the group, as shown on the croppings, is from 25 to 50 ft. wide and runs about 4% copper. The company has driven 75 ft. of an adit to cut the vein at a depth of 200 feet.

NEVADA.

ESMERALDA COUNTY.

The recent reduction by the railways in ore-hauling rates has proved a boon to the miners of this district, enabling them to have smelted at a profit ore which under the old rates could not have been shipped with sufficient profit. It is believed that while the railroads are not making so great a margin of profit on shipments as before, the volume has so increased that the aggregate net profit has shown a gain. Hopes are now expressed that further reductions may be brought about by the various officials of the railroads now in Goldfield.—An important strike of galena has been made on the Christensen lease of the Lucky Boy mine, at Hawthorne. The mine in general is doing very well and is shipping a carload of lead ore every day.—Systematic development is being carried forward in the Little Florence lease on the Combination Fraction, which has resulted in opening a large amount of low-grade ore, but no extensive body of shipping ore. The manager, George Vickers, says that the reports that a large amount of high-grade material had been found were without foundation. The new electric hoist and air-compressor that were installed a few weeks ago have greatly aided development.—Preparations are being made to install a 75-hp. hoist on the Grizzly Bear, which will be sufficient to sink the shaft to 1000 ft. The shaft is now down about 400 ft., having two compartments. No vein has yet been cut. The work is in charge of Bruce K. Jones.

LINCOLN COUNTY.

The Prince Consolidated Co., at Pioche, is working nearly 50 men; the Golden Prince, Gold & Silver Prince, and Pioche King making up another fifty. Dean S. Low, one of the principal owners of the Golden Prince and the Gold & Silver Prince, is erecting a fine residence near the mines. A 25-hp. Alamo gasoline hoist is to be installed at the latter mine, and other improvements include an electric light and refrigerating plant, a new boarding house, and an assay-office. Thomas Varden is mine superintendent.—E. F. Freudenthal is developing the Colfax property, in the Highland district of Pioche, with success. He finds that the shaft continues in silver ore as it progresses.—The Boston and Pioche mines have a good new orebody on the 600-ft. level, that is not less than 12 ft. thick.

NYE COUNTY.

(Special Correspondence).—Owing to the number of rich strikes recently made on its estate, the Queen Bethania Mines Co. has decided to dispense with future leases and will work the ground on company account.—At the Murray lease on Consolidated ground good ore is being broken and treated at the Murray mill. The shaft is going down in good ore.—New York engineers have been in camp during the last few days on behalf of Eastern financial interests. It is reported that they are desirous of securing control of the Rawhide Coalition and Queen properties. If the deal is made it is planned to sink three shafts on the Coalition, erect a 500-ton mill at Walker lake, and complete the Rawhide Western railway.—The construction of the Evans mill on Gold Dick hill is progressing rapidly. The first two batteries of stamps will be soon placed.—Milling conditions in this district are constantly improving and the cost is being gradually reduced. Many stamps are now crushing five tons of ore per day, and it is expected to do better in the near future.—Placer mining at Manhattan continues

to excite the district. Dozens of shafts are being sunk in the gulch and a number of claims have been located. The pay gravel is said to run from 14 to 70 ft. deep. Water is plentiful on several claims. Several small nuggets, in addition to free gold, have been found.

Rawhide, April 17.

The total output of the Tonopah mines last week was 5400 tons, of which the Tonopah Mining Co. produced 3100. Both mine and mill of this company have operated steadily without any unusual occurrences.—At the Belmont, development at the bottom of the mine, on the 1100-ft. level, continues excellent, and in the 1054-ft. winze another vein of high-grade ore has been cut, worth over \$200 per ton.—A break-down in the return-water pump at the Montana Tonopah mill prevented more than an average of 25 out of the 40 stamps dropping for four days.—Good progress is being made in the construction of the new power line of the Nevada California Power Co. which is being built between Millers, Manhattan, and Round Mountain. If no unnecessary delay occurs, the wires should be strung to Manhattan early in May.—Eighty-four tons of ore were sent out from the Pioneer, near Rhyolite, one day, and 100 tons another day. In a month it is hoped to improve this to 200 tons per day. A compressor and 5 drills have been started and 3 more drills have been ordered. The best ore is coming from the bottom level.—The Beatty custom mill will be ready for operation some time next month, as nearly everything is installed except the power. It contains 10 stamps and supplementary equipment, and arrangements have been made for maintaining a continuous supply of ore.

WHITE PINE COUNTY.

The Steptoe Smelting & Mining Co., which concentrates and smelts the ores of the Nevada Consolidated and Cumberland-Ely mines, is receiving approximately 4000 tons per day at the Steptoe mills, three units of which are in operation. Unit No. 1 treats 1500 tons per day of Cumberland-Ely ore, which is largely a sulphide running 3% copper; units No. 2 and 3 operate on Nevada Consolidated ore, also a sulphide, running about 2.3% copper, the daily tonnage being about 2400 tons. Cumberland-Ely ore is concentrated in the ratio of four into one, the Nevada Consolidated ore about nine to one. Unit No. 4, to have the same capacity as the others, is being constructed and machinery being installed. It is expected to be ready for operation next July, and will be run on Nevada Consolidated ore.—At the Steptoe smelter three reverberatory furnaces, each 111 ft. 10 in. long, with 6 by 10-ft. fire-boxes, are in operation, each furnace handling about 300 tons per day of concentrate after same has undergone roasting in the MacDougall roasters. The furnace product, a 45% copper matte, is passed to the converters, of which there are three stands. The plant has been producing 3,750,000 lb. of copper per month, but this production is increasing. The blast-furnace equipment is partly in place, but not completely installed. The fourth reverberatory furnace is being built, and it is stated that it will be ready as soon as unit No. 4 of the mill shall be finished. It is observed that the slag tapped off from the reverberatories is granulated and carried away in the mill-tailing. S. S. Sorensen is chief engineer and superintendent of the smelter, G. F. Waddell is mill superintendent, J. D. Watson being mechanical engineer for mill construction. C. B. Lakenan is general manager for all mining, milling, and smelting operations.

NEW MEXICO.

SOCORRO COUNTY.

The Chemung property, in the Burro Mountain district, is developed to the 500-ft. level, and an orebody has recently been followed for 45 ft. on that level, averaging 3½% copper.—Officers of the Pan American Federal Smelting & Refining Co., which has undertaken the work of rehabilitating the old Billings smelter at Socorro, report that a bond issue of \$100,000 has been disposed of. Included in the trade for the smelter is a tract of land amounting to 183 acres, and a pipe-line 1½ mile long which will supply water to the plant.

UTAH.

BEAVER COUNTY.

The Kincora Mining & Milling Co., which was recently incorporated, is the owner of a group of eight claims in the Beaver Lake mining district. This property adjoins the Newhouse Copper Mountain property. The development work thus far has consisted of an adit about 200 ft. long, and is to be advanced. The mine is 6 miles from the railroad, and 13 miles from the town of Milford.

SALT LAKE COUNTY.

With the commissioning of the tenth section of the Boston Consolidated milling plant, near Garfield, and the increase of shipments from the porphyry deposits, this mine will take rank as the second largest copper producer in Utah for the remainder of this month. These 10 sections can be counted on to treat 2250 tons per day, and there are three more to bring into operation before long.—Samuel H. Treloar has sunk the shaft of the Bingham Butte mine into a body of rich copper ore at a depth of 180 ft. below the main adit level. He declines to give the assays till he has sunk enough to be able to state its average value.

SUMMIT COUNTY.

The mill of the Silver King Coalition is treating 450 tons per day. Crushers, rolls, and Huntington mills do the crushing and grinding; the concentrating is on Hartz jigs, Wilfley tables, Frue vanners, and Wilfley slimers. Revolving screens do the classifying ahead of the jigs, and Callow traveling screens ahead of the tables. The undersize from the 30-mesh Callow screens is settled and de-watered in a V-shaped gravity settler. The vanners operate on a finer mesh material than do the tables; and the slimers handle the overflow from the spitzkasten and the underflow from the settling-cones. They are not now using the filter presses for collecting the flocculent slime as formerly. J. W. Thompson, mill superintendent, has put into use a sampling device of his own, which works admirably.

WASHINGTON.

FERRY COUNTY.

The smelter returns from five carloads of ore shipped from the Republic mine by the New Republic Co. show the average value to be \$70.50 per ton, the contents being in the ratio of 4½ oz. silver to 1 oz. gold.—The Spokane Falls & Northern Railway Co. is clearing the roadbed of debris on the spur to the No. 3 adit, to facilitate shipments. The mine has been cleaned up, from the surface down to the 600-ft. level, and is now in excellent shape for mining.—At the San Poil mine four men are working under lease and shipping two carloads of ore per week, averaging about \$20 per ton. An order has been placed for a Fairbanks-Morse 3-drill air-compressor, to be electrically driven by power to be supplied by the New Republic Co. The ore produced comes from the upper levels.

OKANOGAN COUNTY.

A small force is now employed in the Palmer Mountain Tunnel & Power Co.'s main adit, now in about 4500 ft. The manager at the mine says that probably only development work will be done this season. The mine is situated near Loomis, 12 miles south of the International boundary line. Twenty-eight veins, of varying width, are said to have been intersected in the course of this adit, and about 3600 ft. of laterals and raises have been made on the various veins. About 1200 ft. west of the mouth of the main adit is a 100-stamp mill, built by the Traylor Engineering Co., equipped with 20 Garvin cyanide machines.—A shaft on the Olen-tangy mine has been sunk to a depth of 142 ft. and has found ore, none of which assays less than \$18. Cross-cutting will be started when the 150-ft. point is reached. There is a 30-hp. gasoline hoist and an Ingersoll-Rand compressor at the mine. John H. Arnold, president of the company, is now at the mine.

CANADA.

BRITISH COLUMBIA.

The Greenwood Phoenix Tramway Co., of Chicago, has started preliminary work on the 3 mile tunnel to join the

towns of Greenwood and Phoenix. Local taxpayers have voted \$50,000 to the company, and the remainder of the necessary money has been subscribed in New York and Chicago. Compressors and electric drills are being installed at the Greenwood end of the tunnel, and it is given out that construction work will begin in a short time. As the undertaking does not involve any unusual engineering difficulties, it is believed that rapid progress will be made from the start. The tunnel in the course of its advance will cut numerous veins, believed to be 18 in number, in the first 6000 ft. The first will belong to the Strathmore mine, after which follow the Defiance, Yellowstone, Idola, Don Pedro, and Crescent.—A. B. W. Hodges, general manager of the Granby smelter, is taking the opportunity of the low price of copper to remodel the furnaces, two at a time. The first pair have already been enlarged, and on a trial run treated 530 tons each.—Paul S. Cauldrey, manager of the Le Roi No. 2, is shortly to retire from the management of that mine.

YUKON TERRITORY.

Arnold F. George, the secretary of the Miners' & Merchants' Association of Dawson, has made a detailed report of the placers of the region for the Mining Commission of the Yukon. It thoroughly covers the operations conducted on Forty-Mile and Sixty-Mile creeks, besides those in the district known as the Upper Stewart.—The dredge intended some day for the Miller creek concession, owned by the N. A. T. & T. Co., will not be ordered till the fall. It has been found by trial that when the gravel is cleared of 'muck' and is allowed to remain three or four years untouched, the thawing process continues alone until the entire gravel deposit is softened. This method does away with the expense of thawing by steam-points. It is probable that the dredge to be ordered will have 3-cu. ft. buckets, or much smaller than those now in use on Bonanza and Hunker creeks. In places Miller creek is not more than 75 ft. wide, with rather steep hillsides adjoining. The 'muck' will be moved this summer by water under pressure, and it is expected to sluice off enough to open about 200,000 yards for thawing. Guy A. R. Lewington is the engineer in charge, and 15 men will be employed.—The Pueblo, owned by Byron White of Spokane, is not shipping any ore, on account of the low price of copper and the heavy transportation charges. This property is looked upon as being the most promising in the district, there being an immense body of ore which is said to run 31½% copper, in addition to gold and silver.—The Arctic Chief has also been closed down since last fall, on account of the prevailing conditions. The ore of this property is rated at 8% copper. It is claimed that this mine possesses about 250,000 tons of probable ore. Capt. John Irwin of Victoria, B. C., is the owner.

MEXICO.

Baja California.

The second largest producer of copper in Mexico is the Compagnie du Boleo, operating near Santa Rosalia. This property is controlled by the French house of Rothschild, and all the copper is shipped direct to France. Consequently little is heard as to this company's operations. In 1907 the copper production was 24,530,000 lb. When the Greene-Canaanea property shut down, this company secured 2000 of the Greene laborers, as a result of which its operations were materially increased, and its production for 1908 is believed to have been in excess of 30,000,000 lb. Until December 1912 the company enjoys special exemptions from Federal and local taxation, granted by the Mexican Government. Ernest Michot is manager.

Chihuahua.

Connections have now been made between the adit and main shaft of the Palmilla mine. The adit is 343 m. long, and will save a lift of 133 m. in pumping. Sinking is being continued in the main shaft.—Geo. V. B. Levings has been appointed manager of the El Rayo Mining & Development Co. He succeeds Bert Peterson, who died in California in February. Levings was formerly assistant manager of the property.

Special Correspondence.

TORONTO, CANADA.

Cobalt Lake Decision. — Shipments. — Crown Reserve Report. — Chambers-Ferland. — Nipissing. — Gowganda.

The Cobalt Lake case, which has figured so extensively both in the courts and the legislature, and had become an important political issue, is at length settled by the judgment of the Court of Appeal. The noteworthy feature of the case was the interference of the Ontario Government with the ordinary routine of the courts by the passing of a special act guaranteeing the title of the Cobalt Lake Mining Co. to the property in dispute, namely, the bed of Cobalt lake, and declaring the claim unimpeachable, although an action was at the time pending by the Florence Mining Co. on the ground of previous discovery. This measure aroused a good deal of controversy, quite apart from the merits of the case, and was condemned by many as a dangerous precedent and an unwarranted attack upon vested rights. It was claimed that the act was *ultra vires*, and an attempt was made to invalidate it, but both the Canadian Government and the courts pronounced that it was within the prerogative of the Legislature, and therefore could not be upset merely on the ground that it was bad legislation. The Court of Appeal, while upholding the act as giving an indefeasible title to the Cobalt Lake Co., went into the merits of the Florence Mining Co.'s claim, and decided that, even apart from the validating act, the case of the plaintiff, based on an alleged prior discovery by W. J. Green, had not been made out; that Cobalt Lake was closed to prospectors at the time the discovery was made, and that although a contrary inference might have been drawn by Green from the maps and literature supplied to him by the Government, a simple question put by him to any of the officials would have set him right. This ends the matter, so far as this particular dispute is concerned, but it does not by any means remove the bad impression left in the minds of investors by the action of the Government.

Shipments of ore from Cobalt continue heavy. March was a good month, the output amounting to 2561 tons, as compared with 2103 tons in February, and 2375 in January. The total shipments for the quarter, 7040 tons, were twice the amount of shipments for the corresponding months of 1908, which only totaled 3481 tons. Dividends paid by the principal mines have also been heavy. The Crown Reserve has issued a financial statement covering the first three months of the year, showing ore shipped having a total net value of \$452,405. Operating expenses amounted to \$45,779; the amount spent on plant was \$10,949, and royalty paid the Government was \$40,168. Dividends of \$256,322 were paid, leaving a surplus of \$90,185, making a total surplus at the end of March of \$437,302. It is officially stated that at a depth of 75 ft. in the west winze below the 100-ft. level the vein has strengthened and is yielding rich ore. A winze is being sunk at the east end of the vein that will block out ore on three sides. The Foster has continued development from additional funds secured from New York. The advance is to be protected by a percentage interest in the output. The Kerr Lake has declared the regular quarterly dividend of 4%, in addition to a bonus of 2% payable June 15. The Coniagas has declared the regular quarterly dividend of 3%, payable on May 1. At the Chambers-Ferland water has considerably retarded work in No. 1 shaft, making it necessary to install an extra pump. Driving at the 150-ft. level has been done north and south for about 80 ft., the vein averaging 3 in. and carrying about 5000 oz. silver per ton. The engine house of the Beaver was burned April 5, but the mine was only idle for a few hours, as arrangements were made with the Temiskaming for a supply of power. The north half of the Bailey property has for some time been under lease to the Cobalt Central. The lease was cancelled April 1 and the Bailey is arranging to install its own plant and will do diamond-drilling. The annual report of the Nipissing will shortly be distributed to about 12,000 share

holders, as against 14,600 one year ago, some of the larger interests having absorbed much of the stock. The ore reserves are estimated at \$2,500,000 gross. It is claimed this estimate is based on more conservative methods than have hitherto been followed. During March ore of an estimated value of \$141,623 was mined, and shipments made of the value of \$193,845. Recent important developments include the striking of ore on the 175-ft. level of vein 64; the cutting of veins 89 and 67 from the 60-ft. level at the Kendall; and the increased showing of ore in vein No. 26 below the 110-ft. level. E. W. Beidler, superintendent of the Alexander, is arranging for the installation of a diamond-drill in the bottom of the main shaft, which is now down 170 ft. A vein found at the depth of 160 ft., where it was a narrow stringer, has widened at the 170-ft. level, and shows good silver content. A new calcite vein 6 in. wide has been discovered on the surface. A small 3-drill compressor has been installed on the Silver Cross property and driving is being done on the veins upon which the two shafts were put down.

Owing to the breaking up of the winter roads, Gowganda is now practically inaccessible, except by walking, though at last accounts a few teams were carrying light freight at enormous rates. There is consequently a lull in Gowganda flotations. So many of these have been made, at a time when the investing public was disposed to be shy, that Gowganda bids fair to be a disappointment. Few of the companies will be able to secure adequate capital for development. Over-capitalization has been carried to an absurd extent, and this, taken in connection with transportation deficiencies and the consequent enormous expenses of installation of machinery and shipment of ore, casts a doubt on the realization of dividends. Gowganda is much more likely to repeat the history of Larder Lake than of Cobalt. Until the transportation is properly organized at least, investors should be cautious.

LONDON.

Globe & Phoenix, Rhodesia. — Victoria Falls Power Co. — Rand Power Contracts. — Vereeniging Station.

Perhaps the most successful gold mine in Rhodesia is the Globe & Phoenix, at Que Que, or rather, the Phoenix, for the Globe itself is now shut down. Though the workings are at considerable depths, the cost of operation are gradually being reduced, and the grade of ore developed is improving. Good extraction is made, in spite of the fact that antimony is present. During 1908 the mill treated 75,413 tons, yielding 36,740 oz., or 8.05 dwt. per ton, over the plates, and losing 3.95 dwt. in the tailing. Further treatment consists of cyaniding the sand and slime. The sand treated was 51,704 tons, and the yield was 4036 oz., or 1.78 dwt. per ton. This cyanide treatment gives a low extraction, but even then the product was half profit. The slime plant is not so successful in handling slime now made, extracting not much more than one third of the gold content. On the other hand, accumulated slime works better, the yield being 80%. The total value of the gold won during the year from all sources was £154,555, and the profit, after making full allowance for mine development and depreciation, was £39,511. The year commenced with a balance in hand of £48,000, and £40,000 has been distributed as dividend. This is at the rate of 20% on the capital of £200,000, leaving £47,000 to be carried forward. The company has therefore plenty of available funds; in fact, besides the balance it has a reserve fund of £33,600 invested in good securities. As regards ore-reserves, the figures of December 31 last stood at 144,348 tons of an estimated content of 16 dwt. This is a notable increase within the year, both in quantity and content. In the current year not quite so much development can be done, for the depth of the workings has rendered it imperative that attention should be devoted instead to the provision of additional hoisting plant. During the year a sorting and jiggling plant has been provided, for the better elimination of the antimony. As regards costs, they amount to £1 2s. 0d. per ton, as compared with £1 4s. 0d. a year before. In addition, 4s. is charged for mine development,

bringing up the total costs to £1 6s. 0d. per ton in 1908, and £1 8s. 0d. per ton in 1907. The total costs were £99,964, but London expenses, depreciation, and income tax add a further £17,400, or 4s. 6d. per ton.

The application of electric power to mining on the Rand is progressing rapidly. The Victoria Falls Power Co. was formed two years ago to utilize the water-power of the Victoria Falls on the Zambesi river. It was originally planned to generate electricity on the spot and bring it to Johannesburg. Subsequently it was found that there was difficulty in getting right-of-way for the lines, and the Transvaal Government did not care to grant the right of condemnation. It was found also that the cost of installation and transmission would probably be greater than that of a local steam-plant. There were also complications arising out of a rival scheme for generating current at Vereeniging, on the Orange River Colony border, where the local coal resources could be used. Eventually local steam-power stations were decided upon, and as a start the generating stations of the Rand Central Electric Works were purchased. The company, finding that the line to Victoria Falls would have to wait, altered its name to the Victoria Falls & Transvaal

proximately 15,000 hp., and within a few years the amount will be doubled. Another important contract is with the Consolidated Goldfields, which has contracted to take power for the Simmer & Jack, Simmer & Jack East, Simmer Deep, Knights Deep, Jupiter, and Robinson Deep. These will take 40 million units. The Barnato group will take 33 million units for the Consolidated Langlaagte and the Van Ryn Deep, and similar contracts are made with the Albu and Goerz groups, besides other mines, such as Jumpers, Brakpan, Witwatersrand Deep, and Knights Central. Within three years the total output will be about 400 million units. The company has also made an agreement to establish a generating station of 30,000 hp. at Vereeniging, provided the Government will allow the transmission poles to be erected across country. Other contracts provide for the acquisition of interests in local collieries. These facts show the extent of the company's operations. Without doubt the electric power supplied will further reduce the costs on the Rand and make it possible for low-grade ores to be worked which otherwise would have to remain untouched.

JOHANNESBURG, TRANSVAAL.

Modern Deep Level Mining. — Some Daring Proposals. — A Single Shaft.—Amalgamation Process Eliminated. — Stamps, Chilean, and Tube-Mills —Scheme of Administration.

One of the most daring papers read at a meeting of a Rand technical society for many years was delivered by H. H. Johnson, manager, and H. F. Roche, mine captain, of the Village Deep, Ltd., before the South African Assoc. of Eng. on March 6. The magnitude of the subject, namely, the surface equipment of deep-level mines, recalls H. S. Denny's paper on the 'Metallurgical Practice of the Witwatersrand' read in 1903. Just as that contribution to technical literature evoked a vigorous discussion and stimulated research in certain directions to the lasting benefit of the industry, so will Mr. Johnson's paper form a basis of keen and useful controversy. The suggestions are, admittedly, not all original, but the authors have introduced with their own a number of parentless ideas. The paper touches upon many salient problems of modern mine equipment. The authors start by assuming the case of a representative deep-level mine of the future "This will be upward of 1500 claims of 60,000 sq. ft., containing, we will assume, 50,000 milling tons per claim." This assumption of 50,000 milling tons per claim is probably too optimistic for a representative Rand deep-level mine, especially of the East Rand—the great deep-level district of the future. The great claim-area is assumed in order that working costs per ton may be brought to 'the irreducible minimum' by large scale milling, and to provide for a life of a length sufficient to make unnecessary for many years the setting aside of profits for the redemption of capital. The property assumed would contain 75,000,000 milling tons, and for this a plant would be erected to treat 150,000 tons per month, or 5000 tons per diem, to "obtain a life of not less than 45 years." Mr. Kotrjé, the Government Mining Engineer, commented that such a length of life could scarcely be considered the most profitable, and suggested that it would be better to deal with the ground in areas smaller than 1500 claims. On the other hand, the idea of an 'indefinite' life—say, half a century—has gained great popularity in financial circles, as witnessed in the case of the recent Crown Mines amalgamation. To supply 5000 milling tons per day, after allowing for 18% sorting, it would be necessary to hoist about 7000 tons per day, excluding Sundays. The authors propose one deep-level vertical shaft of nine compartments, 58 by 9 ft. outside timbers, giving four compartments for rock, four for men, stores, and material, and one for pipes, cables, and ladders. They assume that "connection will be made with the properties nearer the outcrop, even if payment has to be made." Although this provides for ventilation and safety, it is doubtful if such a scheme of extreme centralization—in a mine presumably about 1½ miles across—will be generally favored. The authors have promised a companion paper

Map of the African Goldfields.

Power Co. In addition to the Rand Central works, the company owns generating stations at Brakpan and Simmer Pan, and it supplies a number of mines with electric power. Recently a contract was secured to supply power to mines belonging to the Rand Mines and the Eckstein group, and it became necessary to issue new capital to provide funds for the extension of the generating plant. The present issued capital of the Victoria Falls company is 1,000,000 ordinary shares of £1 each, 800,000 preference shares of similar denomination, and £800,000 of debentures. The additional capital now being provided amounts to £900,000 in preference shares and £900,000 of debentures, and as the issue has been underwritten, the scheme will proceed without delay. The new contract with the Rand Mines group will be cared for by a specially formed subsidiary company, the whole of the capital of which will be subscribed by the Victoria Falls company out of the money raised from the present issue. The mines to be supplied by this contract include the following Deeps: Glen, Rose, Geldenhuis, Jumpers, Village, Ferreira, Robinson Central, Crown, Langlaagte, and City, together with Nourse Mines, Village Main Reef, Robinson Gold Mining Co., Bantjes Consolidated, and New Modderfontein. At first the amount of current taken will be 130 million Board of Trade Units per year, which is ap

discussing the underground conditions. Comment on this point may be deferred, therefore, until the systems of underground traction and plan of inclines are described. The vertical depth of the shaft would be about 4000 ft. Electric hoists would be used, with cylindro-conical drums arranged for hoisting at a maximum speed of 4000 ft. per minute, with 7-ton skips. Allowing for stoppages, inspections, and other delays, it is assumed that the two hoists will handle 7000 tons per day. The principal features of the arrangements proposed at the shaft-head are large ground-level storage bins (1000-ton capacity), divided into compartments for fine and coarse rock, and long grizzlies with mechanically operated moving bars instead of trommels. The ore would be conveyed to the crusher in 2-ton, side-tipping, cars, discharging the coarse into concrete chutes having sprays to clean the rock prior to sorting. Picking belts 36 in. wide are designed to run from the bottom of the chutes. From the belts the ore would go through coarse crushers to fine sorting belts, following which fine Blake crushers are proposed.

The part of the authors' paper which deals with ore-reduction and gold-recovery appears, in the light of Rand practice to date, to be the most hazardous and original. Put as briefly as possible, their proposals are as follows: The mill is to consist of 260 stamps of 1250-lb. weight and, as in the new Simmer Deep plant, timber will be used for only the king-posts, guide-blocks, and platforms. Mortar-box foundations will be of concrete, without anvil blocks. This latter provision is of interest, seeing that the Village Deep, with which the writers are associated, was one of the first to adopt anvil blocks. The implied condemnation is not supported by arguments. The mill-bins, of 12,500-ton capacity, would be constructed of reinforced concrete. The superstructure will carry the shuttle-belt upon which the crushed ore and fine will be delivered by conveyor belts. In the treatment of the ore, amalgamation would be eliminated altogether. This idea is not advanced with any claim to originality. It has, indeed, been in the minds of local engineers for some time. The move made by the Eckstein Central administration has already been noticed. Experiments on a working scale will shortly be undertaken. The scheme proposed by Johnson and Roche, however, is far in advance of anything yet publicly suggested, and involves radical changes which few directors would care to finance without gradual demonstration. Immediately in front of each mortar-box, they suggest cone-classifiers set on separate foundations, to extract the bulk of the minus-200 mesh sand, the underflow going to improved Chilean mills. "Each five stamps will then crush 100 tons per day through $\frac{3}{4}$ -in. mesh, giving a stamp-duty of 20 tons per 24 hours; 20% of this product will pass a 6-mesh screen in addition to the 20% which will pass a 30-mesh, making 40%" which will not require to be re-ground in the Chilean mills. Such a definite pronouncement as to resultant conditions when using stamps for this unnatural class of work does not appear to be warranted by the lessons of past experimenting on such novel lines. The subsequent deductions, however, follow if the premises be accepted. The coarse product from ten stamps would go direct to one Chilean mill of 120-ton capacity discharging through 300-mesh. The pulp therefrom would be elevated by tailing pumps to de-waterers and cone-classifiers, all the slime being here eliminated and the coarse sand delivered to a battery of 20 tube-mills (5 ft. 6 in. by 20 ft. long). Tube-mill pulp would be returned to the general flow from stamps for re-elevation to the classifiers. The clean sand from the classifiers would be discharged to drying tables of the Caldecott type (lately introduced at the Simmer & Jack and Simmer Deep mills), which in turn would deliver into a launder in which cyanide solution would carry the sand through pumps to the sand-treatment vats. The sand plant will comprise 25 treatment vats of 1000-ton capacity, fitted with Butters & Mein's distributors, and the slime-plant of 8 settling and 16 treatment vats, 80 ft. diam. This is 10 ft. larger than the greatest in use at present on the Rand.

Quoting the experience of the Homestake mine, the

authors propose the use of zinc-dust for precipitation. They include in their paper a scheme of administration, not entirely new, and which will probably be adopted even though milling and cyaniding methods remain practically unchanged. The general policy will be laid down initially by the consulting engineer in conjunction with the board of directors. The general manager will reside at the mine and be responsible for the direction of work, being aided by an assistant manager. The engineer will be responsible for the whole of the underground and surface hauling, the sorting, crushing, and the milling as far as the Chilean mills or, in ordinary practice, as far as the stamps. A chief metallurgist will be in charge of all gold recovery operations, assisted by the necessary foremen in each branch of work. Many portions of the paper will meet with general approval, but the authors must be prepared for criticism of their system of dealing with so great an area through one vertical shaft and of using stamps to perform the functions of fine crushers or of rolls, for the feeding of Chilean mills.

The sixth ordinary general meeting of the Premier Diamond Mining Co. was held on February 23, and was noteworthy for the mass of useful information provided to shareholders and for the bold, uncompromising attitude adopted by the managing director in his criticism of De Beers. Ross Frames did not mince matters by elaborate explanations of the change in the relationship between the Premier company, De Beers, and the London Diamond syndicate, but plunged bravely into an attack upon the Kimberley corporation, accusing it plainly of having caused the fall in the diamond market by its over-production, and also of exaggerating the significance of the collapse in order to impress upon the Transvaal concern the advisability of curtailing its yield. The chairman, Mr. Cullinan, read the report of the company's London agent, announcing an improvement in the market and a satisfactory outlook. In spite of these assurances, it is impossible to regard with composure the Board's firmly expressed determination to continue the expansion of work at the mine. Last year, the Premier turned out 2,078,825 carats of diamonds. The mine appears to have arrived at a permanent grade of 25 to 26 carats per 100 loads. When the new treatment plant is in full swing, 50,000 loads (16 cu. ft.) per day will be treated, or roughly 16,000,000 loads per annum, for a yield of 4,000,000 carats. Owing to the increased scale of work and higher efficiency, working costs will stand at 1s. 6d. per load, so that the cost per carat will be about 6s. From the purely technical point of view, the records reflect the highest credit upon the company's management, but the craving for low costs obtained by working enormous quantities of ground cannot fail to lead to financial difficulties in the commercial departments. A monopoly in diamonds ceases to exist, and we must look to South Africa's proverbial good luck to relieve the disquieting situation established by two rival concerns of unlimited resources—one curtailing operations to suit the times, and the other boldly duplicating its capacity—which are supplying a sensitive and weakly convalescent market through competitive channels.

NEW YORK.

International Smelting.—Bonanza Copper.—Tennessee Company.—Inspiration Copper Co.—Rawhide Coalition.—Curb Rules.

Stock in the International Smelting & Refining Co. was over-subscribed, and the first allotment of \$10,000,000 has been made. The stock was issued at par of \$100 per share. The first quotations on the New York Curb are \$130 bid and \$140 asked. The board of directors includes John D. Ryan president, Dennis Sheedy vice-president, J. D. Allen treasurer and secretary, and Urban H. Broughton, Chas. F. Brooker, Thomas Cole, Adolph Lewisohn, E. C. Converse, Thomas Morrison, C. A. Congdon, Chas. F. King, J. W. Allen, and William D. Thornton are directors. The company will not confine its operations to copper mining, smelting, and refining, but will deal in metals, mines, and in mining and metal stocks. Options have been taken on controlling

interests in the Allis-Chalmers Co., the American Brass Co., the International Nickel Co., and other metal companies. It is believed that the company will later extend its operations to lead, zinc, and aluminum. It will also operate extensively in stocks in Wall Street.

It is announced that J. P. Morgan & Co. have completed arrangements for the purchase, from Norman Schults and the Havemeyer estate, of the Bonanza Copper Mines, Alaska. These were formerly known as the Kennicott mines, and are situated about 180 miles northeast of Valdez.

The directors of the Cerro de Pasco Copper Co., Peru, have instructed the manager to keep up production to the full capacity of the smelter. The output at present is about 4,000,000 lb. monthly. In response to the numerous protests of the shareholders, Walter Lewisohn, president of the Tennessee Copper Co., states that it is possible that a dividend will be declared shortly. At the recent meeting the directors considered it advisable to take no action in regard to a dividend, owing to the poor condition of the copper market and the uncertainty surrounding the company's negotiations for the sale of its output of sulphuric acid. As the fertilizer manufacturers concerned have already paid a deposit of \$500,000, it is most probable that the deal will go through. The Tennessee Copper Co. will then have a steady purchaser for all the acid its \$1,000,000 plant is able to produce. The Inspiration Copper Co. has been formed, with a capital of \$10,000,000, divided into 100,000 shares of preferred stock and 900,000 shares of common stock, to develop some copper claims adjoining the Miami Copper Co.'s claims at Globe, Arizona. The stock has been underwritten, and is quoted on the New York and Boston Curb and on the Kansas City and Salt Lake Mining Exchanges. The company's property comprises an area of 400 acres, and is reported to contain a large copper deposit assaying about 2% copper.

There has been a bad slump in the prices of the North Butte Copper and the Rawhide Coalition mining companies' shares on the New York Curb. Heavy selling of the Montana company's shares was started on the Boston Curb by rumors that the copper ore in the bottom level of the mine is so low as to be unworkable. The Rawhide selling was due to some peculiar tactics of the chief promoter, the ex-convict Herzig, who has lately been doing business under the name of George Graham Rice. For many months Herzig and his partner, Nat Goodwin, have carried on an extensive advertising campaign and stock has been widely placed.

The Curb Market Committee in New York having decided to weed out a number of the undesirable mining companies whose stocks are quoted on the Curb, E. S. Mendels, the committee's secretary, requested all companies whose shares are quoted on the Curb to furnish the committee with their latest reports, maps of mines, engineer's and manager's statements, financial statements, and all other data necessary in estimating their present standing and prospects. The committee proposed to keep itself informed of the operations of all mining companies whose shares are quoted on the New York Curb, and will suspend all companies who refuse to supply the information, which will be filed and open for public inspection. The following companies, having failed to file the necessary information, are hereafter only to be quoted as unregistered: The Banner Mining Co. of Goldfield, Bingham Argentite, Consolidated Red Top Lease Co., Cananea & Globe Exploration & Developing Co., Christmas Wonder, Ely Witch Copper Co., Elkhorn, Fairview Falcon, Galena King, Goldfield Ore Mining Co., Gold Belt, Golden Sceptre, Great Bend Extension, Goldfield Lucky Boys Mining Co., Hannapah Mining Co., Kewanas Mining Co., Link Chain Belt Co., Lone Pine, Manhattan Atlas, Mayflower Extension, Peerless Bullfrog Mining Co., Prairie Bell, Queen Alexandra, Right of Way, San Pedro Mining Co., Sandstorm, St. Ives Mining Co., Tramps Consolidated Extension, West End Consolidated Mining Co., and Watts Mining Co. The secretaries of several of the above-named companies have informed the committee that the desired information is being prepared and will be submitted shortly. It is therefore probable that some of the companies will be reinstated.

MANAGUA, NICARAGUA.

Banbana Concession.—Currency Depreciation.—Wage Scale.—Mining Taxes.—Leonese Mine.

Nicaragua seems to be attracting increasing attention. Henry F. Lefevre is due in Bluefields in a few days to examine a concession on the Banbana river, for Minor Keith, well known in connection with the United Fruit Co. and railroad building in Costa Rica. The concession consists of 2½ kilometres on either side of the river and all of its tributaries; it concedes all the undenounced mining land on the Banbana from its source to its junction with the Bana Cruz. The option-price is said to be \$250,000 gold, but as the ground is entirely unexplored, it is doubtful whether it will command cash. It would be like 'buying a pig in a poke'. The concession grants certain other rights, such as the free use of timber on Government land, the right to run steamers on the river, and the free introduction of supplies. The latter is a privilege already provided by law, and of no value unless it be stretched to include other merchandise. This would, of course, be bitterly contested by the merchants in Bluefields. The Government is anxious to get foreign capital interested in mining, and in consequence the mining laws are very liberal. The greatest drawback to development is the scarcity of labor and the depreciation of Nicaraguan currency. This can perhaps be overcome by raising wages and thereby attracting workmen

Map of Nicaragua.

from Honduras and Salvador. The present scale is as low as in the Far East. Laborers get \$1.40 paper per day; miners, \$2.25; trammers, \$1.90, of which they pay 40c. paper for food. The present rate of exchange makes the paper dollar worth about 10½ to 11c. gold; a miner on day's pay, therefore, makes 25c. gold per day. On contract he can make \$3 to \$5, or about 33 to 35c. U. S. currency.

The only tax on the industry is an export duty on gold, amounting to about 85c. gold per fine ounce. This duty is payable by means of bonds issued by the Government for purposes of paying taxes. These bonds must be bought from the holders, who are usually speculators, and this to some extent introduces an element of uncertainty. President Zelaya is the most broad-minded of the Central American presidents, and has shown himself the friend of foreign capital. If he appreciated how distasteful it is to the mines to pay a tax in that way, he would undoubtedly have established a more equitable method. Many of the mining companies object to the gold tax. In itself the tax is not objectionable, so long as it is not exorbitant, and is fixed, but foreign capital wants to be assured of stability. There are enough variables connected with mining without the fluctuation of political and economic conditions. The Leonese mine is getting ready to operate on an extensive plan, and another twelve months should make a big mine of it.

WASHINGTON.

Senate Tariff Changes.—Mineral Lands.—California Debris. — Mine Rescue Work.—Schools of Mines.

The work done by the mining interests, especially the protest of the lead-ore producers of Idaho, Utah, Colorado, and Nevada, had an effect, as is seen in the Senate amendments. The tariff bill will probably pass in the amended form. The paragraph referring to lead is as follows: Lead-bearing ore of all kinds, 1½c. per lb. on the lead content; lead dross, lead bullion or base bullion, lead in pigs or bars, 2½c. Lead in sheets, pipe, shot, glaziers' lead, and lead wire, 2½c. The provision regarding zinc is: Zinc ore and calamine, 1c. per lb. on the zinc content. Zinc in blocks or pigs, 1c. per lb.; in sheets coated or plated with nickel or other metal, 1½c.; old and worn out, fit only to be re-manufactured, 1c. Iron ore is taken from the free list. Iron in pigs, spigels-eisen, ferro-manganese, wrought and cast scrap-iron, and scrap-steel, \$2.50 per ton. Alumina, hydrate of, or refined bauxite, containing not more than 64% alumina, ½c. per lb.; more than 64% alumina, 0.7c. The duty on baryta, including barytes earth, unmanufactured is reduced from \$1.50 to 75c. per ton. Sulphur, refined or sublimed, and brimstone, advanced beyond the original condition as mined, \$6 per ton. The duty on plaster rock or crude gypsum is reduced from 40 to 20c. per ton. Aluminum, aluminum-scrap, and alloys of any kind in which aluminum is of chief value, crude, 7c. per lb.; in plates, sheets, bars, and rods, 11c.; barium, magnesium, sodium, and potassium, and alloys of which said metals are the component material of chief value, 3c. and 25% ad valorem. Antimony, as regulus or metal, 1c.; antimony ore, stibnite and matte containing antimony, 1c. on the antimony content. Chrome or chromium metal, ferro-chrome or ferro-chromium, ferro-molybdenum, ferro-phosphorus, ferro-titanium, ferro-tungsten, ferro-silicon containing more than 15% of silicon, ferro-vanadium, molybdenum, titanium, tantalum, tungsten, or wolfram metal, valued at \$200 per ton or less, 25% ad valorem; valued at more, 20% ad valorem; ferro-silicon containing not more than 15% silicon, \$4.

William H. Andrews has introduced in the House a bill which provides that hereafter all gold, silver, and quick-silver deposits, or mines, or minerals of the same, on lands embraced within any land claim confirmed or hereafter confirmed by the decree of the Court of Private Claims, and which did not convey the mineral rights, are to be declared free and open to exploration and purchase under the mining laws of the United States. The bill contains the proviso that before the locator begins condemnation proceedings for the property he shall tender to the owner of the land the sum of \$2.50 per acre in full payment for the surface ground, and the receipt of this sum shall authorize the immediate entry of the locator on the land. Another bill authorizes the Secretary of the Interior to sell any of the unappropriated non-mineral desert public land for \$1.25 per acre. The money derived from such sale is to be placed to the credit of the Reclamation Service. Duncan E. McKinlay, of Santa Rosa, California, has introduced a bill appropriating \$400,000 to carry out the plans of the California Debris Commission on the Sacramento and Feather rivers.

Stations for the training of miners in rescue work have been established by the Frick Coke Co., which employs 30,000 men at Connellsville, Pa.; the Consolidated Coal Co., of Maryland, at Fairmont, West Virginia; the Pittsburg Buffalo Coal Co., at the Marianna mine in Pennsylvania. This is a direct outcome of the demonstrations in rescue work being made by the Technologic branch of the United States Geological Survey. Senator Dick of Ohio, chairman of the Senate committee on mines and mining, has introduced a bill to apply a portion of the proceeds of the sales of public lands to the endowment of schools or departments of mines and mining. Each school is to receive next year, if the bill become a law, \$15,000, with \$1000 additional each succeeding year until the appropriation reaches \$25,000. The money is to be spent for instruction, research and experiment. Representative Richard W. Austin, of Knox

ville, Tennessee, has introduced a bill asking for the establishment of a mining experiment station at Knoxville, Tenn. This is one of many bills providing for the assaying of minerals by the United States Government in behalf of citizens. A geologist and chemist would have charge of the station. Senator Heyburn of Idaho proposes the payment of a tax of 10c. per acre yearly on all land held by any corporation, association, or person, which is held in connection with the conduct of any interstate business, or from which any article entering into interstate commerce is taken. A second bill provides that all corporations, persons, or associations holding lands in excess of 1000 acres shall pay an annual tax of 10c. per acre on such excess.

Simon Guggenheim, Senator from Colorado, could not keep out of the Western land question, and yesterday introduced a bill giving prospectors and miners the right to enter any of the forest reserves to locate claims and acquire title to them under the laws the same as on any of the public lands. The bill also provides that duly incorporated canal, ditch, or reservoir companies shall have the right-of-way through forest reserves and upon all public lands. Mr. Guggenheim also introduced a bill providing for instruction in forestry in the colleges of agriculture and for experiments in forestry in the agricultural experiment stations.

GOLDFIELD, NEVADA.

March Output.—Consolidated Production.—April Yield.

Official returns from high-grade ore shipped to the smelters by the Goldfield Consolidated Mines Co. during March show net earnings materially in excess of the estimates made by J. K. Mackenzie, manager. The expense of production has been reduced from \$6.31 per ton in February to \$5.85 in March. The detailed figures are: Number of tons mined, 19,503; number of tons milled, 19,150; number of tons shipped, 352; gross earnings, \$1,081,872; gross expense \$117,543; net earnings, \$964,329; net returns from ore shipped, \$215,599. Expense per ton: mining, \$3.43; milling, \$2.32; transportation, \$0.103; total, \$5.85. In the mining expense is included new development, salaries, office and legal expenses. The cost of treatment in the new mill is now \$2.005 per ton. Last year the expense of mining was given as \$6.14 per ton, and milling \$7.14. Dividend checks, more than 5000 in number, will be mailed on April 30. This dividend will entail the distribution, at the rate of 30c. per share, of \$1,063,803. The output for April will exceed the yield for March. Shipments of high-grade ore from the Hampton stope have been resumed at the rate of a car daily. Three cars which sampled \$700 per ton have been shipped. No regular clean-ups are made at the Consolidated mill, and until final returns from the Mint are available, results for any given period can only be estimated. The estimates thus far made by the management are shown to have been conservative.

With only a portion of the bullion returns received, the output of the mines and mills of Goldfield for the first 14 days of April is estimated at more than \$900,000 gross. This includes 9600 tons of \$45 ore treated by the Consolidated Co., besides 320 tons of concentrate, valued at \$300 per ton, which had been stored awaiting treatment; a total yield from the company's operations of \$528,000. The Florence Goldfield mill treated 1500 tons, valued at \$25 per ton. The Nevada Goldfield mill handled 1500 tons of \$50 ore, including a daily output of 90 tons from the Combination Fraction mine. The samplers of the Western Ore Purchasing Co. handled 1600 tons, of a value of \$165 per ton. The sampler's figures include high-grade ore from the Florence mine, the value being estimated at \$50,000. The high transportation and smelter charges will greatly reduce the net profits on this ore.

The Daisy mine is developing ore of excellent quality at three horizons, and the cross-cut at the 500-ft. level will soon reach the cross-fissure in which the richest ore of the Diamondfield district has been found. In the meantime the main shaft is being rapidly sunk to the 700-ft. level, and daily shipments are being sent to the samplers, the ore averaging about \$150 per ton.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Metallic sulphides are soluble to a slight degree in ordinary rain-water. This solubility is greatly increased where one sulphide is in the presence of another.

An acre-foot of water is the quantity which will cover one acre to a depth of one foot, 43,560 cu. ft., or 325,857 U. S. gal. This is equivalent to a stream-discharge of 0.5042 cu. ft. per second.

Aluminum is manufactured by electrolysis with carbon electrodes of aluminum oxide held in solution in a fused bath of cryolite and fluorspar. Works controlling 120,000 hp. are now engaged in its manufacture. Approximately 4 hp. per year are needed per ton of metal produced.

Germs find favorable conditions for growth underground, and sanitary precautions should consequently be taken with scrupulous care. Typhoid fever germs, once introduced into a mine, are difficult to eliminate. Sanitary closets should always be provided. These should be taken to the surface and cleansed daily.

Commercial sulphuric acid always contains many impurities, chief among which are arsenic, antimony, lead, copper, iron, and even bismuth and tellurium. These impurities may be thrown down by passing through sulphuretted hydrogen. Acid made from Mississippi Valley ores is generally free from arsenic; this gives them an advantage at smelters where the acid is recovered.

Illuminating gas requires for its manufacture an expensive plant. Coupled with this is an equally expensive system of distributing mains. The capitalization of gas plants is necessarily high, and the fixed charge to meet interest requirement is the largest element in the sale-price of gas. It is because of this, as well as the essentially non-competitive nature of the business, that the cost of gas is often underestimated.

Vacuum-pan evaporation is evaporation facilitated by producing a vacuum above the fluid to be volatilized. It is always aided by applying heat, either externally or through steam coils. The method is used in salt and sugar manufacture and in the chemical industries generally. It is more economical to utilize heat-energy by developing power and applying it through a vacuum pump. This creates vapor-tension and promotes evaporation.

Arsenic is found commonly as realgar and orpiment, both being sulphides, and abundantly as mispickel (FeAsS), and is associated with sulphur and antimony in a great variety of minerals. It occurs rarely as an oxide in the processes of alteration. The sulphides of arsenic are insoluble in water, but the disulphide is dissolved slowly in alkaline sulphide solutions. The trisulphide, however, passes into a colloidal state which is soluble in water.

The Cornwall has the largest output of any iron mine in the Eastern States, and was fifteenth in rank in 1907. It has yielded 20,000,000 tons of ore from practically one orebody. The mine is in Lebanon county, Pennsylvania. The ore is essentially magnetite, though pyrite is present in sufficient abundance to require that the ore be roasted. The ore occurs in sedimentary rocks near the contact with masses of intrusive diabase.

Copper sulphides are far more stable than iron sulphides, and resist oxidation to such an extent that it is probable chalcocite will not yield except through ionization in the presence of certain salts in solution. Ferric sulphate forms readily, however, and reacts according to the following equation:

Ferric sulphate is an energetic solvent for gold, as is cupric sulphate also. Both salts readily reduce to the 'ous' state, and precipitate dissolved gold.

Quartz-glass, which is pure silica fused in an electric furnace, possesses the advantage of being free from any alkaline ingredient, of possessing a melting point 800°C . higher (1800 to 2000°C .) than that of ordinary glass, and in not being fractured by sudden changes of temperature. Red-hot quartz-glass may be plunged into cold water without breaking. It is neither hygroscopic nor soluble in acids, and alkaline solutions affect it less than they do common glass. It is now used for combustion tubes, beakers, and evaporating dishes in laboratories.

On the Comstock lode the main fissure is 10,300 ft. long. The valuable ore was found in it and in the southeast branch. The dip of the vein varies, as does also the strike. At the Belcher mine the dip is 32° , at the old Sierra Nevada shaft 51° . The biggest bonanza, that of the Con. Virginia and California mines, was in the branch fissures of the hanging wall. The Sutro Tunnel, cutting the vein at 1865 ft., drained the upper workings, and water from the deeper workings was pumped up to it. The deepest mining was at 3080 ft. in the Yellow Jacket, at 3250 ft. in the Combination shaft, and at 3308 ft. in the Mexican. This was in 1884. The productive portion of the lode was mainly above the Sutro Tunnel, the deeper exploration proving disappointing.

Mine-waters frequently receive accessions from mills, works, and town-drainage in the vicinity, which could be trapped and carried off. The connection between the source of contamination and the mine is often difficult to establish. A convenient means is to introduce lithium chloride into the waters suspected of seeping into the mine. A gallon of concentrated solution introduced by constant drip through a 24-hour period will usually suffice. Samples of the mine water should be taken at regular intervals for a number of days thereafter, evaporated, and the residue tested spectroscopically for lithium. This is sensitive to one ten-millionth of lithium in the salt examined. The mine-waters, of course, must be previously tested for that element, but it is a substance rarely found in natural waters.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Panama Canal.

The Editor:

Sir—In your issue of March 27 were some personal animadversions made by Cassius E. Gillette. I regret these were published before being submitted to me, so that my position might have appeared in the same issue. The intimations of political chicanery are unworthy of notice, but in behalf of honorable men living and dead, as well as of the profession, it seems that the erroneous statements which have been made impugning the character and motives of my associates demands a refutation. Your correspondent, like myself, is a graduate of the West Point Military Academy and ex-member of the Corps of Engineers, and has consequently had the same preliminary training. He calls attention to a discussion relative to harbor-bar improvements, and to a system which I have developed whereby a portion of a single jetty is made to scour out a channel by utilizing the forces of nature, thus producing reasonably self-maintaining works at less than one-half the cost of the older Continental system. This invention and discovery was endorsed by competent experts in scientific societies and by juries of international exhibitions. In 1887, it was submitted to the U. S. Board of Engineers for use in this country, accompanied by the request that it might be tested at any point which the War Department might deem suitable, without expense to the Government, save for results secured. This body filed a report condemning the system as having no value and containing nothing new. I then applied for patents as a basis for the organization of a construction company to make guaranteed tenders to the Government to create channels at less than half the cost of the existing plans, and to take compensation only for the depths as secured. There was nothing like "A central trust in New Jersey, with local companies . . . which could have a secret membership covering local politicians capable of influencing the National Government to adopt the Haupt plan." After thus drawing upon his imagination as to the possibilities of crookedness in the introduction of a system so highly endorsed and giving such great promise of success and economy that Congress did finally adopt it, in spite of the strenuous opposition of the Corps of Engineers, your correspondent relieves me from the intent to err by stating, "I really doubt if Mr. Haupt appreciated the enormity of his proposition." He then proceeds to cite another hearsay story to demonstrate my incompetency as a member of the Isthmian Canal Commission. He states that I had objected to the unit-price as being too high, and that "nine pairs of astonished eyes were turned on Mr. Haupt at this, and he withdrew his suggestion." There is no truth in the story, and it may illustrate the unpre-

liable nature of the communication to add that as there were only nine members on the Commission, I must have been one of those who looked on myself in astonishment. The facts are that each engineering member submitted a schedule, in writing, and the averages were then tabulated and discussed.

The Reaction Jetty Co., which was composed of experienced engineers, lawyers, and men of affairs, who had faith in the merits of my plans, made tenders for the removal of the bars at the mouth of the Mississippi. The Government plan called for an expenditure of \$13,000,000, with an annual maintenance charge of \$390,000, but with no guarantee of results. The company proposed to put up bonds for the faithful fulfilment of its contracts, if granted, and to procure a 35-ft. channel for \$6,000,000. This had the effect of bringing the Government estimate down to the same figure, but in doing so, and in order to reduce cost, the plans were so modified as to place the jetties so far from the channel as to render them almost useless. It also compelled resort to dredging, despite which the channel has not been scoured, and larger dredges are now being built. The bar meantime has moved gulf-ward, and is now more than a half a mile beyond the works, which are to be extended at additional cost. A similar guarantee was submitted for the mouth of the Columbia river at a cost of \$2,500,000, which was referred to a Board of Engineers of which your correspondent was a member. After some eight months of consideration the Board finally made a report from which was suppressed all reference to the company's proposal, and the company was denied the right to review or even to examine the said report, although the Board was a special one appointed to consider and report upon its proposition. Your correspondent is stated to have remarked to his superior officer, in the presence of the counsel of this company, that to entertain favorably such a proposal as the company had made would be revolutionary, and it should not be done; or words to that effect. He had not forgotten the experience of James B. Eads in opening the South Pass of the Mississippi on a similar basis, which was so great a relief to the country, but which had been opposed by the Corps of Engineers. The above few instances out of many are cited to illustrate the conditions which have resulted, as our late energetic president has stated, in the work on our rivers being "largely negative." In this valedictory he said: "We have spent hundreds of millions upon our waterways," and he deplores, "the utter waste caused by the methods which have hitherto obtained," adding, "We should have a new type of work and a new organization for planning and directing it. The time for playing with our waterways is past. The country demands results."

LEWIS M. HAUPT.

Philadelphia, April 2.

The Editor:

Sir—I read yesterday in a copy of the MINING AND SCIENTIFIC PRESS of March 27 a communication signed by Maj. Cassius Gillette. Without going into any discussion of the subject matter of Major Gillette's communication, I wish to take exception to

his reflections concerning Professor Haupt. I was a student at the University of Pennsylvania when Professor Haupt was head of the Department of Engineering; I was afterward associated with him as instructor and assistant professor; and for some years after my graduation from the University was also his business partner; all of which connections have given me an intimate knowledge of his character, and I desire to state that in all my associations with him I found nothing that would indicate any ground for the grave charges which Major Gillette's statements by innuendo and insinuation seem to imply.

BENJ. FRANKLIN.

Philadelphia, April 7.

The Editor:

Sir—In your issue of March 27 you publish a letter from Cassius E. Gillette reflecting upon the honesty and professional ability of Lewis M. Haupt. I do not know what has inspired this attack. I have known and respected Mr. Haupt for over twenty-five years. Whatever may be his faults, this is the first and only time I have ever heard his honesty questioned; I am sure no one who knows him well will believe these statements.

I dislike public controversies, and it is only a sense of loyalty to an old friend that impels me to indite this communication. I understand that Mr. Gillette claims to belong to the mining engineering profession, although I have not understood that he has been accorded recognition as such by the reputable old-line members of that branch of the engineering fraternity. As I do not know Mr. Gillette personally I have no means of judging his ability in this respect, except what I can glean from his reports, which is far from favorable.

Mr. Gillette is, I understand, a West Point Military Academy graduate, and was formerly in the Corps of Engineers. Some years ago he came to Philadelphia to install a system of sand filtration, and in order to accept a supposedly permanent position under the City he resigned from the Army. It is no reflection upon him that he lost this job through political exigencies. That he should then undertake to earn his living as a civil engineer is quite natural and proper; and even if he should subsequently become a mine promoter, that is a perfectly legitimate action, provided he gives up engineering. The curriculum at West Point does not, I understand, contemplate preparing men for geological and mining work, and Army engineers, as a rule, are not expected to develop into geologists and mining engineers.

F. LYNWOOD GARRISON.

Philadelphia, April 3.

The Editor:

Sir—The contribution by Cassius E. Gillette under the above heading, in your issue of March 27, seems to cast doubt upon the professional ability and honesty of Lewis M. Haupt. I am surprised and pained that you should publish the article without giving Mr. Haupt an opportunity to reply in the same issue. From a personal acquaintance of more than 35 years

I know that Lewis M. Haupt stands too high in the public esteem to be reached by innuendoes of this kind, no matter how cunningly they may be worded. While I do not know Cassius E. Gillette, I was astounded at this article, for I believe Gillette and Haupt are both West Point graduates, and I presumed professional courtesy should have made such an attack impossible. My astonishment was such that I felt impelled to enquire into the standing of the author of that article to learn what weight should be accorded to his utterances. Not being personally acquainted with him, my information is based mainly upon hearsay. From enquiries I have made, I am informed that he resigned from the Army Corps of Engineers some years ago, and recently has maintained an office in Philadelphia as 'Consulting Engineer', and has accepted a number of engagements to make geologic and mine examinations, and to advise upon the value, development, and management of mining properties. After somewhat careful enquiry, I fail to learn that he has had previous mining experience which would qualify him for such work.

It seems to me that some way should be provided whereby the qualifications of those practising as mining engineers may be readily determined. The subject is one that could properly be taken up and discussed by the Mining and Metallurgical Society. The uneducated pretender is not especially dangerous, either to the public or to the profession, but if men of education, especially of engineering education, having the prestige of prominent social or business connections, are permitted to practise a profession for which they were not trained, then that profession or the public, or both, must surely suffer.

Aside from the apparent reflections upon Lewis M. Haupt, the article in question is remarkable for the impertinence and audacity of the author in presuming to express a patronizing approval of your editorial, 'ideas on mining geology and mine finance'.

H. M. CHANCE.

Philadelphia, April 10.

The Editor:

Sir—Probably no engineer enjoys more fully or more deservedly the confidence of his colleagues in his integrity than does Lewis M. Haupt. Indeed, those of us who have known him for a quarter-century or more have come to regard him as one of those persons who are "so upright that they lean over backward." It must therefore be a surprise, to Mr. Haupt's many friends, to read, in your issue of March 27, a communication from Maj. Cassius E. Gillette, under the heading, 'Panama Canal', closing with a paragraph which, at first sight, appears to reflect very seriously, not only upon Mr. Haupt's professional equipment, but also upon his moral character; and they will be correspondingly relieved to find, upon a scarcely less cursory review of the paragraph, that it is, on the whole, rather complimentary to Mr. Haupt, and in only one matter derogatory.

Major Gillette says that he is quite familiar with Mr. Haupt's personal equation, including his capabilities as an engineer. This, of course, involves no reflections upon Mr. Haupt, notwithstanding that

Major Gillette's familiarity with the personal equations of others (through which he has become noted) has sometimes resulted unfavorably to those equated. Referring to a discussion between Mr. Haupt and himself, Major Gillette says: "a careful reading of the matter would repay you for the time involved." In justice to the Major, we must assume that his applause is not intended exclusively for his own share of the discussion. Major Gillette tells us that "Mr. Haupt organized a company to promote his peculiar 'jetty theory,'" and that "the plan was to have a central trust in New Jersey, with local companies wherever harbor improvements were to be made by the general government." This, of course, is merely to the credit of Mr. Haupt's business enterprise and of his faith in the soundness of his theory. Major Gillette remarks that "these companies could have a secret membership, covering local politicians capable of influencing the national Government"—a statement which, in its conditional form, is applicable to companies in general. Major Gillette doubts "if Mr. Haupt appreciated the enormity of his proposition," thus paying at least negative tribute to Mr. Haupt's moral sense, whatever the enormity may have been.

Major Gillette is reliably informed that "there were nine pairs of astonished eyes turned on Mr. Haupt," when he protested against the adoption, by the Isthmian Canal Commission, of certain unit figures (which he thought were very high), on the ground that such adoption would "kill the whole canal proposition," and that Mr. Haupt thereupon "abandoned his suggestion." This charge, of having abandoned, under fire, a perfectly proper suggestion, is the only one I find in Major Gillette's communication, and those who know Mr. Haupt will find it difficult to picture him abandoning his colors, even though ninety-and-nine pairs of astonished eyes were turned upon him.

JOHN C. TRAUTWINE, JR.

Philadelphia, April 8.

Zinc Ore from Mexico.

The Editor:

Sir—In your editorial of March 24 on the production of zinc, you state that "the increase of 25% in importations of ore from Mexico in one year challenges attention."

The MINING AND SCIENTIFIC PRESS is distinguished for its accuracy, but in this instance it would appear that a mistake has been made. The Fiscal Bulletin published in Mexico by the Department of State in 1908 gives the exportation of zinc ore from Mexico as follows, for the 12 months ending June 30, 1907:

	Metric tons.
To Germany	2,284
To Belgium	12,669
To United States	82,611
Total exports	97,567
Value	P2,010,408

From ad. zinc sheets of the Fiscal Bulletin for 1908-'09, kindly forwarded to me from Mexico, the

exports of zinc ore for the 12 months ending June 30, 1908, are given as follows:

	Metric tons.
To Belgium	4,282
To United States	37,877
To England	1,180
Total	43,339
Value	P888,474

You will note that instead of an increase in the exportation of zinc ore from Mexico, there was a decrease to less than one-half of that of the year before. I have no accurate figures covering the production for the latter half of 1908, but know that there was no increase in the tonnage shipped such as your figures would indicate.

JAMES W. MALCOLMSON.

Kansas City, March 30.

Lake Copper.

The Editor:

Sir—We have had the impression, on what appeared to be good authority, that the Lake Copper produced by the Calumet & Hecla Mining Co. sold at a better price than that of any other Lake company. The following taken from elaborate tables, furnished by the respective companies in the suit of A. S. Bigelow v. the Calumet & Hecla Mining Co., show that the product of this company and that of the near-by Osceola sold at practically the same figures in 1905 and 1906:

		Average gross price,	
		Pounds.	cents.
Deliveries in 1905.....	C. & H.	74,045,970	15.54
	Osceola	16,708,117	15.46
Deliveries in 1906.....	C. & H.	94,336,600	18.406
	Osceola	22,174,669	18.57
Deliveries in 1907	C. & H.	34,756,200	21.82
	Osceola	6,776,295	21.607
All sales, 1905-06	C. & H.	203,168,720	17.945
	Osceola	45,659,081	17.898
All deliveries, 1905-06..	C. & H.	168,412,570	17.14
	Osceola	38,882,786	17.23

It will be noted that part of the copper sold in 1906 was not delivered until 1907, and that the total sales for the two years is to be made up by adding the copper delivered in 1907 to that delivered in 1905-06.

L. S. AUSTIN.

Houghton, March 22.

What Is an Ore?

The Editor:

Sir James F. Kemp's definition of 'ore' in your issue of March 20 seems to me still open to one objection. I feel great delicacy in offering any sort of criticism on anything written by one of such recognized ability, and particularly as I have always regarded a remarkable clearness of language as one of the striking characteristics of Professor Kemp's writings; but the term 'profit', as used in his proposed definition, seems to need either an explanation or a substitute.

Suppose a miner sells a lot of ore for \$1000. The cost of production is first estimated at \$990. Then

it is ore. But some more critical accountant calls attention to the fact that no items of interest on the investment and amortization have been included, which might bring the cost above \$1000. If so, it is not ore. On amortization it is necessary to consider all prior production and the remaining value of the mine. This would likely require years to determine. Must we wait for a future generation to decide the name of the thing we are dealing with? Suppose it be definitely decided that, after gathering every item chargeable, the cost of production amounts to \$1000; yet that sum went to benefit somebody: if both the mine and the smelter lost money in handling it, still the railroad may have made a profit exceeding the combined losses of the mine and the smelter. If the mine, the railroad, and the smelter all lost by the operation, still it may be that the wages of the employees of all three added to the wealth of human society—that the net amount so added exceeded the combined losses. Again, a miner, in driving along a vein to reach a known ore-shoot, encounters and saves some material which he sells at \$5 per ton. It has cost him \$10 per ton to mine and market it, but he would have driven the same drift had it not produced a pound of saleable rock. Then the \$5 per ton for whatever he could market was just that much salvage. In other words, his necessary dead development expense is reduced by whatever returns he can secure from any sales of material which has to be broken in the progress of the work. In every large mine, having a complicated system of veins, 'development ore' is a regular item in the accounts. In this is classed all of the product which falls below the combined cost of mining, transportation, and reduction and above the combined cost of transportation and reduction, but it is valuable and goes to the smelter. Take another illustration: A miner has to choose between driving a cross-cut adit 500 ft. through entirely barren country, costing \$5000, or following an unprofitable portion of the vein for 1000 ft., costing \$10,000, to reach a known pay ore-shoot. He estimates that the 1000 ft. of drift on the lean vein will yield \$6000 in returns from material that can be marketed. Thus he deliberately plans to expend \$10,000—\$4000 more than the estimated returns—because that will amount to \$1000 less than the 500-ft. cross-cut. The case of the pile of magnetite purchased at a bankrupt sale is another example. These examples represent a phase of mining not at all extraordinary. In all cases something was produced which was not profitable, yet entered into the commercial activities of the world and benefited someone, and that thing must have a name. I think it should be 'ore', and I believe that a miner, a jury, or a judge would so pronounce it, and 'use is the law of language.'

The definition might be modified thus: In a scientific sense an 'ore' is a metalliferous mineral belonging to the group of those which have commercially yielded the metals to the world's wealth. In its technical sense an 'ore' is a metalliferous mineral or an aggregate of metalliferous minerals, more or less mixed with gangue, and capable of being won as a commercial operation, adding in any way to the

world's wealth. The last phrase may be unnecessary. Or: in its technical sense an 'ore' is a metalliferous mineral or an aggregate of metalliferous minerals, more or less mixed with gangue, in sufficient quantity and consistence to institute commercial operations. Instead of eliminating the word 'profit', some might prefer to introduce an explanatory clause to cover such cases as those above mentioned; but such an explanation would be tedious and beset with serious difficulties. No one will belittle the difficulty of giving a definition that is both satisfactory and concise.

V. G. HILLS.

Denver, March 27.

Mining Cost in Mexico.

The Editor:

Sir—The enclosed cost-sheet may be of interest to the general mining public as showing what development work is done for at the San Francisco mine in southern Mexico, and you are welcome to publish the figures as given. All work is done double-handed and under contract. The vein is hard quartz, and all winzes and raises have a cross section of 1.4 by 1.3 metre.

DEVELOPMENT COSTS IN OAXACA.

Development for month, metres.....	134.95
Dynamite used, kilograms	471.59
Fuse used, metres	1570.00
Caps used, 5X	2298
Candles used, native dip	4271
Direct cost—Supplies	₱ 754.10
Labor	1957.96
Total	2712.06
Direct cost per metre—Supplies.....	5.79
Labor	14.52
Total	20.11
Total cost per metre	36.90
Equivalent cost per foot (U. S. Cy.).....	\$5.62

A cross-cut tunnel was started March 1, 1908, and to March 1, 1909, the advance was 240.00 metres, an average rate of 0.65 m. or 2.15 ft. per day. The total cost, everything included, was ₱7567.45, or ₱31.50 per metre, or \$4.80 gold per foot. The cross-section of the tunnel is 2 by 3 metres, and the material penetrated is augite andesite—fresh and hard.

Mechanical Elevator.

The Editor:

Sir—I was much interested in your description of the mechanical elevator in use on Bonanza creek, Yukon Ter., and am disposed to believe that this or some similar apparatus will prove widely useful. Would you mind stating who built this elevator and from whom it may be obtained?

E. D. F.

Denver, April 3.

[The elevator in question was built by the Link-Belt Co. and supplied, we believe, through the Chicago office.—EDITOR.]

In small power plants of the size representing the average in use in factories, a gas power plant is able to save so much coal that it can produce power at much less total cost than the steam-power plant.

MINING IN NORTHERN CHINA.

Written for the MINING AND SCIENTIFIC PRESS
By F. L. COLE.

Mining, in other than native fashion, is an unimportant industry in northern China, although the regulations that apply to northern China apply to the whole Empire. The mines north of the Yangtze river, at present worked solely by foreigners, joint foreign and Chinese companies, or Chinese owned and under foreign management, number only about a dozen, and nearly all of them are coal mines. The few concessions that have been granted to foreigners in the past have had a more or less checkered existence politically, and at present it is not possible to obtain concessions on the liberal terms heretofore granted; in fact, it is difficult to obtain them at all.

Under the terms of the treaties made by China with Great Britain and the United States in 1902-04, China agreed within a year from the dates of those treaties to make mining regulations that would give reasonable opportunity for the investment of foreign capital. Various regulations have been made from time to time, also special ones for special concessions, and in 1907 regulations consisting of 74 articles and 73 supplementary articles appeared. Against these regulations, however, a protest was made by the Ministers of the different Powers at Peking, and it is stated that assurances were given by the Chinese government that better ones would be issued. These regulations, although particularly absurd and impossible, are practically in force today as far as native mines are concerned, and to some extent they also affect foreign interests. Excellent mining regulations have been submitted by capable foreign advisors, but up to date the Government has made no definite move toward making opportunities for foreign investors on reasonable terms without prolonged negotiations.

The Chinese government claims all minerals, irrespective of the surface rights of land-owners, and applications for mining rights have to pass the district and provincial authorities as well as the Imperial Board of Agriculture and Commerce, which at present has charge of mining affairs, and, in the case of foreign interests, the Imperial Board of Foreign Affairs also. The opportunities for obstruction, alteration, and the division of the spoils are endless; at the outset these constitute barriers enough to discourage the most optimistic, but those who have labored along those lines have generally succeeded in time in obtaining a satisfactory agreement.

Time is no object in China, the hurry bacillus has not reached there yet, and anyone contemplating mining had better go prepared for a long and expensive campaign of uncertain results. In the case of a coal mine to supply a certain railroad, both of which would contribute to the Government revenue, it took three years to settle an agreement for a foreign loan to operate the mine under joint foreign and Chinese management. Meanwhile the railroad was built by a loan from the same foreign syndicate and coal had to be obtained elsewhere. In another case of a concession granted to a foreigner for a coal

mine, it took over five years to secure a satisfactory agreement for its operation. However, the foreigner commenced work before the negotiations were finished, thus doubtless hastening their conclusion.

The question of security for the investment of foreign capital for mining in China is an important one, as no foreigners, except missionaries, can own land outside of a treaty port. The fear of foreigners securing a foothold under the pretext of mining is always evident. At present there are no regulations that provide for any security, except in the cases of some individual concessions where rights extend over a period of years and the Government guarantees that the rights shall be upheld. Where loans have been made for railroad construction the principal and interest have been guaranteed by the Government, and also in some cases by the loan companies being allowed to operate the roads for certain lengths of time.

The Chinese have not been particularly well treated in many of their earlier agreements with foreigners, and hence are more conservative than they doubtless would have been had their first experiences been different.

The case of the absorption of the Chinese Engineering & Mining Co. (Kaiping coal mines, in Chili Province) by a British syndicate during the Boxer trouble has caused much hard feeling toward foreign investors generally. The Chinese have only a small portion of the shares of this company, and no voice in the management, though had the company been organized on joint lines, it is questionable if it would have been the prosperous undertaking that it is at present.

The general idea of the average Chinese official regarding a mine is that it is a hole in the ground which has some machinery on it for which good commissions are to be made in the buying, and that at any time this hole can be made to produce hard money in the shape of royalties or presents, regardless of its condition. The fact that a certain expenditure has to be made to put a mine in condition for production and that the output is not all clear profit, are mere minor considerations. Every industry in China has to support the greatest possible number of people, and everything that has to pass through various hands must leave its share in each.

Those foreigners who have been successful in obtaining mining rights in northern China have been helped by their respective governments; they have been principally British and German. The policy of the American government at present is to offer but little assistance to prospective investors. Without official help any undertaking is handicapped. The British and German governments are notably active in helping their subjects to obtain concessions of various kinds. It is expected that proper mining regulations will be forthcoming soon, but as five years have passed and the treaty obligations that were to have been fulfilled in one year are still in suspense, it is an interesting problem to juggle with. When satisfactory regulations do appear, a new field with great possibilities will be opened.

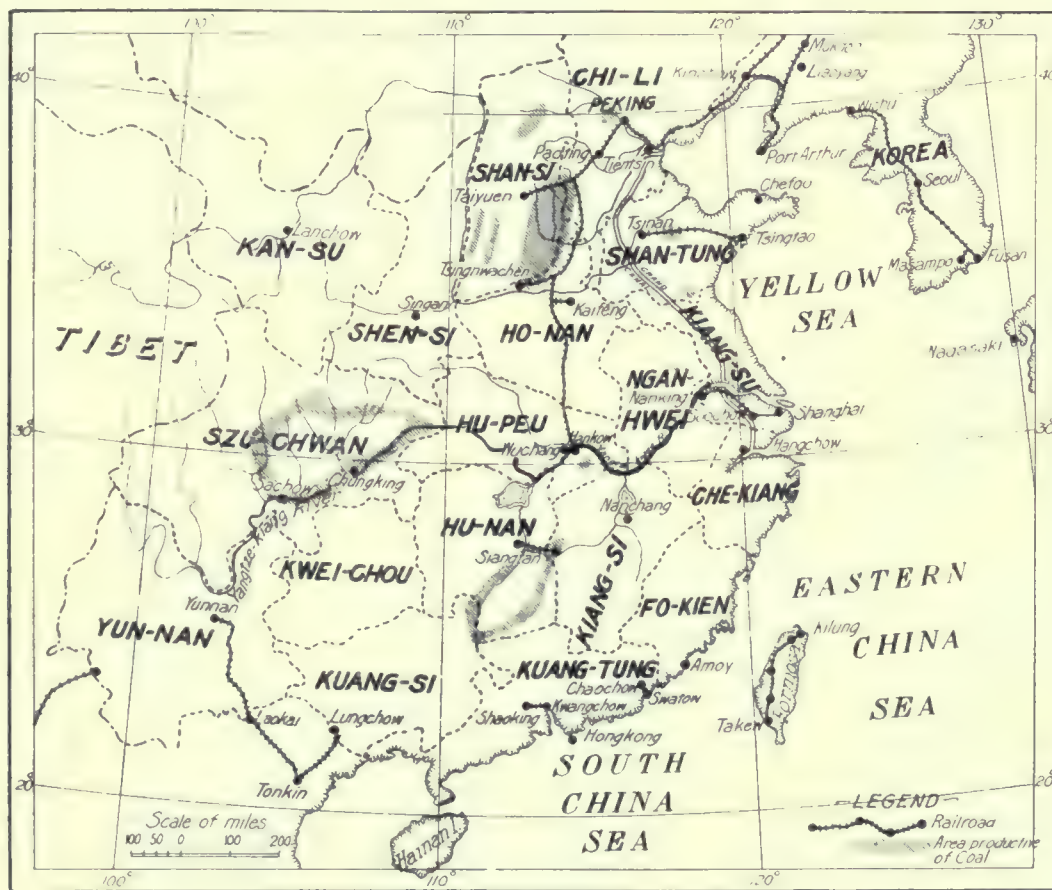

Chinese capitalists, as a rule, do not take kindly

to mining except when they are well acquainted with it, and then only in a small way, as the chances of their undertaking being absorbed by the Government are excellent, and they can use their money in safer ways. There is a tendency, however, at present for Chinese companies to open mines because the new railroads have given an impetus to coal mining. With the advance of railroad building we may look for an advancement in mining. Railroads are in fashion at present, as, so far, foreign money has been easy to obtain, and the handling of large loans has made competition keen for the important positions in railroad administration. When once the advantages of mines operated under foreign methods becomes a recognized fact there will be assured progress and opportunities for investment.

At present there is a growing demand for foreign

give advice regarding the needs of the particular mine, and some practical hints about the operation and management of both the machinery and the mine, the results would have been more sales and more mines. This is being done to some extent at present, with good results. Both the buyer and the seller are learning.

Coal is the principal asset of northern China, and it offers many opportunities for development, as the scarcity of other fuel makes a constantly growing demand. Railroad rates at present are very high, and Japan sells annually large quantities of coal to China. Very little iron has been found and worked, but the geological conditions are favorable in several provinces. Given iron, with the immense coal deposits and with the transportation afforded by the new railroads, together with the unlimited supply of good

Map of China.

engineering advice for Chinese mines, as up to date very few Chinese engineers have appeared with the necessary combination of theory and practice to achieve practical results. There are no keener business men than the Chinese bankers and merchants, and the rapid advance the country has made in the past ten years will no doubt have its effect upon mining in the near future.

There are many monuments of a mistaken policy, in the shape of old boilers and mining machinery, scattered over China, which have usually been sold by foreign merchants to Chinese who had but a vague idea of what their needs were, and the merchant cared less, as long as he could get his profits. If the merchant in many cases had been satisfied with a little less profit and had had an engineer to

cheap labor, there is a great future ahead for the industry. Even without iron there are many possibilities in manufacturing that will make China a big exporter of many things that are now being imported.

China is a well known buyer of silver and copper. Neither of these metals has been produced in quantity in the North, but there are known deposits of both that would doubtless pay to work. Gold is mined in many localities, but outside of the alluvial mines along the Amur river in northern Manchuria there are few places where it is produced on any scale. There are quartz mines that would pay if operated in a small way with foreign methods, and possibly some that would pay if operated on a larger scale. There are undoubtedly opportunities for

dredging and other methods of alluvial mining. It is practically impossible to obtain any definite idea of the mineral output, as such a small amount passes through any source making statistics available.

Manchuria has been generally looked upon for some years as being fabulously rich in minerals, but up to date, with the exception of one large and two or three small coal mines of an indifferent quality of coal, partly developed by Russians and now being developed and operated by the Japanese, under protest from the Chinese, there are no mining developments in progress in which foreign capital is interested, nor have any concessions been granted to foreigners since the late war. It is a significant fact that outside of the mines just mentioned there are no Japanese mining concessions in China.

According to the present mining regulations, it is possible for foreigners to obtain mining rights as equal partners with Chinese under joint management, but it is a slow process and, with the constant change of officials, not an attractive one, except under favorable conditions and with strong political backing. To those who have capital, influence, and patience there are undoubted opportunities.

Traveling in northern China is easy and comfortable, and when the foreigner remembers that there are some 400 million Chinese, and that to them their own ways and habits are the only ones, he has little or no difficulty. It is generally the fault of the foreigner if there is trouble. Transportation is good for the character of the country, the climate is excellent, and labor cheap and efficient.

There are many reforms needed to put mining on a sound basis. A topographical and geological survey of the mineral districts would be of great value and a fitting work for some of our benevolently inclined rich to undertake. There have been many foreign engineers and geologists in China, but the amount of available useful information relating to mining is small.

The general policy of the 'open door' has not so far succeeded in accomplishing much in the way of opportunities for mining. The Chinese have to be 'shown'; the present is a transition period of foreign innovation, but the way they have taken to foreign cigarettes, cotton cloth, kerosene, and machinery in the past few years is remarkable. The small number of American business houses in China is also remarkable. It is to be hoped that with the continued progress along other lines, mining will soon receive substantial attention from the government.

The cyanide assay for copper applied on the ores of Ely, Nevada, shows results which are as much as 0.126% too low unless the iron precipitate be re-dissolved. The precipitate was found to hold back 3.4% of the total copper present. The cyanide assay generally yields lower results than the iodide method.

A new index map of Alaska, showing areas covered by topographic surveys, has just been issued by the U. S. Geological Survey. On the back of the map is printed a list of the Survey's publications on Alaska, arranged geographically. These publications comprise 28 maps and 119 reports.

N. E. G., Red Rock, Arizona: No. 1, (a) gabbro, or diorite-porphyry; (b) copper-stained trap rock, probably diabase; No. 2, andesite, much altered and seamed with calcite; No. 3, quartz-calcite aggregate with hematite, malachite, and chrysocolla; No. 4, granite porphyry; No. 5, quartzite stained with malachite and possibly some chrysocolla.

The death is announced in Russia of Baron Horatio Ginsburg, who played a leading part in the development of gold mining in Siberia, and especially in the Lena region, where he amassed a vast fortune.

MINING METHODS IN THE NORTH.—IV.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

By the method of drifting, only the bottom layer of the gravel deposit was mined; any gold in the overburden remained untouched. The gold was not always concentrated on the bedrock, or even in the five or six feet immediately overlying, so that the

engine. The pay, on bedrock, was dug by hand with pick and shovel, and then taken in wheelbarrows to the dump. Later, the self-dumping bucket was introduced; this traveled on a steel rope and was pulled by steam-power; it served to raise the gravel 30 to 40 ft., so as to afford plenty of tailing-discharge.

Another method was to set sluice-boxes in the open-cut itself, wherever there was an outlet at the level of bedrock. In rare cases, where natural drainage from the open-cut was not available, the water was pumped and the tailing was hoisted from the end of the sluice-boxes. No man was permitted to dump tailing on his neighbor's ground.

On No. 15 Below Discovery on Bonanza creek, in the Yukon Territory, I saw a typical example of the open-cut method. The ground had been worked by 'drifting' several years ago and was thawed naturally to bedrock except for occasional patches of ice where water had gathered in old workings. This also had been thawed by stripping and subsequent exposure to the summer sun. First, the top 4 ft. of dirt is removed by means of a scraper operated by steam-power.

The scraper, guided by a man, is pulled forward and backward by steel ropes attached to a gin-pole. When the overburden has been re-

Open-Cut Method on Bonanza Creek.

method entailed waste. It was not complete. Also, there was danger of a collapse of the ground when the roof softened, by admission of warm air in summer or by penetration of surface water. Sometimes the mine caved, or the loosening of the ground was such as to increase the cost excessively. To the owners these delays might not be serious, but to the lessees it meant loss of valuable time. For most of the drift-mining was done by 'laymen', that is, men who worked the claim on a 'lay' or royalty. They were 'tributers' or lessees, contracting for the right to mine the ground on condition of paying a royalty to the owners. This royalty ranged from 25 to 60% on the gross yield. A 50% lay was common. As it meant giving the owner one half of all the gold extracted, it bore evidence both to the richness of the ground and the venturesome spirit of the operator.

To obviate underground excavation, the open-cut system was introduced. The overburden was removed with scrapers, pulled by horses or by a steam-

On Discovery Claim, Cleary Creek.

engine. The pay, on bedrock, was dug by hand with pick and shovel, and then taken in wheelbarrows to the dump. Later, the self-dumping bucket was introduced; this traveled on a steel rope and was pulled by steam-power; it served to raise the gravel 30 to 40 ft., so as to afford plenty of tailing-discharge. Another method was to set sluice-boxes in the open-cut itself, wherever there was an outlet at the level of bedrock. In rare cases, where natural drainage from the open-cut was not available, the water was pumped and the tailing was hoisted from the end of the sluice-boxes. No man was permitted to dump tailing on his neighbor's ground. On No. 15 Below Discovery on Bonanza creek, in the Yukon Territory, I saw a typical example of the open-cut method. The ground had been worked by 'drifting' several years ago and was thawed naturally to bedrock except for occasional patches of ice where water had gathered in old workings. This also had been thawed by stripping and subsequent exposure to the summer sun. First, the top 4 ft. of dirt is removed by means of a scraper operated by steam-power. The scraper, guided by a man, is pulled forward and backward by steel ropes attached to a gin-pole. When the overburden has been re-

the sluice-boxes. The fixed cable can be anchored as desired, with the progress of excavation, and is kept taut by a counterweight, so as to permit the carrier or bucket to run back by gravity after it has been discharged at the upper terminal. The sluice-boxes, set on a trestle, are 12 in. wide and have a gradient of one inch per foot, but the first one or 'mud-box' (into which the gravel is discharged) is inclined at 20 in. per 12 ft. and is 3½ ft. wide. The attendant lifts any large (more than 2 in.) pebbles by means of a fork into a car, which removes them to a distance. Of the gold obtained, two-thirds is arrested in the first sluice-box, 12 ft. long, and one-third in the next 20 feet.

From 2 to 2½ ft. of bedrock (soft schist) was being removed, by pick and shovel. The material is conveyed in wheelbarrows to the bucket, which comes to rest at a fixed spot. By the time the bucket has made a complete journey, to the dump-box and back, the men working in the open-cut have filled their wheelbarrows and proceed to trundle them, in turn. Thus, while the movement of the bucket is intermittent, work is continuous. The wheelbarrows serve for storage while the bucket is away. There were 12 men at work in the cut on each of the two shifts; of these, 10 were digging, one was picking drains in the bedrock, and another was tending the bucket. In addition, there were: An engineer at the hoist, a boiler-man, a blacksmith, a man at the dump-box, another that attended to the tail-race, and a foreman. Thus there were 18 men per 10-hr. shift, or 36 in all. Wages were \$4 and board, for most of the men. A few got \$5, and the foreman \$8, besides board.

In this way Andrew Horn was working this thawed deposit in Bonanza creek to a depth of 14 or 15 ft. Under such conditions it was profitable to exploit ground that yielded \$1 per square foot of bedrock or about \$2 per cubic yard. The stuff on bedrock ran 10 to 25 cents per pan, that is, \$15 to \$30 per cubic yard, for a thickness of 6 in. The 'layman' or lessee was clearing \$40,000 in the season, of 4 months, after paying a royalty of 50% to the owner of the claim.

Another good example of the open-cut method was afforded by the operations on the Discovery claim of Cleary creek, in the Fairbanks district. This also is ground that has been partly worked in days gone-by. At the north or down-stream end of the claim 38,000 sq. ft. was being stripped of its overburden by means of two scrapers. The gin-pole had been erected at a point 250 ft. from the steam-engine that supplied the motive power. A scraper holding 19 cubic feet when full, or an average of half a cubic yard, was being pulled by a 5½-in. steel rope. Two men guided the movements of the scraper by holding wooden handles having sockets into which the iron levers fitted. They held the scraper to its work and when it was loaded, one of them rode on the load as far as the dump, to tend the dumping. Thus a thickness of 9 ft. for an area of 38,000 sq. ft. was being shifted onto last year's bedrock, that is, the ground that had been worked out during the previous season. In this work there were employed 6

men and 2 scrapers. The labor included 2 engineers, 1 foreman, 1 man trimming the bank, 2 working with the scraper. There were 12 men per 24 hours, with a foreman. The last mentioned and the engineers are paid \$7 and board; the others get \$6 and board, worth \$2.50 to \$3 per day.

The seepage is removed by a pulsometer. Removal of the nearly barren overburden proceeds until the 'pay' is reached. The foreman watches for this, by digging an occasional hole and panning the gravel. As soon as he gets a yield of 2 cents per pan, he stops the scraping. The average thickness removed by the scraper is 9 to 10 ft. Then the self-dumping bucket is brought into use. It required 6 weeks to make the cut that I saw—38,000 sq. ft. by 9 ft. deep. The work was delayed by the necessity for thawing a few patches of frozen ground. This was done with steam-points. The scraper cannot be employed in ground that is not wholly thawed.

Next comes the mining in the gold-bearing portion of the deposit. This could be watched at the south end of the claim, where the bedrock was 17 ft. below the surface. Twelve feet of overburden had been previously removed by scrapers, in the manner just outlined, and the lower 6 ft. of profitable ground was being attacked. A self-dumping bucket, of the kind already described, elevated the gravel to the dump-box at the head of the sluice-boxes. About 2 ft. of bedrock and 4 ft. of sediment constitutes the 'pay.' The bedrock is a soft decomposed yellowish mica schist traversed by occasional bands of hard quartzite, especially near the rim of the channel, where it makes a blocky irregular bottom. Usually, however, the bedrock is very soft and the transition into the detrital deposit is indicated more by the color than by any marked change of texture. The deposit is a confused mixture of slabs and sub-angular pebbles of schist, resembling a talus. The gold is in the fine sediment intermingled with the larger fragments. The average yield in the season of 1907 was \$5 per square foot of bedrock; thus 50,000 sq. ft. yielded \$258,000. Stated in another manner, the yield was \$20 per cubic yard for the total 20 ft. excavated. The best run in the Fairbanks district was made on this Discovery claim last summer: In 52 hours, 7 men with wheelbarrows extracted gravel that produced \$27,500. The period included 6½ days of 8 hours each; the cut had been stripped to the pay, and the work represented the removal of the bottom.

Operations proceed both by night and day. Three arc lights illuminate the workings by night. Thus in the season of 1908 no less than 70,000 sq. ft. of open-cut had been stripped at the time of my visit, on August 4. In the south cut there was no trouble with frost because the top 'muck' had been ground-sluiced; in the area covered by the north open-cut the grade was too flat for sluicing; hence the occasional patches of ice. Steam is made by burning wood at \$15 per cord delivered. The two 50-hp. boilers cost \$2200 apiece delivered. The two scraper-engines cost \$1500 each. Board for the men costs the operators \$3 per day, even when buying provisions on a good scale. The ground is being worked on a 50%

lay, for 3 years. John Webster is in charge, for D. G. Aitken, who is lessee from Frank G. Manley, noon hour, while the men are taking the mid-day meal, is devoted to this purpose by the chief operat-

Dump-Box and Sluices.

Hungarian Riffles.

After C. W. Purington.

ors. The owner of the claim is usually represented and this representative assists. The accompanying sketch illustrates the dump-box and the sluice-boxes. The top box is 4 ft. wide and 24 ft. long; the sluice-

Sketch of Gold-Saving Apparatus.

Sluice-Boxes, Showing Riffles. The Pan Holds the Gold From the Clean-Up.

While on Cleary creek, I was present at one of the 'clean-ups' on the Discovery claim. The gold is gathered for shipment every 4 days or 8 shifts. The boxes that follow are 16 in. wide. Of the latter there are 7. When operations start, only 4 sluice boxes are placed in position, but as additional space

is required for disposal of the tailing, more sluice-boxes are added from time to time. Each is 12 ft. long; therefore the total length of this gold-saving machine is 108 ft. When the bucket is discharged, the gravel falls upon the apron of the dump-box. This apron is inclined at 50° and is built of 3-in. poles nailed close together. The gold-bearing material slides into the dump-box and is washed down the sluices by the water issuing from a gate in a flume. The gold is arrested by riffles. These consist of poles, 3 in. diam. and 6 ft. long, 1 to $1\frac{1}{2}$ in. apart, nailed to two 14-in. cross-bars. They are laid lengthwise along the bottom of the sluice-boxes and are held in position by a 1-in. board on each side. The poles become worn on top and are replaced at alternate clean-ups, that is, after an interval of 8 days. When preparing to clean-up, most of the water is shut off. The gold can be seen readily, especially at the upper end. Picks are used to pry the side boards and loosen the riffle-frames. They are lifted to one side, being usually laid on the edge of the trestle that carries the sluice-boxes. A pick is driven into the apron so as to hold the first four riffle-frames, which are thus put out of the way. First, however, these and the other riffles are washed in the small stream of water still running down the sluices. Then the compact sediment lying on the bottom of the dump-box and on the first four sluice-boxes is shoveled until it is loose, preparatory to being put into iron buckets, which are carried to the head of the dump-box and there emptied so as to make a heap aggregating a little more than half a cubic yard. Then the washing begins. Water is turned on—about half a sluice-head of about 50 cu. ft. per minute. A wooden bar, 3 in. deep, is placed across the third sluice-box so as to check the descent of the tailing. One man stands at the head of the dump-box and shovels the golden sediment as the water runs past and at the same time the four other men check the flow with shovels and paddles so as to work it up toward the head, all the time separating the light and valueless sand from the heavy rich particles of gold. This concentrating process proceeds until complete. The water is turned off and the gold is seen lying on the bottom of the sluice-boxes in glorious heaps. Then whisk-brooms are employed to wash the gold to the head of the dump-box, the little water still running sufficing to remove the black sand and other small heavy impurities. The gold is shoveled into a pan. It looked like a heap of saw-dust or bran. On lifting the riffle-frames the bottom looked like a golden mosaic. Several nuggets—the largest $1\frac{1}{2}$ oz.—were found fully 30 ft. from the head of the dump-box. It is supposed that nuggets will roll down the pole-riffles, therefore a series of block-riffles, followed by Hungarian riffles, is placed below the others. To anyone accustomed to stamp-mills, the handling of the gold looked rather careless and the chance for catching fine gold seemed slight. The operation ended with a pan full of gold and a bucket full of a rich sandy concentrate. Both were re-washed in a separate sluice-box, 10 in. wide and 12 ft. long, using a whisk-broom to move the gold from side to side in a current of clean water.

Two bar-riffles served to arrest any that might otherwise escape. The cleaned gold is worth \$16.90 per oz. Impurities consist of rounded crystals of garnet and specks of both hematite and magnetite. This clean-up yielded \$14,000. Two men spend the larger part of an afternoon in eliminating impurities that could be slagged in a crucible within a few minutes. The explanation is that the operators dislike to put themselves in the power of the bank to which they sell the gold; if they clean the gold themselves, they know its true weight, and they avoid extra charges for refining.

Another example of the open-cut method was observed at No. $3\frac{1}{2}$ Above Discovery on Ophir creek, on the Seward Peninsula. The creek itself had been diverted. The ground is in a naturally thawed condition. Under the overburden of sand, the gravel is 4 ft. thick and is first excavated; then a second slice removes the bedrock to an additional depth of 4 ft. The bedrock is shaley limestone, with an irregular surface favorable to the concentration of gold. The ground is broken with the pick and the material thus released is shoveled into buckets, hauled and hoisted by derrick. The few large (more than 12 in.) stones or boulders are stacked in the centre of the excavation. A steam-derrick and 8 buckets are in use. There is a pair of men to each bucket. When it is full, the small cable from the derrick pulls the bucket along skids to a point immediately under the end of the boom, whence it is hoisted to the dump-box. The arrangement is closely similar to that described by Mr. Purington, who visited this locality four years ago. I have borrowed the sketch appearing in his account,* which is excellent. The buckets are made from drums that formerly contained oil (110 gal.); these drums have been cut down 8 in., and from the original hoop a bail has been made; this is attached so far below the centre as to cause the bucket to tip easily. Each bucket holds 11 cu. ft., being 2 ft. 8 in. high and 2 ft. 5 in. diam. One of these is discharged at the dump-box each minute. This equals 300 cubic yards per 24 hours, working a total of 42 men in two shifts. One man attends to the guy-rope and pulls the lever that upsets the bucket at the upper terminal; another attaches the hook in the mine. Drainage is effected by a hydraulic lift, by a China pump, and by a centrifugal pump, the three machines constituting a curious medley of mechanical contrivances. The man at the dump-box was not forking out any boulders—a sign of small gravel and plenty of water. The sluice-boxes are 26 in. wide. The dump-box has no apron. The yield is estimated at \$3 to \$4 per cubic yard. But even this return does not mean a fortune, for the royalty to the owner is 50% of the gross, and the cost is \$1 to \$1.20 per cubic yard. The profit is only 50 to 75 cents per yard during a season of 4 months. This is a good example of the mining operations that enrich idle owners who allow adventurous lay-men to assume the risk of operation. The result is to work the ground rapidly and extrava-

*'Gravel and Placer Mining in Alaska.' By C. W. Purington. U. S. G. S. Bulletin 263, p. 70.

gantly, leaving piles of tailing that will be worked again a year or two hence.

As claims were consolidated and capital was placed at the disposal of operators, the tendency was to enlarge the plan of operations. Ditches were built and a plentiful supply of water was brought into service. This rendered possible the employment of the hydraulic elevator, a machine consisting of an iron pipe, placed at a steep angle, so that the gravel is propelled to a higher level by means of a jet of water under heavy pressure. The material to be elevated

ground-slucing, yet not deep enough for drift-mining, where water was not available for hydraulic elevating, and where the ground was thawed, the dredge was employed to dig the alluvium. Thus another chapter was added to the development of mining in the North.

Finally, where the gravel lay on a bedrock unsuitable for dredging, especially in old creek diggings, where virgin ground, tailing heaps, old timbers, and other varying conditions were unfavorable to the methods already described, a combination was

is washed into the pit or receptacle at the foot of the elevator by means of a monitor or nozzle, emitting a powerful stream of water at high velocity.

The direct application of hydraulic mining was not possible in the creeks because of the lack of grade. Hydraulic mining is only practicable where the bedrock is steep and there is plenty of room for the discharge of the tailing; therefore it is confined to benches on hillsides or to the banks of creeks so situated as to give ample grade.

Where the gravel deposit was too shallow for

effected between dredging and hydraulic mining, and thus the mechanical elevator came into existence.

It is the story of the empirical development of mining methods and the imperial conquest of man over a wide domain of gold-bearing territory. Many contributed to the invention of new devices and even the most inventive gained from the stimulus of comradeship. The haste to become rich impelled most of the operators, but the ambition to do a thing well was a motive power to others. Nor is the evolution complete. It is still in progress.

COSTS OF LAKE SUPERIOR SMELTING.

Written for the MINING AND SCIENTIFIC PRESS
By L. S. AUSTIN.

Of the stock of this company, consisting of 48,000 shares, the Osceola owns 15,000, the Tamarack 25,000, and the Isle Royale 8000 shares.

These small works, treating something over 3000 tons monthly, have four furnaces in operation on concentrate from the Isle Royale, Osceola, Tamarack, and Ahmeek mines. The company formerly treated concentrate from the Atlantic, Wolverine, and Mohawk mines, as well as that from certain South-Range mines, notably the Champion, Baltic, and Tri-mountain. To the concentrate from the above-named mines there is added, to the extent of 50%, cathodes from the refinery of the Boston & Montana Co. at Great Falls, Montana. The product has been sold as Lake copper by the United Metals Selling Co. of New York, a company which has the sale of over 600 million pounds of copper annually out of the one billion produced in the United States. The product, arising from the mixture of the concentrate of any mine with these cathodes, is sold under the name of that particular mine, except that the Ahmeek goes into the molds of the Osceola brand.

The following table gives the output of the works for the years 1902 to 1906, inclusive:

Mine.	1902.	1903.	1904.	1905.	1906.
Tamarack	1,483,888	24,105,397	20,643,982	24,924,001	17,492,592
Osceola	18,351,531	28,707,914	30,455,359	32,853,213	
Ahmeek		416,167	2,548,106	5,180,293	
N E C & M A		8,231,731	None.	None.	
	1,483,888	42,456,928	57,999,797	57,927,466	55,526,088

Of the total copper produced under these names there was used of B. & M. cathodes the following quantities:

Mine.	1902.	1903.	1904.	1905.	1906.
Tamarack	845,953	11,408,778	8,853,278	12,466,285	9,650,594
Osceola		7,660,333	12,365,769	14,031,462	16,072,027
Ahmeek			135,150	1,211,435	2,508,838
N E C & M A			6,616,683	None.	None.
	845,953	19,069,111	27,970,880	27,709,182	28,231,459
	57%	45%	48%	48%	51%

Taking the year 1906, the monthly production of the mines concerned, not counting cathodes, was approximately:

	Lb.
Tamarack	800,000
Osceola	1,000,000
Isle Royale	200,000
Ahmeek	300,000
Monthly production	2,100,000

The concentrate, locally called 'mineral', from the Isle Royale was separately smelted and made into anodes, which were sent East to be treated at the Raritan works, Raritan, N. J. This copper was marketed as I. R. M. The Western, or B. & M., cathodes were treated at a charge of \$4 per ton, crediting the shippers with 99.8% of the weight as copper. Of the total of copper put into the reverberatory furnace, 12% goes into the slag produced in the melting, and this slag will contain 20% copper. The slag is after-

ward treated in a blast-furnace for the recovery of this copper, which is later again refined.

Referring particularly to the Osceola copper, this is made into wire-bars or cakes as desired, being refined until by test the copper has a conductivity of 98.5 to 100.6% when made into annealed wire-bars, or of 97.5 to 99% when made into ingots. The Western, or B. & M., anodes contain no more than 0.0024 to 0.0048% arsenic, and have a conductivity of 101.5 per cent.

Smelting Costs.—In the year ending April 30, 1906, there was smelted 41,176.88 tons of 'mineral', including 18.36 tons briquetted and smelted in the blast-furnace. This produced 12,515.34 tons of slag yielding 5374.81 tons of 'cupola blocks' of perhaps 95% Cu. These blocks were re-melted and refined in the reverberatories, so that the total material treated by the latter was 46,551.69 short tons, containing 55,526,088 lb. copper, or nearly 60% of the concentrate.

The summary of costs shows:

Items of expense.	For year.	Per ton of concentrate
Reverberatory—Operating	\$195,144.61	\$1.741
Miscellaneous	43,408.84	1.055
Construction	15,664.74	0.380
Blast-furnace—Operating	32,623.44	0.790
Miscellaneous	13,460.59	0.327
	\$300,302.21	\$7.293

The total blast-furnace expense per ton of slag is \$3.682. The most interesting cost-figures are those given in connection with the operation of the plant for April 1906. They are as follows: 'Mineral', including cathodes, smelted in reverberatories:

	Tons.
Tamarack	537.24
Osceola	1,109.43
Ahmeek	113.16
Isle Royale	172.94
Boston & Montana cathodes	1,101.88
	3,034.66
Cupola blocks	146.76
	3,181.42

Slag smelted in blast-furnaces:

	Tons.
From Tamarack concentrate	319.09
Osceola concentrate	343.09
Ahmeek concentrate	41.74

COSTS IN APRIL, 1906.

	For the month.	Per ton of 'mineral.'
Reverberatory expense—		
Operating:		
Labor	\$5,991.82	
Supplies, including fuel	4,728.51	
Power	329.69	
Repairs	1,598.71	
	\$12,648.73	\$4.168
Other expense:		
Labor	986.33	
Miscellaneous (distributed)	1,899.30	
	2,885.63	0.951
Construction	2,713.04	0.893
	18,247.40	6.012
Blast-furnace expense—		
Operating:		
Labor	495.05	
Supplies, including fuel	1,476.54	
Power	242.22	
	2,213.81	0.731
Other expense:		
Labor	612.55	
Miscellaneous (distributed)	474.82	
	1,087.37	0.358
	\$3,303.18	\$1.089

The miscellaneous expense, distributed, is as follows:

Labor (yard and office).....	\$1,119.85
Office supplies	98.02
General expense*	1,156.18
Heating	218.74
Teaming	644.72
Miscellaneous supplies	184.68
	\$3,342.26

*This includes cleaning yard, telegrams, express, telephone, electric lighting, proportion of general office expense, taxes, insurance, and share of engine expense.

Summary of costs for April 1906 shows reverberatory expense and construction, \$18,247.40; blast-furnace expense, \$3293.18; being a total of \$21,640.58, or \$7.101 per ton of concentrate. Miscellaneous expense has been distributed to the reverberatory and blast-furnace expense, and so does not appear in the summary. In the cupola or blast-furnace was smelted 776.47 tons of slag at an expense of \$3293.18, or \$4.241 per ton. Recapitulating, the furnace-expenses and construction show:

	Costs.	Per cent of total.
Reverberatory	\$15,534.36	72.08
Blast-furnace	3,303.18	15.33
Construction	2,713.04	12.59
		100.00

The smelting charges to cover expenses were:

Tamarack, 537.24 tons 'mineral' at.....	\$7.16	\$ 3,846.64
20(?) ingot barrels at.....	1.00	20.00
Osceola, 1109.43 tons 'mineral' at.....	8.75	9,707.51
Ahmeek, 113.16 tons 'mineral' at.....	8.75	990.15
Isle Royale, 172.94 tons 'mineral' at.....	7.16	1,238.25
24 ingot barrels at.....	1.00	24.00
L. & M. cathodes, 1101.88 barrels at.....	4.00	4,403.52
Total smelting charges for the month.....		\$20,230.07

The succeeding items of costs will be useful in enabling comparisons to be made:

Bituminous furnace coal, per ton unloaded.....	\$5.10
Bituminous boiler coal, per ton unloaded.....	3.15
Anthracite, per ton unloaded.....	5.65
Coke, per ton unloaded	6.90
Limestone, per ton unloaded	1.40
Iron ore, per ton unloaded	1.10
Poles, per cord delivered	3.42
Charcoal, per bushel	0.13
Labor, per day, refining	2.66
Surface labor, per day	2.11
Mechanics, per day	3.12
Team and driver, per day.....	2.66
Labor, handling copper, per day	2.48
Foreman, per day	6.00
Inspector, \$125 per month, per day	4.80
Weighers, \$70 per month, per day	2.70
Blast-furnace, inside labor, per day	2.11
Blast-furnace foreman, per day	5.00
Clerk, \$138.50 per month, per day	5.77
Shipper, \$75 per month, per day	2.90
Stenographer, \$80 per month, per day.....	3.08
Assayers, per day	3.30
Cooper, per day	2.50

The fuel used in the blast-furnace constitutes 19.4% of the slag, or 15.0% of the charge, being about in the proportion of one third anthracite to two thirds coke. Of the total charge of 1002.44 tons smelted, about 18% was limestone and 4.3 iron ore, which shows the infusible nature of the reverberatory slag. The item of 6 days for foreman would indicate that number of running days for the furnace, or an output of 166 tons of charge daily, using 15 men per shift. The fuel-cost was 98c. per ton of

charge, and labor was half that, or 49c. per ton. Iron, steel, and other supplies will be estimated at 3% of the total blast-furnace expense. In preparing for the run, \$137 was expended in getting the blast-furnace ready, while for delivering charge and fuel to the furnace, repairing tram-cars, and removing waste slag, the cost was \$527, or 26c. per ton. The operating costs for the blast-furnace seem excessive.

The coal used in the reverberatory furnace was 32% of the charge smelted; 10 poles, or two thirds of a cord, and 15 bushels of charcoal were used per charge, and each furnace would need 14 to 16 men per 24 hr. The miscellaneous supplies, such as slag, sand, lime, castings, iron and steel, tools, etc., amount to 8.5% of the total reverberatory expense, exclusive of new construction, that item being 12.6% of the total, as already specified.

The miscellaneous expense constituted 15% of the total charge against the plant, and such a proportionately large amount must be spent by each of the five smelting works now treating Lake copper. A plant for the treatment of the Lake 'mineral', both by electrolysis and by reverberatory smelting, would naturally be situated at Buffalo. Use could be made of water-freight to ship in the open season, and it would go by rail in winter. The lower-grade concentrate, containing about 20%, could be briquetted and smelted near the mines by a blast-furnace, and the copper shipped to Buffalo.

Dynamite of any given grade will develop differing degrees of explosive energy in accordance with the force of the original detonation communicated to it by the cap used. In other words a 5X cap will develop greater disruptive force in the powder than a 3X cap. The reason for this is primarily that the 'combustion' is more perfect, the amount of CO₂ produced being greater in proportion to the CO than when the detonation is weak. That means the development of a higher temperature in the gases of combustion, augmenting their expansive power. Moreover, the velocity of the detonating wave varies as the force of the impact occasioned by the explosion of the cap, which means that the entire charge is gasified more nearly instantaneously, thus avoiding loss of energy through expansion of the gases into cracks produced in the rocks as a result of the relatively slow combustion during the explosion of a charge under a weak detonating impulse.

Abolition of metal gauges is being urged in a vigorous campaign by the Association of American Steel Manufacturers. They hope to induce manufacturers and users of materials commonly described by a gauge-number hereafter to designate sheets, wire, rods, tubing, hoops, and the like by thicknesses in decimal parts of an inch instead of by gauge-number. This change is not intended to apply to finished articles, such as screws, nails, rivets, or to manufactured articles known to the trade by size numbers. The Westinghouse Electric & Mfg. Co. has been following this practice for five years, and with the adoption of decimal designations they were enabled to dispense with ten or more different gauge systems formerly used.

NEVADA STATUTE FOR PROTECTION OF INVESTORS.

Nevada has taken an important step toward the protection of investors by the enactment of the Kendall bill, which requires all mining companies to mail to stockholders, and to file in the office of the County Recorder, each June and November, a statement showing:

(a) The name of each mining claim and the total number of such claims or fractions thereof owned or leased, and the number thereof being worked or developed, also the county and mining district (if there be one) wherein said claims are located, and the nearest postoffice and the distance therefrom, as near as can be ascertained.

(b) The nature of the title thereof, or interest therein, whether leasehold or otherwise, also the date each claim or interest therein was purchased, leased, or otherwise acquired by such corporation.

(c) The character, value, and a general description of all buildings, works, machinery, and other improvements on each unpatented claim, and the character, value, and a general description of all buildings, works, machinery, and other improvements being actually used or operated by such corporation on its patented ground, taken as a whole.

(d) The total number of days labor employed and expended in actually developing the mineral resources of each unpatented mining claim, if any, and of the entire patented property, if any, during the six months next preceding, and the total sum of money, or other valuable consideration, given or paid out therefor.

(e) The total number of shares such corporation is by law authorized to issue and the different classes and par value thereof.

(f) The total number of shares of stock originally set aside by such corporation, if any, in its treasury or otherwise, to sell or otherwise dispose of for the purpose of working, developing, or otherwise improving any patented or unpatented mining claim, or claims, owned or leased or being worked or developed by such corporation, and the total amount of money realized from the sale of any portion thereof during the six months next preceding.

(g) The total number of shares of treasury stock sold, the price thereof per share, and the total sum of money or other consideration received therefor during the six months next preceding the date of filing of the statement herein required, and the number of shares of treasury stock remaining unsold at said time.

(h) The amount of money, if any, actually paid by such corporation to each of its officers, superintendents, or to other persons, as salary or compensation for services rendered such corporation, stating the nature of such services; also, the respective amounts, if any, expended for advertising and as commissions for sales of stock, during the six months next preceding the filing of said statement.

(i) The total amount of bullion tax paid during the six months next preceding.

It is further made unlawful for any corporation

officer, agent, or director to issue stock or to sell or offer for sale any certificate upon which is not stamped or printed in English letters or characters at least one half inch high, the words 'Treasury Stock', or 'Promotion Stock', as the case may be. Treasury stock is defined as "stocks or shares that have been or shall be specifically set aside to sell for money, or other valuable consideration, and the proceeds of which are to be used for the actual development of the mineral resources of any mining claim or for the purpose of making necessary improvements thereon," while "all other stock of such corporation is defined as promotion stock." Penalties of fine or imprisonment are provided for violation of the act, and resident agents are made responsible for the acts of foreign companies.

PERILS OF A PROFESSOR.

Our readers are aware that when any earthquake or other unexpected occurrence happens, in fact, anything that can be labeled a geological phenomenon, it is usual for the gentlemen of the daily press to seek an interview with scientific men qualified to express authoritative opinions. The scribes of the press call them 'savants', but they survive even that. Then they publish a distorted report of what has been said, and the compositor heightens the mystery of the performance by interpolating a few typographical errors. The result is impressive but unsatisfactory. Every time a seismic ruction happens the reporters in New York rush to Morningside Heights and interview our distinguished friend Mr. Kemp, the professor of geology in Columbia University. He is both good natured and brave, so he meets the bombardment of questions and does his best to illuminate a dark world. But the ingratitude of mankind is proverbial; therefore such epistles as the annexed:

January 12th, 1909.

Dr. James F. Kemp.

New York City, N. Y.

Dear Sir:—

I read your opinion on the Sicily earthquake in the Kansas City Star. That you are a natural born fool is not what I wish to say, but that your argument lacks common sense would come nearer to the point. You say the earth is contracting. Stop and think. What would contract a melted earth, heat or cold? How can the inside shrink faster than the outside? Which would cool off faster, the inside or the outside? Volcanoes have volcanic ash, showing that something has been burned up. How can combustibles pass through regions hotter than eternal torments to be burned up afterwards by volcanoes? What is the earth doing, cooling off or warming up? It is taught in the schools latitude about 42 was covered with fields of ice not many thousand years ago. You know that that ice is not there today. How can that ice disappear with the earth cooling? If you give it up, I would like to hear from you. If you are willing to learn, I am willing to teach.

Resp. yours.

(Signed) J. R. SNELLING,
Blanchard, Louisiana.

COMPANY REPORTS.

BROKEN HILL SOUTH SILVER MINING COMPANY.

The report of this company for the half-year ending December 31, 1908, shows 112,288 tons of ore raised, yielding 16.2% Pb, 5.6 oz. Ag, 12.1% Zn. Of this 16.9% came from the lowest, 970-ft., level, 50.5 from the 825, and 23.4 from the 725-ft. levels, respectively. Ore was milled at the rate of 4252 tons per week, as against 3031 for the previous half-year, and it is stated that the new mill has disappointed critics and vindicated the estimates of W. E. Wainwright, the manager. Mining costs for the period are given at 9s. 3.3d., compared with 13s. 4.7d. for the corresponding period of the preceding year. Milling costs were 14s. 2.8d. and 21s. 4.8d., while 5.2d. and 3.04d. was spent in developing during the periods compared. A portion of the tailing is being used for stope-filling, this accounting for 11.1d. of the mining cost already given. American zinc and lead producers will be interested in the estimated tonnage of accumulated tailing and slime. This shows: Old mill-tailing, 1,078,743 tons, carrying 6% Pb, 3.7 oz. Ag, 16.7% Zn; new mill-tailing, 33,039, with 4.3%, 3.4 oz., and 18.7%; and slime, 158,636, with 12, 6, and 16.3, respectively. No dividend was paid during the period covered by the report, but £20,000 was distributed in January. M. E. Greene, chairman of the board, makes the following statement regarding information given to stockholders: "Since the formation of the company it has been the practice to issue half-yearly accounts and reports, and to give the press weekly statements. The directors disclaim any desire to keep from the shareholders any information; in fact, they know of no company whose reports and accounts are more full and complete. If quarterly reports or any specific information are desired, the directors will cheerfully supply the same."

STRATTON'S INDEPENDENCE.

This famous mine, at Cripple Creek, Colorado, has seen its best days. According to the report for the year 1908 the output was 5778 tons having a gross value of \$163,179. This was mined by lessees, who paid a royalty of 36%. The total receipts from such royalties were \$41,492. In 1907 the gross output was \$602,464, the great falling off being due to the exhaustion of the known deposits of high-grade ore. A flat royalty of 20% is now exacted on all ore mined, and this new arrangement has proved satisfactory, encouraging tributers to mine the low-grade stuff. The new mill to treat the old dumps has been started. Phillip Argall is consulting engineer.

MYSORE.

From the report of the Mysore Gold Mining Co. for the year 1908 it is apparent that this great mine is doing well. The mine is in the Kolar district of India, the company is English, the management is in the experienced hands of John Taylor & Sons.

In 1898 the output was 206,170 tons, yielding 191,766 oz., or an average of 18 dwt. 14 gr. per ton. In addition, 184,643 tons of tailing were treated by cyanidation, the yield being 24,722 oz., or 2 dwt. 16 gr. per ton. Thus the total recovery was 216,488 oz. of bar gold worth £848,145. The expenditure was £351,902. After payment of royalty, the profit was £458,285. Thus the results were the best on record. The dividends for the year amount to £350,055. As compared with 1907 the tonnage of ore treated is greater by 11,332, and of tailing by 17,114; the gold won has increased by 7047 oz., equal to £28,031; the expenditure is £5694 less, and the profit is £29,229 more.

The mine has reached a depth of 3908 ft. below the surface. At 3845 ft. a cross-cut intersected the lode, and drifts proved it to be 3 ft. wide, averaging 1 oz. 14 dwt. per ton on one side and 2½ ft. averaging 1 oz. 3 dwt. on the other. The lode continues strong and rich at each succeeding level. On December 31, 1907, the reserves were computed at 904,139 tons; on December 31, 1908, the tonnage in reserve is estimated at 969,920, so that the exploratory work has added to the life of the mine in a most satisfactory manner. Arthur Gifford is the superintendent.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

ENTRY OF COAL LANDS—CRIMINAL CONSPIRACY.

The Statutes of the United States make criminal a conspiracy to obtain title to public coal lands with the purpose of defrauding the United States in any manner or for any purpose.

United States v. Keitel, 29 Sup. Ct., 123, Oct. '08.

ENTRY OF COAL LANDS—EXCESSIVE AMOUNT.

Persons entitled under the United States Statute to a preferential right of entry of coal lands are prohibited from making more than one entry by the same person and from entering such lands apparently for themselves, but in fact as agent for another who has already purchased the full quantity permitted by law.

United States v. Forrester, 29 Sup. Ct., 132, Oct. '08.

MINING PARTNERSHIP—LIABILITY OF RETIRING PARTNER.

A mining partnership, unlike an ordinary one, is not dissolved by the sale of the interest of one of the partners; but it does not follow, from the mere continuance of the partnership, that the partner selling his interest continues liable for all of the debts of the partnership subsequently incurred. Under certain circumstances he may continue liable for a subsequently incurred indebtedness of the firm. Thus, where the partnership was indebted to laborers for work done while the selling partner was still a member of the firm, and the laborers continue their work upon the property without notice of the sale of the partner's interest, the retiring partner will continue to be liable. The rule is that the liability of a general partner for the acts of his co-partners continues, after dissolution of the partnership, in favor of persons who have had dealings with and given credit to the partnership until they receive notice of the dissolution. But a retiring partner is not liable for the wages of miners after the sale of his interest where they have notice of such sale; neither is he liable for the wages of miners subsequently employed, and who had no knowledge of his connection with the partnership.

Kelley v. McNamee, 164 Fed. 369, Oct., '08.

MINING CLAIM OWNED BY CORPORATION—ASSESSMENT WORK BY STOCKHOLDERS.

Stockholders of a corporation have such a beneficial interest in the corporate property that mining work done by them on unpatented claims of the corporation must be counted as representative work; and if the work so done by them is sufficient in amount and performed within the time, it will prevent a forfeiture of the claim.

Wallis v. Davies, 164 Fed. 397, Oct., '08.

INSPECTION OF MINES—DUTY OF OWNER.

The extent of the responsibility of a mine owner in regard to the inspection of mines for the benefit of licensees, depends upon the nature of the premises and the character of the work required. The frequency with which inspection should be made cannot be determined as a matter of law, but is a question of fact to be determined by the jury on the trial of the case.

Tennessee Coal, Iron & Railroad Co. v. Burgess, (Ala.) 47 South. 1029, Dec., '08.

GAS LEASE—METHOD OF SURRENDER.

The surrender of an unrecorded mining lease need not be in writing. Any notice is sufficient that definitely informs the lessor that the lease has been surrendered; but the original lease should be re-delivered to the lessor or destroyed. A recorded mining lease can only be surrendered by an entry duly made and acknowledged on the margin of the record, or by an instrument signed and acknowledged by the lessee.

Ward v. Triple State Natural Gas & Oil Co., (Ky.) 115 Southwest. 819, Jan., '09.

Single Horizontal Piston-Pressure Pump.

The accompanying engraving shows the salient features of a pump just put on the market to meet the demand for a machine of moderate cost and simple construction, which will stand the wear and tear of rough usage, and which at the same time can be operated without skilled attention. It is a strong plain pump, designed particularly to overcome the objectionable features common to most pumps of its class. It is thoroughly adapted for rough mining service, for contractors' use, for boiler-feeding, or for any pressure-work up to 200 lb. per square inch working water-pressure.

The valve gear is wholly enclosed, and there are no exposed working-parts that can be tampered with, or become broken by accident. The pump can be put into unskilled hands, will stand abuse and neglect, and keep on doing its work without giving trouble. Suction openings are cast on both sides of the pump-cylinder, and the discharge-outlet can be faced in four different directions for convenience in making pipe-connections. The steam and water-cylinders can be turned end for end on the centre-piece connection so as to bring the hand-holes and pipe-connections into the

most accessible position when the pump is used in cramped situations. All of the water-valves and valve-seats are securely locked into place, so that they cannot get adrift under any conditions, and at the same time they can be quickly removed for inspection or replacement. Great care has been taken to make this pump applicable to the varied conditions demanded by miners and contractors. These pumps are denominated "Type M." They are in a great variety of sizes, and prompt shipment can be made by the manufacturers, the Blake & Knowles Steam Pump Works of New York and Boston.

Catalogues Received.

THE CYCLOPE DRILL CO., Orrville, Ohio, has just issued a folder illustrating a number of standard outfits for well machines, prospecting, and the like.

THE W. S. ROCKWELL CO., New York, is distributing a small pamphlet which comprehensively describes the Rock well rotary annealing and hardening furnace.

THE WILLIAMS GAUGE CO., Pittsburg, Pa., has just issued a 16 page booklet on the economic operation of steam power plants, which it will send to anyone interested.

THE STROMBERG CARLSON TELEPHONE MFG. CO., Rochester, N. Y., has just issued two small pamphlets, No. 13 and 14, the former on magneto telephones for train dispatching and the latter on its compact type magneto wall telephones.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

THE GAS ENGINE. By Cecil P. Poole. 8vo., pp. 97, Ill., Index. New York. Hill Publishing Co. 1909. Price \$1.

As a ready assistant, quite different in character from the more elaborate treatise of Forrest R. Jones, is this little volume, which undertakes to cover much the same ground in a condensed form and in a more empirical manner. It contains a most useful chapter on pressure, temperature, and output calculations, with formulae, supplemented by elaborate tables of expansion-ratios, piston-displacement, values of certain constants, and so forth. The work has its own special importance in the field indicated.

CONTRIBUTIONS TO THE TERTIARY PALEONTOLOGY OF THE PACIFIC COAST. I. THE MIOCENE OF ASTORIA AND COOS BAY, OREGON. By W. H. Dall, U. S. Geol. Sur., Prof. Pap. 59. 4to., pp. 279, 22 fig.

BIBLIOGRAPHY OF NORTH AMERICAN GEOLOGY for 1906 and 1907, being Bulletin No. 372 of the U. S. G. S. By F. B. Weeks and J. M. Nickles. Obtainable free of charge from the Survey office, Washington, D. C.

PROCEEDINGS OF THE AMERICAN MINING CONGRESS. Eleventh annual session, Pittsburg, Pa., Dec. 2-5, 1908. 8vo. 122 and 268 pages.

Commercial Paragraphs.

THE DENVER FIRE CLAY CO., Denver, announces that it is agent for the American Smelting & Refining Co.'s litharge and test lead.

F. W. BOSTWICK has recently been appointed general western agent for the Norwalk Iron Works Co., and has opened an office at 611 Ideal Bldg., Denver, Colorado.

HERMAN NIETER, for the last two years Eastern sales agent for the CANTON BOILER & ENGINEERING CO., of Canton, Ohio, has been appointed sales manager for that company and will make his headquarters at Canton, Ohio.

THE HAMMOND IRON WORKS, Warren, Pa., has recently received an order for tanks and zinc-boxes for the Aguacate Mining Co., of Costa Rica. The order includes the erection, and 24,000 ft. of 5-in. riveted steel pipe. The same firm will soon ship an order of cyanide tanks to the Carmen-Guanajuato Mining Co., of Guanajuato, Mexico.

CHALMERS & WILLIAMS, Chicago, advise that they have recently received orders from the Aguacate Mines, Costa Rica, for a 100-stamp mill, including Kennedy crushers, Burt cyanide filters, and Chalmers & Williams tube-mills; and from the Lluvia de Oro Gold Mining Co., Lluvia de Oro, Mexico, for two 48 in. by 20 ft. Burt cyanide filters.

THE WOOD DRILL WORKS of Paterson, N. J., has recently shipped complete drilling outfits to the following schools for use in demonstrative work and instruction, and is issuing an enlarged sectional cut of the machine for use in class work: University of Missouri, University of Colorado, University of Michigan, State University of Kentucky, and University of Washington.

THE GENERAL ENGINEERING CO., of Salt Lake City, Utah, has received orders from both the British Mexican Development Co., of Mexico City, Mexico, and from the Transvaal University College of Johannesburg, South Africa, for one of their miniature testing plants. This same company has also secured a contract for a 100-ton concentrating plant for the Bingham-New Haven Gold & Copper Mining Co., Bingham Canyon, Utah.

THE ALLIS-CHALMERS CO., Milwaukee, in its Bulletin No. 1134 describes its line of hydraulic classifiers.

EDITORIAL.

A SIERRA MADRE club is forming at Los Angeles to bring together especially the mining and oil operators. It starts out auspiciously with Mr. Seeley W. Mudd as president.

THE MINING world has completely overlooked its interest in the tariff on jute and cotton bagging. The duty as fixed by the Payne bill will maintain the price 40 per cent higher than if these materials were placed on the free list. The industry is in the hands of a trust, only three factories in the United States making such fabric.

ELIHU ROOT has done many things for which his countrymen may be grateful. He has added to the obligation by suggesting that the fund given in his honor to Hamilton College by Mr. Andrew Carnegie be not spent on a building. Instead it is to be invested by the trustees and held, the income to be devoted to the salaries of instructors.

SEA-BORNE MAILS to the North are to be resumed May 10, when the first steamer sails from Seattle bound for Nome. The open season this year has come unusually early. We hope the ice may break up sufficiently for the *Corwin* to make a swift and uninterrupted voyage, since the coming of the ships is the best sign of spring to our friends on Seward Peninsula.

OKLAHOMA mining claims are again attracting attention, and the Land Office has been re-investigating the matter. In the Wichita mountains there are many dikes and a few veins. Some of the latter carry small amounts of galena and copper. These, in combination with dishonest assayers and inexperienced prospectors, have led to many fair dreams, which have so far failed of embodiment.

STEWART, of Nevada, was one of the uncorrupted and incorruptible members of the Senate. At this time it is proper to recall the leading part he took in exposing the nefarious jobbery of McKenzie and Noyes at Nome in 1900. Stewart's clear exposure of that amazing affair was so thorough that, by request, it was expunged from the Congressional Record; but it fulfilled its purpose by putting an end to the anarchy in Alaska.

CONGRESS has before it a proposition to suspend assessment work on mining claims for the year 1909. This is unnecessary and unwise. The essence of the possessory title is that the holder shall show good faith by continuous working. The legal requirement of work, to the value of \$100 per year on each claim, is modest. Only by holding to that can development of our territory be secured. There is no

benefit to the country from allowing areas of mineral ground to be held for speculation, and to open the way for this would be only justifiable because of a great national emergency. No such need now exists, and the proposed action is vicious.

MEXICO has discovered a new method of shielding home industry from foreign competition. By control of the railway systems through the recent merger, the Government has found it possible to apply discriminating freight rates, having the same effect as a protective tariff. By a recent executive order coal and coke entering the Republic through Laredo, Tampico, or Vera Cruz will be charged an extra peso per ton. The development of infant industry has ever awakened the demand for political nursing.

KENTUCKY is not entirely devoted to the production of tobacco, bourbon, and feuds, but has an important and imperfectly appreciated mineral production. With its large reserves of high-grade coal, its oil, fluorspar, and iron ores, it has the basis for an even larger mining industry. As the best means of developing this the State maintains an active and efficient geological survey, which has just issued a new map of the State. Mr. C. J. Norwood, Director of the Survey, is to be congratulated on its appearance.

THE ARREST of two men in Pittsburg, charged with checking baggage containing explosives, calls to mind the new law which prohibits taking explosives into any passenger or baggage car. They can now only be shipped by freight, and when prepared in accordance with the rules of the Interstate Commerce Commission. Full information must be given the railway or steamship line, and any violation of the law is punishable by fine or imprisonment. Hereafter new means must be found to balance accounts with baggage smashers.

GEOLOGICAL and topographical surveys of China were suggested last week by Mr. F. L. Cole, as a suitable gift to our neighbor from some of our benevolently inclined rich. In these days when even lakes are passed about as presents, the plan has an air of feasibility. Indeed, an excellent survey has already been made of a portion of the Empire by Mr. Bailey Willis, under the auspices of the Carnegie Institution, and Mr. T. C. Chamberlin is even now in China on behalf of the University of Chicago. These, however, are scientific surveys; the gift of the scholars of the New World to that civilization of the Old which even more than our own dignifies the status of scholar. Such fundamental studies are of international importance. They have no direct bearing on exploitation, and in financing and supporting them America is but paying back a debt we ourselves owe to Europe. To organize a systematic topographical and geological survey of a foreign country is, however, an entirely different matter, and might well be regarded as an impertinence. We may claim the privilege of studying the world-wide problems of science, just as we concede it to all, but definite plans looking to the development of a neighbor's property can only be made on invitation. We understand that Mr. R. H.

Chapman of the United States Geological Survey has just been loaned to Canada to assist in the organization of topographical work, and the vigorous and far-seeing secretary of the Smithsonian Institution, Mr. C. D. Walcott, has recently recommended that as soon as funds are available, systematic scientific exploration of parts of South America be undertaken. Both of these projects appeal to us, and we wish them prompt fulfilment. We would like to see a complete survey of China, but, desirable as it is, the Chinese must themselves undertake it, with such help from others as they may invite. In the meantime there is abundant opportunity for our millionaires to assist through scientific exploration in bringing America into contact with foreign countries on a plane above that of trade and dollars.

FLUORSPAR under the new tariff is to be given protection to the extent of \$1.50 per ton. This will be sufficient to confine importations to seaboard cities. At present English spar comes as far west as Pittsburg, when the market is divided with the mines of Illinois and Kentucky. West of Pittsburg there is no foreign competition. Colorado has its own supply, but such spar as is marketed elsewhere comes mainly from the Mississippi Valley. At present relatively little spar is sold, cheaper but less efficient fluxes being used. A large market is, however, possible in connection with the development of open-hearth steel-making. For this purpose an average of 5 pounds of spar per ton of steel is needed. While higher grades are preferred, and so far have mainly been supplied, material carrying 90 per cent of calcium fluoride can be used. With the reserves of bessemer ore being rapidly depleted, open-hearth steel-making is bound to increase, and with that a wider and more active market for fluorspar. A protective tariff will be particularly stimulating, and would not be an undue burden on the steel-industry. The building of the great open-hearth steel-plant at Gary will furnish an especially good market for the Illinois mines, and the whole will accentuate in some degree the tendency for the centre of steel manufacture to move westward.

Federal Coal Lands.

An important step in the revision of the Federal mining laws was taken by the last Congress in providing for the separation of surface from mineral rights in the case of certain coal lands. Heretofore land in the coalfields has been classified as either mineral or non-mineral, and patents have carried full title. The classification was for many years done by the Land Office, and unless there was an actual showing of coal or a very clear proof of its presence at shallow depth, the land was generally classified as 'non-mineral', and was sold at agricultural prices. Lands classified as 'coal-bearing' were sold at ten and twenty dollars per acre, depending on the distance from a railway line. They were often taken up at the lower rate, in advance of railway building, by people presumably having inside information.

About three years ago the classification of the public lands was undertaken by the Geological Survey.

as specifically provided by law. "New surveys were made, and with the improved understanding of the stratigraphy, much land was found to be properly coal-bearing which had been taken up in good faith by agricultural claimants. In view of the fact that the prices at which coal land had been previously sold were merely minimum prices set by the law, a new schedule was prepared, under which some of the land was priced as high as \$100 per acre. In situations the new price was far beyond the value of the homesteaders, whose claims were held up pending the adjustment of the matter. Congress came to the rescue by providing that such claimants might elect either to proceed to title, taking their chances on proving the non-mineral character of the ground, or they might receive title to the surface upon relinquishment of coal rights. It is provided, in event of the latter election being made, that the coal deposits under these lands shall then be subject to disposal by the United States, but that "no person shall enter upon said lands to prospect for, or to mine or remove coal therefrom, without previous consent of the owner under such patent, except upon condition as to security for and payment of all damages to such owner caused thereby." It is further provided that the owner under the patent may mine coal for his domestic use, prior to the disposal of the coal rights by the United States. The new law, by providing for separate ownership of surface and mineral rights in the same ground, opens the way to the adjustment of many difficulties. While the principle is perhaps capable of wider application as regards the public lands, it is peculiarly adapted to coal lands. It is no experiment. The great bulk of the coal mined in the United States has for many years come from land in which title to the surface and to the coal vests in different parties. This has usually resulted from sale or lease of coal rights by fee-owners who originally acquired possession under agricultural title. We have sold the surface and, usually, thrown in the minerals. The new plan gives each owner the particular thing he pays for, and this works equal justice. It is a welcome move in the direction of a more scientific utilization of our resources.

William Morris Stewart.

Another Argonaut has gone. In all that company of daring spirits that brought a vitality and power to California enriching the State more than its Golden Fleece enriched the world, none has left a more enduring mark upon his country than William Morris Stewart, the father of the Federal Mining Law. He is responsible for a departure from the time-worn customs of tenure in real estate that was revolutionary in principle and practice, and he saved the mines of the public domain from a perpetual burden that would have weakened the West and have delayed the development of our political solidarity for generations.

Stewart was born near Lyons, New York, in 1827. Attracted by tales of opportunity in the new El Dorado, he left his studies in Yale College, arriving at San Francisco in May 1850. Those were the days

when a little training counted heavily. He studied law; became district attorney in 1852; and two years later was attorney general for the State. In 1860 he moved to Virginia City, Nevada, and in 1863, when barely qualified by age, he was on the floor of the National Senate. There his personality was soon strongly felt. It was no weakling who could cross swords in financial debate with so redoubtable a champion as John Sherman, and end by substituting for his cherished measure, aimed at providing revenue, a bill shorn of every feature which had led the Ohio Senator to propose the enactment of a general mining law. After the distinguished services which Stewart rendered to his country it is painful to think of the financial struggle that embittered his declining years. By a man's own skill in the warfare of life must he rise or fall. A nation seldom rewards the veterans of great battles won in legislative halls. Save for Stewart the mines of the West would have been handicapped by a royalty sufficient to extinguish the margin of profit by virtue of which a great proportion of them exist.

The first Federal mining statute was passed in 1866. The country was staggering under a stupendous debt from which the wisest could offer no certain means of escape. Commerce was conducted with depreciated currency, shifting in value from day to day; repudiation was freely talked; and credit, both national and private, was strained to its 'elastic limit'. The foremost concern was to raise revenue to meet current expenses and accruing interest on Government bonds. In such extremities it requires the faith and vision of a seer to rely on the expansion of industry to afford relief through expanding income. The readiest available resource is to increase taxes, and to levy new taxes upon existing enterprises. The most impressive contributor to wealth at that period was the golden West. The opulence of California, compared with other portions of the country, loomed cyclopean. Riches from the Western mines appeared to come easily; the average of prosperity and failure, the sheer cost of success, were overlooked. Hence the proposal to sell the mines and saddle the output with a royalty met with instant approval. It was shifting the burden of responsibility, which is a comfortable procedure for the one whose shoulders become disburdened. Many conditions favored such a measure. The status of the mines had not yet been accurately determined. They were administered by local regulations, varying from camp to camp, but recognizing the right of location and of following the vein in depth within the longitudinal limits of the claim. Furthermore, the ownership by the United States of mineral rights in public lands, acquired by cession from Mexico, had but recently been affirmed by Mr. Justice Field in the famous case of *Moore v. Smaw*. Prior to 1861 California asserted that the minerals obtained by treaty with Mexico were held in trust by the nation for the benefit of the State as soon as admitted to the Union. If such a precedent had been established, mining throughout the Southwest would have been involved in confusion.

Bills were simultaneously introduced into the Sen

ate and House by Sherman and Julian respectively. These were drastic fiscal measures, involving sale of the mineral lands subject to a five per cent royalty. The tactical skill of Stewart was shown in the first instance by his daring substitution of a radically different act for the Sherman bill in the Committee on Mines. Of this committee Stewart was a member. He was ably seconded in his efforts by Conness of California. The consent of the committee was secured merely in the expectation of giving the proposal an advanced affirmative standing. That it would be passed was not contemplated even by Stewart and Conness, but when the bill was reported, on June 18, 1866, they assumed an aggressive attitude, which was rendered the more effective because of the almost total ignorance of mining on the part of the other Senators. Although opposed by Williams of Oregon, and by many others, Sherman, Buckalew, and Hendricks betrayed appreciation of some of the merits of the bill. Encouraged by this small success, Stewart called the measure up ten days later, and after debate, which displayed laughable lack of geologic knowledge, it was passed. In the House, however, Julian, with the usual persistence of 'The Gentleman from Indiana', and enamored of the bill which he had drawn, acrimoniously fought the Senate measure. His first move was to seize upon it for the Committee on Public Lands, of which he was a member. There he insisted on reporting his own bill first. Meanwhile Stewart, by a canvass of the House, assured himself of a favorable disposition toward the Senate bill. Accordingly when a bill from the House relating to ditches for mining operations came into the Senate, the Stewart bill, No. 257, was attached as a 'rider'. It had then to be referred back to the House, and went on the Speaker's table. Julian made strenuous exertions to obtain the necessary majority to refer it again to committee, but failed. Thus the Stewart bill became the first Federal mining law, under the anomalous title of "An Act granting the right of way to ditch and canal owners through the public lands, and for other purposes."

The fact that Stewart was only crystallizing local usages, the operation of which he commended with more skill than their success would warrant, disarmed those who might otherwise have taken alarm at the radical concession to invade adjacent property by following the vein on its dips, angles, and spurs. The revolutionary principle of an extra-lateral right was granted with no apparent understanding of its far-reaching significance. It was done as if it were a piece of routine business—the granting of a pension, or the confirmation of a Presidential appointment. With such cool indifference was the traditional right of man in real property brushed aside by the efforts of a clever debater, fortified with a little special knowledge upon a subject which was mystery to his colleagues.

The law as passed soon displayed grave defects. No limits were set to the width of a claim, though its length was established at 200 feet, which in itself indicates the richness of the deposits worked and sought in those days when the West was young. The width of the claim, and many other matters,

were left open to regulation by local mining districts. Conflicts arose over this, and over the discovery of other veins within the area granted. In 1870 Stewart proposed a revision, and the bill passed the Senate but was laid over by the House. Two years later the same bill was introduced into the House by Aaron A. Sargent of Nevada City, California, and was enacted into law. It revealed the ripened thought from longer experience of mining. The need of absolute ownership of the surface had been learned. The claim was fixed at a maximum of 1500 by 600 feet; the right to all lodes or veins apexing within the claim was granted to the locator; the Act of 1866 enabled a locator to obtain a patent to a 'mine', that of 1872 provided for patent to land; under the earlier law lode-claims were limited to those bearing gold, silver, cinnabar, and copper, the later law conceded those and 'other valuable deposits'. After an experience of six years with a mining law at variance with those of every other country on the globe, Stewart was able to defend his measure and secure confirmation of its principles by an Act merely perfecting the details. The wisdom of departing from ancient custom has been denied by able critics, while certain merits of the system have found encomiasts. It was probably a blunder, but it was determined by the exigencies of the moment. Except for the clever substitution of his bill for Sherman's, the mineral industry would have been permanently oppressed by royalties that would have impeded the development of our greatest existing copper mines, that would have made gold mining in California a mere reminiscence, that would, in short, have stunted the industrial growth of the Nation. To have abruptly altered the miners' regulations would have weaned away that adherence of the other Western members in Congress without which no mining law other than a fiscal measure could have hoped for passage in the face of a general desire to exploit the mines as a means of paying the National debt. He did the best he could, and few men could have done as well. The minerals of the West were the basis of pioneer enterprise; the mines paid for blazing the trails across the continent. To have restrained this development by odious taxation would have set back the expansion of an empire. That the shackles were not fastened upon the miner is cause to honor the name of William Morris Stewart.

COBALT ORES are being smelted at Denver at the rate of more than 1000 tons per month. So large a movement of ore away from its final market is unusual. The reason lies mainly in the falling grade of Cripple Creek ores, which sends them to the mill rather than to the smelter. The resulting shortage in silica is felt severely at the Globe plant, and it is said that enthusiasm over the arrival there of a earload of silicious ore amounts almost to a celebration. Interesting as this ore-movement is in showing the interdependence of even the international mining camps, there is none the less a deplorable economic waste involved in shipping tons of silica some thousands of miles west, in order that ounces of silver and pounds of nickel shall later go east.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. H. WEED is at Ray, Arizona.

W. F. FERRIER is in San Francisco.

A. E. DRUCKER is in the Kolar goldfield.

M. L. REQUA has returned from New York.

POPE YEATMAN is here, on his way to Mexico.

W. L. POWBON is visiting mines at Quartzburg, Idaho.

DAVID McCLURE has started on a holiday trip to Europe.

RICHARD A. PARKER has returned to Denver from Arizona.

DAVID G. PUTNAM, of Los Angeles, was in San Francisco.

ALAN J. FAIRBAIRN has returned to Denver from Scotland.

C. COLOCK JONES is at Goldfield, Nev., on professional business.

P. M. PAINE, of the U. S. Land Office, has returned from Oklahoma.

FRANK J. DAVEY, formerly of Baker City, Oregon, is now at Spokane.

C. W. WRIGHT was married to Miss HELEN BREE DUNSTAN at New York, April 22.

R. GILMAN BROWN has gone to West Africa. He will return to London in May.

J. L. PEIERCE, who has been in western Arizona, will return to Nome in June.

ARTHUR S. EAKLE has returned from Germany, and is at Washington Grove, Maryland.

BENJAMIN B. LAWRENCE has been elected the first 'alumnus trustee' of Columbia University.

DAVID GOODALE has taken a position with the Trinity Gold M. & R. Co., Carrville, California.

ALLEN C. REDDING has gone to San Luis Obispo county, California, on professional business.

E. J. SCHRADER, of the San Miguel G. M. Co., Sonora, has gone to St. Paul, Minnesota, for a vacation.

PERCY E. BARBOUR has become manager of the Promontorio mines, at Minas Nuevas, Sonora, Mexico.

NORVAL J. WELSH, manager of the Santa Brígida mines, Chihuahua, Mexico, is at the Engineers' Club, New York.

DRUMMOND MACGAVIN is on the staff of W. F. FERRIER, geologist to the U. S. S. R. & M. Co., at Mammoth, California.

H. HUGHES, late of the Transvaal Gold Mine Estates, Ltd., is manager for the Ventanas Mining & Exploration Co. at Durango, Mexico.

THEODORE GROSS is resident manager in the United States and Mexico for the London Venture Corporation. His address is 165 Broadway, New York.

R. H. CHAPMAN is at Ottawa, Canada, organizing topographic work for the Canadian Geological Survey. He is expected later on the Pacific Coast.

W. R. WARDER, formerly of the De La Mar Gold Mines Co., in Nevada, has been appointed general manager for the Golden Star Mines Co., at Kofa, Arizona.

A. F. McCORMICK and P. K. HORNER, formerly at the Step-toe smelter, Ely, Nevada, have gone to Katanga, Congo Free State, Africa, to take positions with W. G. PERKINS, who has been appointed metallurgist for the Tanganyika Concessions, Limited.

THE PACIFIC COAST SECTION of the Mining and Metallurgical Society of America met at the St. Francis Hotel on the evening of April 27. The following members and guests were present: S. B. Christy, C. W. Merrill, M. L. Requa, E. A. Hersam, W. H. Shockley, T. A. Rickard, A. C. Lawson, F. W. Bradley, H. W. Turner, George B. Starr, H. F. Bain, Edmund Juessen, Whitman Symmes, Joseph Shockley, C. W. Purington, and J. F. Newsom. The report of Mr. Requa as delegate to the New York meeting of the Society was received and discussed. Mr. Rickard resigned as local secretary and Mr. Bain was elected in his stead.

Obituary.

PERSIFOR FRAZER, who died in Philadelphia, April 7, was a notable scientist of a type rarely found in this country. A man of wealth, he devoted his talent and his time to high endeavor, working in that spirit of intellectual integrity which is more easily possible to one absolved from the need of earning money if he happen to possess a fondness for work for its own sake without using it to display his vanity. He rose far above the level of a dilettante. He was a man of many parts, and gifted with a diplomatic skill that enabled him to play an important part in the organization of geological work both here and abroad. As an assistant on the Second Geological Survey of Pennsylvania and as a member of the International Congress of Geologists his services were especially important.

General Mining News.

ARIZONA.

COCHISE COUNTY.

The Copper Queen Mining Co. is installing a new system for holding 'swelling ground'. On the 300-ft. level of the Holbrook a drift was run in February and timbered with 12 by 12-in. sets. A month later they had to be renewed. These are now to be replaced by posts and caps made with 6-in. I-beams weighing 18 lb. per foot. As the depth of these posts and caps is only one-half of what it previously was with timbering, there will be a material saving in the amount of ground excavated, estimated to be 35 cu. ft. per set. In other parts of the mine timber treated with creosote is being used; also reinforced concrete in the hot parts of the mine where timber soon rots and gets put out of condition.—What is pronounced one of the best ore strikes ever made in the Warren district has been encountered on the 600-ft. level of the Shattuck mine. The sample showed 38% copper and is solid carbonate with a manganese coating. The find was made in the No. 22 raise which was recently started north on No. 8 cross-cut, the raise now being in about five feet of this ore. Development was begun by the Shattuck-Arizona Copper Co. in 1904, and has been prosecuted with great vigor. Byron Pattison is superintendent.

GILA COUNTY.

The special meeting of the Superior & Boston Copper Co., called for the purpose of authorizing an increase of the capital stock of the company from 200,000 to 250,000 shares, has been held in Globe. The increase was authorized unanimously, and will be offered to shareholders of record at \$12 per share. At the Great Eastern mine a fine body of copper ore has been developed between the 400 and 450-ft. levels. The new McGaw shaft is being opened rapidly by sinking and raising at the same time, and should be down to the 600-ft. point in the middle of June. W. E. Carter is superintendent.—The Cactus Development Co. is meeting with success in the development of the Arizona National and Pinto Copper properties, situated on Lower Pinto creek, in the western part of the Globe district. The shaft on the Arizona National is down over 400 ft. and the last 200 ft. is in ore, which at the present depth is carbonate and sulphide. The mine is four miles west of the Miami, and has Thomas W. Hamilton as general manager.—George E. Gunn, general manager of the Inspiration Copper Co., is reported to have said that results of exploration will not be known for about two months. The sinking of two shafts and driving of two cross-cuts and one drift are progressing, and the showing of ore thus far is encouraging. One churn-drill has been delivered on the property and will be in operation within a few days, and the installation of another drill will soon follow.

For the past week engineers of the Southern Pacific have been surveying for a line of railroad to connect Cutter on the main line of the Gila Valley, Globe & Northern with the Arizona Commercial railroad at its terminus near the Eureka shaft. The new road will not exceed seven miles in length, and will not require more than a 2% grade. The proposed branch from Cutter will serve the Arizona Commercial, Iron Cap, Superior & Boston, Arizona-Michigan, and Superior & Globe companies, and will soon be a necessity to relieve the congestion of freight.

MARICOPA COUNTY.

The Central Arizona Electric Power Co. has nearly completed its transmission lines to the Octave mine, and will enable operations to be renewed which were abandoned in August 1908. This gold mine is over 1000 ft. deep and has on that level a 5-ft. vein worth over \$16 per ton. It is planned to sink the Joker shaft to 1800 ft., and to make connections with the No. 3 shaft of the same property. C. E. Meisse is president, W. W. Wishon general manager, and M. W. Ditto consulting engineer.

YAVAPAI COUNTY.

The Arizona Power Co. is building three electric sub-

stations, one of which has already been completed in the Jerome district. It will supply 1500 hp. to the United Verde Copper Co., where George W. Hull is engaged in completing the Cleopatra smelter. Arrangements have been made for delivery of coke and flux, and Hull has over 2000 tons of 14% copper ore on the dump. A new 150-hp. compressor and a hoist have arrived, together with their motors. This company has taken a long time to get down to serious work, and it is hoped that the smelter may soon be blown-in.

YUMA COUNTY.

Preparations are being made by the Daly Mines Co. to operate the Vulcan group adjoining the Mundersbach property, about 12 miles from Bouse. The ore extracted on the surface is oxidized and contains from 2 to 10% carbonate and oxide of copper, with \$3 in gold and silver. Carroll J. Daly, of Los Angeles, is president of the company, and has engaged E. A. Haggott as consulting engineer. About a mile from Winchester another gold strike has been made on the Anaconda claims belonging to J. D. Mitchell, of Salt Lake, W. H. Slaughter, and J. T. Hemperly. Winchester is only two miles from the railroad station at Vicksburg and about ten from Salome. Since the discoveries of a month ago the population of these small towns has increased very considerably.

CALIFORNIA.

BUTTE COUNTY.

Harrison Appel, who has been manager of the El Oro and Butte dredges at Oroville since they began operations, has severed his connection with the company to devote his time to mining some claims in Sierra county.

CALAVERAS COUNTY.

The Melones Consolidated Mining Co. is driving a 12 by 11-ft. adit under Carson hill, and has done about three miles, leaving two more to be done. It is equipped with electric cars.—The Reiner Mining Co. has installed a 150-hp. compressor, and is now placing rock-breakers and milling machinery. The Cornish pump has been moved to a more advantageous position, and production is expected to be started this month.

ELDORADO COUNTY.

The Last Chance mine at Coloma is to be re-opened by L. N. Stricker, J. F. Owen, and A. Shafsky, of Placerville. It has been worked by many different parties with varying results, but never on a very systematic plan.—A 12-ft. quartz vein has been discovered by A. Sciaroni at his mine $3\frac{1}{2}$ miles north of Grizzly Flats, which shows free gold in the pan, and also carries a good percentage of galena.

INYO COUNTY.

The Mono Consolidated Copper Co.'s property in the White mountains has been bonded to J. Vernon McConnell, of Los Angeles, for \$75,000. The property consists of 12 claims near Hamil station of the Nevada & California railroad, and is considered a valuable low-grade copper prospect. The former owners were John Shortall, H. Levinson, J. S. Johnson, and others.

MONO COUNTY.

The Standard mine is working 80 men, and has recently improved the mill and will enlarge the cyanide plant.—It is understood that negotiations are under way for a transfer of the Yellow Aster mine at Randsburg to a New York corporation for about a million and a half dollars.—Holbrook, the new copper-gold camp in this county, is receiving considerable attention, and a number of strong veins are being developed; but sufficient has not yet been done to estimate the value of the camp.

NEVADA COUNTY.

The Lecompton mine will not be closed down as has been reported, but will be continued under the direction of Samuel Colt, who at present is at Santa Barbara. The mine is open only to the 200-ft. level, beyond which it is still full of water. The heirs of the late A. M. Gilbert own both the Lecompton and the Norambagua, and have decided to continue working the latter mine as well. It has a shaft over 400 ft. deep.—The 10-stamp mill built by a

local iron works has been completed and sent to the Golden Gate mine at Grass Valley.—The last load of machinery for the 10-stamp mill to be erected at the Black Bear mine has arrived at the property, and will be immediately put together. The mill is practically new, having been used but a short time by a company operating near Auburn, in Placer county, and is expected to give satisfactory results.—A. H. Tickell has filed a claim to 5000 in. of water in the Middle Yuba river at a point above the dam used by the Plumbago Mining Co. to divert the water for power purposes. He intends to build a power-plant on the Nevada county side of the river that will generate at least 500 hp. and transmit it to the Graniteville, Alleghany, and Forest City mining districts.—There is a movement on foot to consolidate the Republic and the National mines in the Graniteville district. The president of the Republic company, E. W. Estes, has gone East to consult with the owners of the National mine, which is operated by the Syracuse & California Gold Mining Company.

PLACER COUNTY.

Three wagon loads of machinery have arrived at the Annie Laurie mine, where development is being actively pushed by Captain Hooper. Three new adits have been started and a compressor is being installed. Water-power will be used, as the required 50 hp. can readily be obtained from the ditch of the South Yuba Water Company.

SAN LUIS OBISPO.

A discovery of rich gold-bearing ore in the workings of an abandoned mine in the San Carpajaro region of the Coast range has caused great mining excitement at San Luis Obispo. It is stated that a quantity of the ore has been broken, and is now awaiting shipment.

SIERRA COUNTY.

It is said that the new vein which was found in the Chipps mine above Sierra City, is between 10 and 12 ft. wide, and will mill throughout not less than \$10 per ton.—The Cleveland mine, on the south side of the South Fork between Sierra City and Downieville, has been bonded to John W. Shinn, of New York. Shinn has had experience in the Sierra City district and will prospect the Cleveland on a systematic plan.

SISKIYOU COUNTY.

The Scott Bar Hydraulic Mining Co. is engaged in constructing a 25-mile ditch in the Scott Bar region, capable of carrying 2500 miner's inches of water. It will cost upward of \$100,000 to complete. About 13 miles of ditch have now been built.

TEHAMA COUNTY.

At a point 20 miles north of Red Bluff it is reported that a seam of good-grade coal has been discovered while blasting the bank on the side of a road. William H. Bergh has located six claims on the best part of the ground.

TUOLUMNE COUNTY.

The group of claims held by the Horseshoe Bend Gold Mining Co. has been sold to the Empire Gold Mining Co., to the great pleasure of the inhabitants of the region, who contend that the former company never did any honest, intelligent mining. George Morrice will be the manager of future operations, and will immediately start shaft-sinking and install a suitable hoist. Previously there have only been corkscrew tunnels and gopher holes.—An air-compressor and machine-drills will be installed at the Mangante mine.—The mill at the Omega mine is undergoing changes and is being enlarged. Ten more stamps will be installed.

YUBA COUNTY.

The Black Swan gravel mine, on Mooney Flat, near Smartville, is to be re-opened, in connection with other property, by the Sowell brothers, who have already taken the preliminary steps to install the necessary machinery to provide against flooding. This is what caused the Black Swan to close down a couple of years ago, when G. W. Manwell was manager.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—When the compressor for the Joplin Mining, Milling & Tunneling Co. arrives this week the Washington adit will be advanced to cut the Gambetta vein, about 900 ft. distant. During the last week 23 tons of lead ore were shipped to the local sampler, and brought returns of 60% lead, 40 oz. silver, and 0.5 oz. gold per ton.—It is reported that the Princess of India adit on Columbian mountain, will be advanced next month. It is now in over 1000 ft., and it is intended to drive 900 ft. farther to cut under the American Sisters vein at a depth of from 700 to 900 ft. under the present workings. A compressor is to be installed, driven by electricity furnished by the power-plant two miles below Georgetown. As soon as the American Sisters vein has been reached, it is the intention of the manager, J. J. White, to move the 25-ton concentrating mill from the upper workings to a site below the dump of the Princess adit.—Work has been resumed upon the Butler mine. The adit is being driven ahead, while the shaft is to be sunk another 100 ft. E. M. Moscript, of Idaho Springs, who is constructing a concentrating plant for the low and medium-grade ore exposed, expects to have the mill ready during the next 60 days. It will also treat custom ores, a contract having been entered into with S. D. Coffin, manager of the Coffin mine for the milling of his ore.—Work has been resumed upon the Mazeppa group of claims, situated on Democrat mountain. The adit, in 700 ft., is to be driven ahead, while drifting is to be put under way upon the Mazeppa vein which was intersected about a year ago. M. Jacoby is manager.

Georgetown, April 23.

The Smuggler mine in the Brown Mtn. district passed to the control of the Hollingsworth Mining Co. a few weeks ago, for \$22,000 in cash. The shaft is now 300 ft. deep, and the management intends sinking another 150 ft., with drifts 75 ft. apart. Lessees who have been extracting ore will be permitted to continue their work. Several of them have taken out very high-grade ore, alongside of which is 3 ft. of mill grade which is concentrated at the Terrible mill. The Smuggler and other veins in the group run parallel with the Terrible and Dunderberg. The Terrible has been worked to a depth of 1465 ft., the ore-shoots having been found to be continuous. Both veins will be worked together.

LAKE COUNTY.

T. J. Dalzell, the Commissioner of Mines for Colorado, has published the mineral statistics of the State in the past year showing that the total gold production was \$22,695,575, of which Lake county is credited with 67,383 fine ounces, worth \$1,392,800. The county also produced 3,216,000 oz. silver, 14,380,000 lb. lead, 5,330,000 lb. copper, and 23,400,000 lb. zinc, with a total value of \$5,461,000.—The Langola Mining Co., which has been operating the Pyrenees and R. A. M. properties for the past year or more, has temporarily suspended operations on account of the difficulty in handling the water. However, arrangements are being made to install a pumping plant of greater capacity. Pumping had been maintained to a depth of 1150 ft., when it became too heavy to cope with. It was then ascertained that the company was handling the water from the Wolfstone and Greenback properties as well as its own; and up to the present the Langola company has not been able to arrange for co-operative pumping with these other two mines.

OURAY COUNTY.

Over 1000 ft. of headway have been made in the Kohler tunnel of the San Antonio mine near Red mountain, and another called the Robber tunnel has been advanced about 800 ft. At present all ore is being taken out through the Carbon Lake shaft, and the expense of hoisting and hauling will be materially reduced when these tunnels are completed. John Roper, the manager, reports that 4110 tons of ore were shipped to the Durango smelter in the 6 months preceding February, averaging 11% copper and netting \$16.89 per ton.

TELLER COUNTY.

It is estimated that \$550,000 will be required to complete the 15,500 ft. of the Cripple Creek Drainage tunnel, and of this amount only \$388,500 has been subscribed by the mining companies of the district. The plan is to assess the various companies proportionately on the basis of benefits to be derived. The Colorado Springs Mining Stock Association has been asked to contribute \$5000 to the fund. A committee, consisting of Frank G. Peck, president of the Portland, A. L. Burris, president of the El Paso, and F. F. Castello, president of the Mary McKinney, is making a campaign to raise \$160,000 needed to complete the work, which will give a new lease of life to the entire Cripple Creek district.

IDAHO.

ADA COUNTY.

The Black Hornet district, 12 miles east of Boise, is more active than it has been for a number of years. At the Hornet mine roads and buildings are being constructed, and a shipment of structural steel with parts of a 30-stamp mill has recently arrived. Power will be secured from an electric plant at the Barber dam. The Viola mine has been acquired from the War Eagle Mining Co., and is said to be in well developed condition.—Half a mile north of these claims lies the Adelmann group, controlled by A. Adelmann of Boise. He believes his ore to average \$12 in gold, and hopes to build some plant for treating it. The ore, however, is not suited to the cyanide process.

BOISE COUNTY.

Robert Abernathy, of Spokane, president of the Golden Age Mining Co., operating in Boise basin, where an important strike was reported a few days ago, announces that 15 stamps will be dropping in May. When work was resumed last winter and the adit had been advanced 486 ft. an orebody 3½ ft. wide was encountered assaying from \$20 to \$40 per ton. The latest strike is on the 300-ft. level. The property is financed by the owners and no stock has ever been offered for sale.

ELMORE COUNTY.

The Minerva mine is working the Minerva lode at Atlanta, parallel and 2000 ft. west of the Last Chance lode. Thirty men are employed. The mine is developed by a cross-cut adit 850 ft. long intersecting two veins 50 ft. apart. But little work has been done on the first vein, though it shows some good ore. The second vein has been developed about 400 ft. on each side of the cross-cut. The ore is conveyed by a gravity tramway 1800 ft. long to the 10-stamp mill on the Yuba river, which has been in operation for several months. As the ore is mined near the surface, a good extraction is made by amalgamation. Two years ago the company installed a patent cyanide process for treating the tailing, but it proved a failure, and the tailing is being stored for future treatment. The company intends to drive a cross-cut adit from the level of the mill to cut the vein 1200 ft. below the present workings.—The Atlanta Gold & Silver Mining Co. has resumed work on the Atlanta lode after a shut-down of 7 or 8 years. The mine has been developed by a number of adits, most of which have caved, but one of the principal is being re-opened. A 20-stamp mill on the Yuba river belongs to the company and will be remodeled this summer.—A number of small prospects are also being worked, and the outlook of this camp, one of the most beautiful in the State, is brighter than it has been for years.

IDAHO COUNTY.

Reports of a new strike from the Ten Mile district have caused quite a stir in Central Idaho. It appears that Dan Bennett has found a 26-ft. vein near Newsome that pans free gold at any point in its width. The discovery was not announced till Bennett and his friends had taken up all the best ground, and the inaccessibility of the district has also tended to keep out the stampedeers who invaded the Four Mile district about a year ago.—The Knob Hill mine has

been sold to Frank Peck, manager at the South Fork mine. It is reported that a number of other claims on Knob Hill are about to change hands. The Knob Hill mine is southeast of Orogrande and belonged to Orrin Lamb.—The shaft on the Iron Crown mine, near Newsome, is now down about 62 ft., showing 2½ to 3 ft. of ore that assays \$50 per ton. W. M. Garner has been in charge of the work for W. V. Garrett & Co. of Spokane, who purchased the property last fall.

LATAH COUNTY.

The Mountain Gulch Mining & Milling Co., headed by W. E. Seelye of Spokane, has resumed lode mining on its property in the Hoodoo district, where previously there has only been placer mining. The property has the first discovered gold vein in the district and was for years operated by the Taylor brothers, of Farmington. A re-organization was effected by J. J. Browne, W. E. Seelye, and others a year ago, and they have installed a 2-stamp mill and concentrator with a daily capacity of 150 tons. More machinery will be added during the year.

SHOSHONE COUNTY.

It is rumored that the Monarch mine, near Murray, will be taken over by the Paragon Consolidated Mining & Milling Co., which already owns several mines, including the Chicago-London, Paragon, and the Jewell. The Monarch has been developed by five shafts and a long adit, and is under the management of Herbet Auerbach, who is now abroad.—The ground for the new concentrator for the Alice Mining Co. has been cleared and it is expected that the work of erecting the buildings will be begun immediately. The concentrator will have a capacity of 100 tons a day, and funds for its erection have already been subscribed. James F. McCarthy, of Wallace, has charge of the placing of the orders.

A decision of paramount importance to the Coeur d'Alene has just been handed down by the Supreme Court of the State of Idaho in connection with the appealed case of Thomas Wall against the Basin Mining Co. The effect of the decision is that stocks which are marked "non-assessable" cannot be assessed. Wall sued the Basin company for a large number of shares which had been sold at a delinquent sale for non-payment of assessment. The case was tried in the District Court and a decision issued in favor of the defendant company. This decision has been reversed by the supreme court.—Work on the Amy group of claims, which was recently bonded by Spokane men from Gus Smith for \$40,000, has been stopped. The property had only been taken over about a week, and development had just commenced when a representative of those interested came to the district and paid off the men. It is believed that the bond has fallen through, and it is now reported that the property is to be taken over by Portland men. A strike of gray copper ore has been made in the long adit being driven on the property of the Copper King company at Mullian. The strike was made at about 1200 ft. from the portal, but owing to the heavy flow of water the extent of the orebody has not been ascertained. The Copper King claims are being developed through the ground of the Copper Center Co., and it is not yet known whether the present ore lies at the end of the Copper Center ground or at the beginning of the Copper King land.—A small force of men has been set to work cleaning out the workings of the Stewart mine prior to the expected visit of F. Augustus Heinze to the district, when it is expected that a large force of men may be set to work. The company has just acquired three claims adjoining on the east, for a consideration in the neighborhood of \$10,000.—An assessment of 2½ mills per share has been levied by the Bullion Mining Co., and accompanying the notice a statement of the affairs of the company has been mailed to the stockholders. This statement says that it is the intention of the company to sink the shaft another 100 ft. and to install pumping equipment. The financial report shows a large amount to have been expended on development and is considered satisfactory.—A contract for 600 ft. of raising from the 1400 to the 600-ft. levels on the Monarch mine is about to be let.

MONTANA.**LEWIS AND CLARK COUNTY.**

In the United States Circuit Court on April 17, Judge Hunt appointed Cornelius Hedgen and E. P. Walters, both of Helena, receivers for the Bald Butte Mining Co., representing the minority and majority interests respectively. The Bald Butte Co. is one of the most famous of Montana gold producers, and has paid upward of \$1,000,000 in dividends. The action was taken at the request of the Boston creditors.

SANDERS COUNTY.

Martin Cook and M. Woodwell, of Spokane, have taken a contract to run 100 ft. of adit on the Montana Gold Mining & Milling Co.'s property three miles from Heron. The adit will run under the shaft to cut the vein at depth. There is an orebody now exposed in the shaft which runs about \$120 per ton in free gold. Some mining engineers have recently offered to take a lease on the ground and to pay 20% royalty on the ore. Charles Sawdey is manager.

SILVER BOW COUNTY.

The East Butte Copper Mining Co. proposes to increase the capital stock by 300,000 shares to acquire 83% of the holdings of the Pittsmtont Copper Co. This latter company owns 90% of the stock and all the bonds of the Pittsburg & Montana Copper Co., which operates the Pittsmtont mine and smelter at Butte. The mine has been opened to 1500 ft. with the most important development done on the 800 and 1200-ft. levels, where important orebodies have been found. Horace V. Winchell in his report on the mine says that it is not practicable to make an estimate of the ore reserves, but has no doubt that the mine can produce 350 tons per day for several years to come. The production at present is 150 tons of first-class, and 200 tons of second-class ore daily. At the smelter one blast-furnace is operating, and a second is under construction, together with a matting furnace for flue-dust. Equipment at mine and smelter is substantial and represents an investment of over a million dollars. The consolidation will make the East Butte one of the largest mining properties in the camp. Oscar Rohn will continue as general manager.

NEVADA.**ESMERALDA COUNTY.**

The preliminary survey of the Ely & Goldfield railroad has been completed, and the chief engineer, C. M. Rasor, is in Ely awaiting the arrival of John Ryan, the manager of the Tonopah & Tidewater.—The report of the Round Mountain Mining Co. for the year ending March 31 shows that 6775 ft. of work were done. The main incline shaft is now 738 ft. deep, and levels have been opened on the 500, 550, 600, and 700-ft. There are 39,900 tons of ore blocked out, estimated to be worth \$12.30 per ton, and 29,500 tons were taken out during the year at a cost of \$6.07 per ton. The manager, James R. Davis, believes that the installation of machine-drills and electrically operated machinery will reduce the mining and milling costs by 15%.—A large force of extra men will be put to work by the Goldfield Consolidated Mines Co. within the next two weeks for the purpose of drifting north and south on the lower levels. The main shaft on the Clermont is down 1050 ft., and a station is now being cut at the 1000-ft. level. The downward extensions of the ore-shoots of the Mohawk and Red Top are said to be fully as evident at the 750, 875, and 1000-ft. levels as above, if not even more extensive and rich. No drifting or cross-cutting has been done on the Consolidated below the 600-ft. level of the Mohawk claim, which, at that level connects with the Clermont shaft.

NYE COUNTY.

(Special Correspondence).—The Bonnie (Clare M. & M. Co. has been re-organized with a capital of \$1,250,000. One share of new stock will be exchanged for four shares of the old, the distribution to be made by the court following the dissolution of the old corporation. Money realized from sales of stock will be devoted to the development of the Corbett and Rattlesnake claims, where fair grade ore has been

opened up. The mill will be moved from its present position to a spot between the two claims. It is said that the mill will be turned over to a company which will treat custom ore, with special arrangements made for treatment of the Bonnie Clare output. S. F. Owens is president and Don Carlton secretary.—A vein of high-grade ore has been struck at a depth of 210 ft. in the Crown Point Globe, in the 50 ft. of ground leased from the Johnnie Con. The company is straightening its incline shaft, and has opened 20 ft. of the ore. The mine is producing about \$3000 per month.—The Johnnie Con. will sink its shaft to the level of the lower Crown Point Globe workings in hopes of striking the rich vein opened in the latter. At the 700-ft. level a 12-ft. body of ore running \$10 per ton is being worked. A No. 2 Gates 100-ton crusher, retort furnace, amalgamating house, clean-up barrel, and other apparatus have been recently installed. Last month the Johnnie Con. produced approximately \$12,000.

Rhyolite, April 23.

The seventh annual report of the Tonopah Mining Co. of Nevada, covering the period from February 29, 1908, to March 1, 1909, has just been received by the stockholders, and shows that 162,750 tons were milled, averaging \$23.61 per ton. The cost of mining and milling was \$8.96, and the total disbursements were over \$2,700,000, of which \$750,000 were paid out in dividends. The net surplus of the year is \$1,001,098, and there are estimated to be 367,000 tons of ore reserves worth \$21.11 per ton. During the last week an average of 93% of the stamps were dropping all the time, and crushed 3035 tons of ore. Twenty-six tons of concentrate was shipped.—J. V. Priest, manager for the Mogul Consolidated Mines Co., reports that at the main working shaft there are 3000 ft. of workings, for the most part in ore, and much of it high grade. The new vein on the 300-ft. level is 9 ft. wide and worth \$14 per ton. Development is being advanced on the 410 and 550-ft. levels to cut this same vein. Promoters are now in London negotiating for money to build a mill on the company's property.—Acting under telegraphic advice from the president of the Homestake King, S. B. Tyler recently closed down the Homestake mine and mill in Bullfrog. Tyler says that the ore reserves have been so nearly worked out that until more ore is placed in sight in the mine it is unreasonable to continue. He has recommended deeper development, hoping to open additional reserves below the 500-ft. level.—The Pioneer lease has made another sensational strike on the 210-ft. level, and all the machine drills in the upper levels have been moved to the place. An order has been placed for a new 12-drill compressor. An electric hoist is also planned for, to be installed on the 210-ft. level. This is to be used in sinking on the ore.—A complete dredging outfit has been shipped from Sacramento to Manhattan, to be placed on the Wilson ground in the main gulch. This is the result of the recent visit of M. A. Nurse, president of the dredge company, and A. M. McCollum, one of the directors, who spent several days in the placer camp.

WHITE PINE COUNTY.

Spring valley, 6 to 8 miles wide and 60 miles long, is between the Schell Creek range on the west and the Snake range on the east. On the Schell creek slope, facing this valley, are the Siegel, Muncy, Lucky Seven, Piermont, and Goshute mining properties, all partly developed and having ore; on the Snake range side are the Red Hill, White Cloud, and Allen, similarly developed. The Muncy, Siegel, Piermont, and others in Schell Creek range, have gold, copper, and silver ores; those in the Snake being lead and silver. The Muncy belongs to the Schell Creek Range Ore Development Co., the work on which is being directed by E. L. Fletcher and O. McCarney. Their camp on the east slope of the range is 24 miles east of Smelter, and they have finished a wagon and automobile road, having a maximum grade of 8%, between those points. The work done on the Muncy amounts to about 800 ft. The property was examined and recently reported on by Edwin E. Chase, of Denver. The plan is to ship ore to the smelter at Smelter.—The Copper Mines Co. has a group of 55 acres on the Ely copper belt,

lying between the Ruth and Copper Flat groups of the Nevada Consolidated. This is a Gunn-Thompson property, and is superintended by H. R. Plate, of Ely. Within the last year a 2-compartment prospecting shaft has been sunk 240 ft. and levels have been driven from the 215-ft. station; in addition to this 8 churn-drill holes have been sunk, each to a depth of over 600 ft. Much lateral development will be done this year from the shaft to connect with all the drill-holes. This company owns the old Chinaman mine, and it is intended to prospect that ground with churn-drills this year. An additional drill will probably be purchased.

OREGON.

DOUGLAS COUNTY.

A valuable mineral find in southern Oregon has been reported by G. W. Morris, an old-time prospector from California. It is a vein of copper ore carrying \$17 gold per ton, and out-cropping for a distance of 600 ft. It was found about eight miles south of Roseburg.

UTAH.

SALT LAKE COUNTY.

James P. Graves reports that the Bingham Mines Co. has over \$200,000 cash in hand at the end of its financial year. During the year the company has acquired title to the mines and property of the Bingham Consolidated Mining & Smelting Co., but owing to the delay in obtaining possession of this property it has been impossible to operate the mines till recently.

TOOELE COUNTY.

The Boston Sunshine plant is being started near Mercur by John and George H. Dern, to treat about 150 tons of ore per day. Various modifications have to be made in the arrangement of some of the new devices, but in general things are running as smoothly as can be expected. At the Ingot mine in the same region Dern is drifting along a fine-looking vein at a depth of about 1000 ft., but so far it has not proved to be of commercial value.

WASHINGTON.

FERRY COUNTY.

The Southern Republic Mining Co. has been organized by O. B. Hollis and A. R. Sweet, of Spokane, G. M. Fripp, of Grand Forks, and J. T. Hollis, of Waverly, to operate a group of claims adjoining the New Republic property on the south. The surface ore runs from \$6 to \$50 per ton and is a continuation of the vein of the New Republic. Professor Aughey, of Spokane, who made an examination of the property, believes that it will turn out as good as the New Republic mine.

STEVENS COUNTY.

Announcement is made that construction work on the Spokane, Wallace & Interstate railway will begin in a short time. The line will be 84 miles long, the distance from Wallace to Coeur d'Alene being 52, and from Coeur d'Alene to Spokane 32 miles. The present time required for the trip to Spokane by way of Harrison and Coeur d'Alene is five hours.—C. C. Anderson's ranch in Black canyon, six miles east of Northport, was the scene of a rich gold strike on April 21, picked samples assaying \$740 per ton. Considerable excitement ensued and a number of prospectors have gone into the canyon to stake out claims. Anderson found traces of gold in an old creek bottom near his cabin some time ago, and followed the course to the hill above, where he has since done active work, and from which he took the samples.

CANADA.

BRITISH COLUMBIA.

Le Roi No. 2 shipped 2620 tons of ore to the smelter in March, and received \$62,300 in payment of previous shipments. This company is employing 125 men at the mine and concentrator, while there are 410 employees at the Centre Star group; other small properties make up the total number to 565 men. When the other Le Roi resumes it is hoped there may be 800 men at work, as there were in 1908.—Mining prospects in the Lillooet district are looking bright. On Cayoose creek, a placer proposition controlled by the

Vancouver Enterprise Co., is being worked with 18 men, operations having been started recently. In addition to this, work has opened up at a hydraulic mine on Alexander creek, a tributary of Bridge river, and work has also been started at the Ben d'Or mine. This last mentioned is a gold quartz mine, and the stamp-mill will be started as soon as weather conditions permit. The gold dredge which has been operating on the Fraser river at Lillooet is now at work.

ONTARIO.

The King Edward mine at Cobalt began active work in the early part of 1907, when a 13-drill compressor and two 100-hp. boilers were installed. There are now in the mine 7500 ft. of drifts and 1230 ft. of shafts and raises, developing four productive veins. The most recent vein discovered is characteristic of the King Edward, being about 3 in. across and carrying between one and six thousand ounces of silver per ton. A 10-stamp concentrator treats the ore. The high-grade which averages 2500 oz. per ton is picked out, and all the rest of the ore goes to the mill, which treats about 20 tons per day. The milling ore runs in bulk 45 oz. per ton. About 15 tons of concentrate are produced monthly. It is quite likely a larger concentrator will be installed later. Glenn Anderson has charge of the mine with a force of 70 men.—An order-in-council was issued on April 21, throwing open 1,439,300 acres of land in the Algoma district for prospecting. The land lies north of Sault Ste. Marie, and the Government has good reason to believe that there are valuable minerals on the property.

Official figures show that the ore shipped from Cobalt in 1908 contained 19,394,496 oz., valued at \$9,112,746, and the by-products of cobalt and arsenic brought the total value for 1908 up to \$9,229,768.

YUKON TERRITORY.

The records for the fiscal year ending March 30 show that during the previous 12 months 288 quartz claims were staked, no less than 40 of which were located and recorded in March. The heaviest staking was done last July, when 58 were offered for record. The first quartz claim staked in the territory was recorded in August 1894, since when over 1000 have followed suit. The largest aggregate belongs to the Dawson City Quartz Mining Co., which possesses 19 claims.—A hundred sacks of ore from the Jupiter-Mars property on Chatham creek has been put through the business men's stamp-mill, and netted an average of \$20 per ton on the plates.

MEXICO.

CHIHUAHUA.

J. Gordon Hardy, manager for La Republica Mining Co. in the district of Rayon, has almost completed installing the additional plant at the company's mill. There will now be 15 stamps, two tube-mills, Wilfley concentrators, and the cyanide plant. The present output is about ₧80,000 per month.

DURANGO.

It is reported that the machinery and equipment of the Compania Nacional Mexicana de Hierro y Acero are to be sold. This company has been working the famous Iron Mountain, or Cerro Mercado, with a force of 200 men under the direction of T. F. Witherbee. The latter has estimated a tonnage of 350,000,000 of specular hematite to be available for smelting with an average of 63% Fe and an inconsiderable amount of phosphorus. The main thing that has prevented the Iron Mountain from becoming a prodigious producer has been the untoward expense of fuel.

JALISCO.

It is reported that the Magistral-Ameca Copper Co. will erect a smelter instead of a concentrator, to have a daily capacity of 150 tons per day. H. L. Percy and James P. Harvey, vice-president and manager of the company, have ordered the required plant in Denver.—The Amparo Mining Co., operating near Etzatlan, will pay its second quarterly dividend on May 10, at the rate of 2½%. A Burt filter is being installed in the cyanide plant. James H. Howard is general manager for the company.

Special Correspondence.

MEXICO.

Protection for Mexican Coal.—Costs of Living.—Jalisco Power Concessions.—Amparo Mill.—Presidential Message.—Railway Improvements.—Colima.

The railroads and coal producers of Mexico have won their fight for either a duty or a discriminating freight rate on foreign coals and cokes, and the President has authorized the issuing of instructions to the railroads to increase the freight rate \$1 per ton on all coal and coke entering Mexico by Vera Cruz, Tampico, or Laredo. The rate on coal and coke entering by El Paso is not raised, as it is understood there is already some kind of a differential rate applying there, and also the longer haul for material entering through that gateway gives the home product greater advantage than it enjoys at other points, even with the increased rate. At Chihuahua, however, foreign coal and coke can be laid down cheaper than the native fuel. This is a clever move by the Mexican Government, for, having control now of practically all the trunk lines of the Republic, this method of increasing railroad receipts strengthens materially the securities of the National Railways of Mexico. In another sense, however, it is a somewhat suicidal policy. Mention has been made before in these letters of the heavy burdens that had to be borne by the mining industry throughout the Republic, by reason of the excessive tax on every article of consumption and of production, as well as high transportation charges, and it was shown that any increase in the cost of fuels would eventually have to be paid by the miner. The low prices of the metals may be borne with patience, for there is the hope and belief that it is only temporary; but the cost of everything now frightens him. Time was when a person could live in Mexico for the same number of pesos that it cost him in dollars in the United States; but it is not so now. The production of the country is not equal to the demand, and prices have risen; foreign articles, that were once obtained at a reasonable figure, went up in price with every rise in exchange, and never were lowered; the Mexican duties have steadily risen, and within the last six months they have again been raised, in some instances as high as 60% above the former tariff rate. As a consequence the costs of living and all other expenses and supplies, whether for the home, mine, or factory, are now as high in Mexico in actual gold money as in the United States, and in many cases higher. This takes away many of the former attractive features, there remaining then only the lack of great competition and opportunities for enterprises of large capital, which the Mexican has not at his command. It is no longer the country for the poor man.

The more accessible mining interests of Jalisco, that is, the properties about Ameca, Etzatlán, and Hostotipaquillo, are considerably elated over the merging of the Cuesta and Pimental concessions and companies on the electric power and transmission lines through the said districts, for, while it may mean a reduction of competition, and possibly a higher cost for power, it means undoubtedly a larger capital in one enterprise without the necessity of duplication, and a consequent more prompt realization of the desires of these mining districts. The recent splendid finds at El Favor, Cinco Minas, San José de Ventanas, and the Buena Vista, in the Hostotipaquillo district, make them, as well as others nearby, most anxious for the electric power, that they may more economically increase their operations and productions. The contemplated improvements at the Magistral copper mines, near Ameca, in the shape of a 150-ton reverberatory smelting furnace, will be installed in time to take advantage of the electric power line. The Amparo Mining Co. of Etzatlán, whose recent report showed such excellent results from the Santo Domingo mine and mill, will also be about ready for an addition to its mill by the time the wires reach it. The Burt filter, designed by Edwin Burt of El Oro M. & R. Co., is being placed in the Amparo mill to handle the slime, and if it proves a success others will be

added. Felipe Hueso is supposed to have sold his mining interests in Ayutla to Americans for \$30,000, and it is to be hoped these properties may now be opened up, as their showing deserves. Mr. Hueso has been working them to the extent of his capital for a number of years, doing a little reverberatory smelting; and for generations back they have been a means of livelihood to many in that part, as the many copper utensils in use by the natives bear witness.

The President's message to the Mexican Congress that convened on April 1 was a general review of the country's affairs. Attention was called to the saving at Cananea by the use of fuel oil brought in free of duty under a Federal concession, and the statement was made that a like concession had been made to the Banco del Oro Mining Co., of Magdalena, Sonora, and would be granted to others that might apply. It was expected that at this session of Congress an endeavor would be made to obtain from Congress some measure for the increased use of silver. As yet, however, no move has been made. The banks are endeavoring to encourage the people, but the price of metals continues low and depresses the mining industries. Little rain has fallen, there has been no spring sowing, and there is consequently little work in the agricultural districts. Numbers of people are in actual want. Unless rain comes serious uprisings or bread riots are predicted. Assistance may be given through railroad construction in connection with the Chihuahua & Pacific, the Southern Pacific, and the National

Colima.

Railways of Mexico, all of which have planned important improvements. These on the old Mexican Central line alone amount to \$12,000,000, which can be paid from the estimated saving by reason of the railway merger. The broad-gauging of the Interoceanic is also planned.

The volcano of Colima is again showing great activity, reports stating that lava is being emitted in large quantities, that being an unusual phase for this mountain. The eruption is accompanied by extensive earthquakes, which have involved an area as far south as Oaxaca. Immense quantities of volcanic ash are said to have fallen in the city of Colima, which lies some leagues distant from the base of the volcano.

WASHINGTON.

Taft on Conservation. — Tariff on Zinc and Iron Ores. — National Academy.—Assessment Work.—Forestry.

President Taft has declared in favor of the forest and conservation policies advocated by Mr. Roosevelt. The announcement which was made by Gifford Pinchot in behalf of Mr. Taft is as follows: "Any statement that President Taft is not in sympathy with forestry and the conservation movement is without foundation. On the contrary, I am authorized by the President to say that he is in entire sympathy with the forest policy and the conservation policy as already developed, and stands behind them. I am also authorized by the President to deny categorically the story that great areas are to be thrown out of the national forests by presidential proclamation."

It is a safe presumption that when the tariff bill finally

passes both houses a great many interests will be displeased. After the House and Senate had agreed to a duty of 1c. per pound on zinc in imported ore, which was to keep out Mexican ore, it was thought the matter would end. Representatives of the smelters have, however, told Senator Smoot that this duty would result in Mexican ore being sent to England, to the injury of American smelters. Senator Smoot, who is handling this schedule for the Senate, announced that the smelters and producers would have to get together and come to some agreement. A compromise duty of $\frac{1}{2}$ c. per pound, with ores containing 25% or less of zinc admitted free, has been suggested. The Senate in reporting the tariff bill placed a duty of 25c. per ton on iron ore. Ore is now paying a duty of 40c., and the United States Steel Corporation is supposed to be insisting upon at least 30c. The story is being told in Washington that Andrew Carnegie has lined up with Charles M. Schwab of the Bethlehem Steel Co. for free iron ore. Carnegie, it is said, always believed in Schwab, and did not like it when the steel trust threw the young man overboard. The United States Steel Corporation gets its main supply of ore from Michigan and Minnesota. Mr. Schwab gets a portion of his ore supply from Cuba. It would mean much to him to get his ore free. Members of the House all took a fling at the Standard Oil Co. when they placed petroleum on the free list. It was a popular blow at the octopus, and they were all happy. Independent oil producers and refiners now, however, protest, asserting that the Standard Oil Co. produces only 11% of the crude petroleum in the United States, while the independents produce 89%. The Standard Oil refines $82\frac{1}{2}\%$. The independents ask for an ad valorem rate of 50% on crude petroleum and all products thereof, and also ask that these products be excepted from the drawback clause of the Payne bill.

At the meeting of the National Academy of Sciences which closed here Friday the following new members were elected: Joseph S. Ames, Johns Hopkins University; Oskar Bolza, University of Chicago; Henry Crew, Northwestern University; Waldemar Lindgren, U. S. Geological Survey; Thomas H. Morgan, Columbia University; Maxime Bocher, Harvard University; F. W. Clarke, U. S. Geological Survey; John M. Clarke, State Geologist of New York; and Henry L. Wheeler, Sheffield Scientific School. Foreign associate members were elected as follows: Prof. Albrecht Penck, University of Berlin; Prof. Gustav Retzius, University of Stockholm; Prof. Wilhelm Waldeyer, University of Berlin; and Prof. Wilhelm Wundt, University of Leipzig. The next meeting will be held in November at Princeton, New Jersey.

William H. Andrews of Albuquerque, delegate from New Mexico, has introduced a bill to suspend the requirement of not less than \$100 worth of labor on each mining claim during each year, so that these claims shall not be subject to forfeiture for non-performance of the annual assessment work. The claimants of any mining location, in order to secure the benefit, are required to cause to be recorded a notice that they in good faith, intend to hold and work their claims. Kanute Nelson, Senator from Minnesota, in a bill which was referred to the Committee on Public Lands, seeks to amend the statutes so that in the district of Alaska any person asserting an adverse interest to a tract of land sought to be patented shall, during the period of posting and publication, or within 8 months thereafter, file such claim, and within 60 days begin an action to quiet title in a court of competent jurisdiction. After judgment has been rendered the party entitled to possession shall pay to the receiver \$5 per acre for his claim, together with the proper fee.

Simon Guggenheim, Senator from Colorado, proposes that for instruction in forestry in the agricultural colleges and experiment stations the sum of \$2500 be appropriated each year for each school or experiment station. Mr. Guggenheim specifies that the instruction in forestry shall deal with the management and care of wood lots and forests, and the planting of forest trees, and may be conducted in any manner best adapted to reaching the largest number of persons, but shall not be used for the purpose of educating

technical or professional foresters. A concurrent resolution by Willis C. Hawley, Representative from Salem, Oregon, declares that it is against public policy and unlawful to annul or otherwise dispose of any portion of the public domain, by constructive establishment of Indian reserve or for any other purpose, or any specifically granted lands, to the several States subsequent to the granting act, without first making an equitable adjustment by adequate indemnity. J. K. Kalaniana'ole, Delegate from Honolulu, Hawaii, has introduced a bill extending provisions of the Reclamation Act to Hawaii. Another attempt is to be made to provide a building for the United States Geological Survey. Today S. Guggenheim, Senator from Colorado, introduced a bill providing for a new building and site, to cost not more than \$1,100,000. No plan is to be selected that cannot be executed for \$950,000. The bill seeks to create a building commission, with the Secretary of the Interior, the Superintendent of the Capitol, and the Superintendent of the Library of Congress as members.

DENVER, COLORADO.

San Juan District.—Activity near Crestone.—Clear Creek County.—Wyoming Oilfields.—New Railroad Planned.—Cripple Creek.

The San Juan district is beginning to be visible after one of the hardest winters in its history. In some places where the power lines have been carried on poles 30 ft. high it was found necessary to splice these to keep the lines out of the snow. The recent warm weather has caused a few slides near Ouray, but no serious damage has been done as yet. That portion of the San Luis valley known as the Baca Estate has been purchased by the Baca Land Grant Development Co. and divided into tracts suitable for agriculture and for mining. Prospecting permits and leases are freely granted. Lessees have already opened the old Independent mine near Creston, idle for the past five years. The mining and timber land on the grant will be sold by lottery after it has been thoroughly prospected. About a year ago there was considerable excitement at Silver Plume over connecting the Burleigh tunnel with the Seven-Thirty shaft through the Phillips raise. The event was anticipated with interest, as the water in the shaft was 700 ft. deep. The old surveys were evidently incorrect, since the shaft was not encountered at the point expected. The contractor having made the raise according to his agreement left the work. The management of the Seven-Thirty mine has since been considering the best means of completing the work. It has been decided to pump the water and then make the connection. The pumps are now being assembled. The old Symonds Forks mine at Central City has been awarded to F. Sternberg by the decision of the Supreme Court reversing the decision of the District Court. This mine is one of the oldest and best locations on Quartz hill.

The Northwestern Oil Refining Co. has begun the erection of a refinery at Crowley, Wyoming. The greater part of the machinery and the pipe for the line to connect the refinery with the Byron field is on the ground. The Lander Oil Co., of Lander, Wyoming, has a lease on 4000 acres in the Wind River Indian reservation. A prospect hole has been started by this company. The Treasure Mountain R. R. Co. was incorporated in Denver, on April 12. The road will extend from Redstone, in Pitkin county, to Anthracite, in Gunnison county. It will connect the quarries of the Crystal River Marble Co. with the Crystal River railroad, and will also give an outlet for the Tewksbury Mining Co. The new quarries will compete with the quarries at Marble, which have already made Colorado famous as the producer of large blocks of excellent marble.

Another case of high grading has been unearthed by the management of the Golden Cycle mill at Colorado City. This is the second case discovered at this mill within the last 3 months. About \$5000 has been recovered. The shipments from Cripple Creek have been heavier thus far than for any month of the year. The Doctor Jack Pot Mining Co. has filed suit against the Work Mining & Milling Co. to recover the value of ore amounting to \$2,245,000. It is

claimed that the Little Clara vein on which the defendant company has been working for the last two years has its apex on the Doctor Jack Pot property. The Vindicator Consolidated Gold Mining Co. has issued a circular, announcing that the regular quarterly dividend due on April 25 will not be paid, owing to the poorer grade of ore encountered, and to the payment of taxes. This company has paid 43 dividends amounting in all to \$1,980,000. M. B. Burke and associates have secured a long-time lease on 17 acres of ground on Beacon hill belonging to the Black Belle Gold Mining Co. The Union Leasing Co. has contracted to furnish the compressed air. A trial shipment has already been made from a stope at the third level of the Black Belle shaft.

KALGOORLIE, WESTERN AUSTRALIA.

Chaffers Mine.—February Output.—Vacuum Plants.

There is little to report for February, with the exception of good diamond-drill results in the Associated, and a more favorable outlook for the South Kalgurli. In the Chaffers mine, at the south end of the belt, underground development was disappointing, but in the cross-cut at the 200-ft. level a lode 5 ft. wide, assaying \$14 per ton, was passed through.

The State's gold output for the month was valued at \$2,553,000, and dividends amounted to \$13,500. The monthly returns from the chief producers were as follows:

Name.	Tonnage.	Value.	Profit.
Associated	10,881	\$108,000	\$ 33,000
Associated Northern Blocks. .	3,410	32,500	13,500
Golden Horseshoe	21,933	251,000	100,000
Golden Link	3,222	31,000	3,500
Golden Ridge	2,170	27,500	14,000
Great Boulder Perseverance. .	16,990	128,000	35,000
Great Boulder Proprietary.. .	14,759	220,000	116,000
Great Fingall	13,140	68,000	500
Hainault	4,728	30,500	1,000
Ivanhoe	18,023	205,000	105,000
Kalgurli	10,020	135,000	75,000
Lake View Consols	7,306	53,000	12,000
Oroya-Brownhill	10,585	99,000	40,000
Oroya-Black Range	4,410	55,000	20,000
Sons of Gwalla	12,170	102,000	35,000
Sons of Gwalla South	1,800	23,000	6,500
South Kalgurli	9,033	61,000	14,000

The Cassel plants at work here on old residue treated 27,639 tons, for a return of \$29,500. A vacuum plant is being erected on the Great Fingall in the Murchison. The treatment of slime by vacuum process is gaining ground in this State, yet in Kalgoorlie alone filter-presses are responsible for a monthly return of 100,000 tons. During 1908 Western Australia produced 7757 tons of copper ore, giving a return of 1112 tons copper.

BISBEE, ARIZONA.

Calumet & Arizona. — Superior & Pittsburg.—Copper Queen.—Great Western, Courtland.

A new orebody has been opened recently in the Calumet & Arizona on the 1150-ft. level near the end-line of the Sunny Side claim of the Superior & Pittsburg Co. In the Irish Mag claim the ore developments above the 650-ft. level are proving satisfactory, the orebody having been followed 60 ft. above this level. The new Powell shaft, which is being sunk at the rate of 140 ft. per month, is now 400 ft. deep. Drifting will probably begin on the 500-ft. level. Electric hoists have been ordered for both the Powell and Mag shafts. The Calumet & Arizona Co. is evidently anxious to increase its holdings, as its men are constantly examining new properties. Two of proven value have been found, one, at Courtland, furnishes smelting ore, and the other, near Mammoth, called the Copper Giant, supplies concentrating ore. In the Junction shaft of the Superior & Pittsburg Co., on the 1200-ft. level, oxide ore, the first found in this shaft below the 900-ft. level, has recently been found. The strike is considered important. On the

1400-ft. level, both north and south of the shaft, high-grade sulphide orebodies have been recently found. The Hoatson continues to be the largest producer of this company. The drift on the 1400-ft. level is being driven under the large orebody mined at 1300 ft. About 1000 ft. west of the Cole shaft a body of oxide ore has been developed, and cut through for more than 150 ft. At the Copper Queen all ore is now being hoisted through the New Sacramento shaft except a small amount from below the 1200-ft. level in the Lowell. The cost of fuel has been enormously decreased since the hoisting has been centralized at this one shaft. J. M. Boutwell, formerly of the U. S. Geological Survey, has been making a very careful geological study of the property since last October, both on the surface and underground. This examination is nearing a close. Important results are expected from his work. W. C. McBride, formerly superintendent of the Sierra de Cobre mine in Cananea, one of the Phelps-Dodge properties, has recently been made general manager of the Great Western mine at Courtland, replacing J. H. Talbot. As far as developments have gone, the Great Western promises to be the best mine in the Courtland district. It is expected that the Mexico & Colorado railroad will reach Courtland by the first of July.

GOLDFIELD, NEVADA.

Lucky Boy.—Combination and Fraction.—Florence Goldfield.—Copper Ore Shipped.—C. O. D.

The new vein opened from the Red Top workings of the Lucky Boy claim has been followed for a distance of 60 ft., and shows a fact of 10 ft. of ore yielding from \$50 to \$60 per ton. This ground is being timbered with square sets, and preparations are being made for extensive stoping. The 20-ft. stope at the 600-ft. level of the Mohawk, near the line of the Jumbo, is in a large body of ore of excellent quality which has been proved for 150 ft. A heavy tonnage is being broken from the new Hampton stope of the Combination mine, where the square sets extend for 45 ft. and involve intricate engineering problems. It is announced that work is to be resumed on the Laguna at a point where a vein of good ore was cut at a depth of 718 ft. in the Hazel lease. The Combination Fraction is making a splendid extraction of ore and is treating an average of 90 tons daily at the Nevada Goldfield mill, the average recovery being about \$50.

Development in the Florence Goldfield mine has lately brought to light some new orebodies that compare favorably with the best that property has yet shown. Near the workings of the Little Florence lease, and immediately under the sugar-loaf hill, a vein has been opened at a depth of 200 ft., from which several shipments of high-grade ore have been taken. Sampling across 12 ft. returned \$260 per ton. The orebody has been opened for 50 ft. in the stope and will be attacked shortly from another cross-cut 100 ft. deeper. This is oxidized ore in which the gold is not visible. On the same level and near the workings of the Engineers' lease the vein which appeared two weeks ago as a seam of high-grade ore has now developed in the raise into 7 ft. of ore of shipping quality, with 2½ ft. of exceedingly rich stuff in which the gold can be plainly seen. On the sixth, or 300-ft. level, another vein carries 6 ft. of good milling ore, and nearly under the old stope from which George Wingfield and associates took a fortune in high-grade ore in the early days of the camp, another raise has exposed 10 ft. of \$80 ore. The mill is still handling ore of low grade, not over \$30 per ton at best, and will not begin on the richer ore until the connections are made with the company's shaft. Further sinking in the Daisy mine has been temporarily suspended, and efforts are being directed to opening the ore-shoots at the 500-ft. level, where a station has been cut. The shaft was sunk below the 500-ft. level, and a sump of sufficient depth put down to handle the water. Development is also in progress at the 300 and 400-ft. levels, and daily shipments averaging 10 tons of \$150 ore are being sent to the samplers. Late reports of a discovery of ore on the Great Bend have been exaggerated in the local press, and are emphatically

denied by the officials of the company. An assay was secured, in sampling a stringer exposed in the shaft of the Loftus-Davis lease, which ran \$128 in gold, but there has been no duplicate, and the best the property has to show is a large vein of low-grade ore.

The first shipment of copper ore in the history of Goldfield was sent to the smelter recently from the Gold Bar workings on the C. O. D. Consolidated. A local sampling of the consignment showed the presence of 10 to 20% copper and probably not less than \$100 per ton in gold. Mining has been deferred until the shaft shall have been sunk another 100 ft. from the 300-ft. level. The vein will shortly be penetrated at a depth of 600 ft. from the lease shaft of the Nevada Gold Ore Mines Co., also on the Gold Bar claim. This orebody is more than one-half mile south of the Florence or of any producing mine in the district, and the work is of particular interest from the fact that it extends the proved area thus far. Within a short period Manager Koontz of the C. O. D. has shipped ore from this shaft to the value of \$15,000, all having been taken out in the course of development.

LONDON.

Tharsis Sulphur.—San Domingos.—Jumpers Deep.—Mount Boppy.

The Tharsis Sulphur & Copper Co. in Spain depends less on its copper production than many similar ventures, but none the less it is worthy of note that the dividend during 1908 did not fall below that of 1907, being £156,250, equivalent to 12½% both years. The Tharsis mine does not produce much pyrite, the bulk of the output coming from the Calañas mine. The total shipments of pyrite, washed and raw, amounted to 418,833 tons and the production of copper was 4427 tons. The company has been in existence for over 40 years, and the ore deposits are showing signs of depletion. The company has been investigating properties in all parts of the world, but so far without purchase. The owners of proved properties, knowing that the company has a million and a quarter pounds of cash in its coffers invariably ask for a bigger purchase price than the canny Scotsmen in control are prepared to give. On the other hand, development on prospects undertaken by the company has not yet yielded adequate results. Two properties in Arizona have recently received attention. One of them has been abandoned, and the other, while showing a fair amount of ore, has not yet proved worthy of operations on a large scale. Another pyrite mine in the South of Spain district, though the mine is actually over the border of Portugal, is the San Domingos belonging to the Mason & Barry. This is also showing signs of exhaustion. Instead of accumulating large funds in cash to represent the nominal capital, as has been done by the Tharsis, this company has from time to time distributed extra dividends. Altogether four-fifths of the capital has been returned in this way. The amount of ore extracted and the yield of copper are small compared with the old days, and sulphur is chiefly relied on nowadays for the profit. Less ore is now being placed on the cementation floors, as may be seen from the fact that the ore mined in 1908 was 293,172 tons and the amount sold was 340,439 tons. The profit at the mine for the year was £43,762. Interest on investments brought the total up to £56,701, out of which a dividend at the rate of 30% was paid, being the same as in the previous year. It is not possible to state how long the mine will last, but probably five years is the limit. The mine formerly yielded large profits and it has always been managed and operated with conspicuous business ability.

The prospects of the Jumpers Deep are so good that G. E. Webber recommends an increase of 80 stamps in the mill, bringing the number up to 180. He also recommends 3 more tube-mills, making 5 altogether. The capacity of the mill will then be 42,000 tons per month. In order to provide this new plant and to convert the driving appliances from steam to electric, besides installing a new hoisting plant, it will be necessary to spend £189,500. In the old days the probability is that 60,000 new shares of nominal value of £1 would have been issued at £3. Now, however, the altered methods of finance demand that funds should be provided

out of income. Accordingly £60,249 cash balance in hand will be applied immediately and no interim dividend will be paid. The remaining £129,251 will be provided out of the revenues during the next few years, so that dividends will be temporarily reduced; that is to say, the dividend for the year ending September 30, 1909, will be 5%, a similar sum for the succeeding year, 7½% for the year ending September 30, 1911, and 10% for the year ending September 30, 1912. The whole of the expenditure will then have been provided for and afterward the dividends will probably be about 20 per cent.

The Mount Boppy gold mine in New South Wales owes its success mainly to the late Frank Taylor, head of the firm of John Taylor & Sons. It happened that the property was ready for flotation in November 1899, just as hostilities broke out in South Africa. At that time there seemed little hope of floating anything but a war loan. Mr. Taylor promptly subscribed a large part of the working capital needed for the mine, and in that way made the scheme a success. A few years afterward he also subscribed liberally for capital required for extensions. The mine has fully justified his expectations and has done well for its shareholders. Dividends commenced in 1902 and for the last five years have averaged 45% on a capital of £121,000. During 1908 the profit was £68,228, out of which £57,475 was distributed. The ore treated was 69,557 tons, yielding 34,136 oz. of fine gold, which is practically 10 dwt. per ton. It is estimated that the ore reserves on December 31 last were 126,850 tons, though James Negus, the manager, points out that these figures are necessarily speculative, owing to the irregularities in the width and contents of the veins. The ore consists partly of free-milling oxidized ore and partly of sulphides, and 30 stamps are treating each kind of ore. Additional plant has recently been provided for dealing with the sulphides, such as grinding pans and roasting furnaces. The extra expenditure in this direction has increased the costs, but, on the other hand, has greatly increased the extraction.

PIOCHE, NEVADA.

Day Mine.—Bristol Consolidated.—Prince Consolidated — Pioche King.—Railway Rumors.

The long-promised era of larger shipments from Pioche appears to be at hand. A few weeks ago the Nevada Utah opened another kidney of ore in the Day mine. In this property a system of fissuring in Cambrian limestone runs southwest through the Cottontail, Coyote, and Hillside. The Day and the Hillside have a record of production running into the millions. The Hillside was discovered in 1871. The Nevada Utah has never taken any steps to re-open and operate it, and its old workings in their present condition cannot be safely inspected. At Bristol, five miles from the Hillside, are the ruins of a Washoe mill and two smelters. Bristol at one time had a population of over 500 people. The operations of these plants covered a period of more than 10 years. We know that the Hillside furnished a large proportion of the ore treated, and the enormous dumps at the mine testify to extensive mining, but no one seems to have any full understanding of the nature and size of the orebodies. The Day mine was located in 1877. The first 500 tons extracted are said to have yielded upward of 500 oz. silver to the ton. Day worked this and connecting orebodies down to the sixth level and for hundreds of feet in length. He found them varying widely in size and shape, and extending out from the fissures into the limestone. The fissures themselves carried little ore. The orebody recently opened has been followed from a little above the eighth to the sixth level, where Day missed it by less than 5 ft. The opening on it is already more than 200 ft. long, with a maximum width of 75 ft., and a proved vertical height of 150 ft. Its limits have not been defined, but Mr. Gaskill, the manager, says that it has been explored sufficiently to warrant the statement that it is the largest single orebody ever opened in the mine. Ore-bins of 300 tons capacity have been built at Pioche. A new engine has been ordered for the narrow-gauge railroad from the mine to the station here. The

present equipment is only adequate for a daily output of 250 tons, which can now be mined and maintained indefinitely. Thus far shipments have been restricted to an average of 70 tons per day, because the A. S. & R. Co. at Salt Lake has declined to accept more. Arrangements are now virtually perfected to begin shipping 200 tons per day. It is too early yet to predict what the average tenor of the new orebody will be. Much of the ore contains chloride and bromide of silver. Returns thus far have shown from 18 to 30 oz. silver per ton, with sufficient excess iron and lime to more than cover cost of transportation to the smelter. The ore is put on cars at Pioche at a cost of 90c., including office expenses. Below the 800-ft. level, and for over 300 ft. toward the Hillside, the ground is still unexplored, and Mr. Gaskill intends to continue developments in both directions.

The recent conference between executive officers of the Nevada Utah and the Ohio Kentucky failed to unravel the tangle in titles in which these companies are involved. Conferences were resumed at Salt Lake, and the question is understood to be still open in New York. The mines of the Bristol Consolidated, which lie below the Hillside on the western slope of the range, have been operated only by lessees during the past 5 months. The Mayday and Gypsey of this company, the only mines equipped with hoists, were closed by W. C. Brace, the manager, when he went to New York last fall. Five sets of lessees have been working with the crudest of prospecting apparatus on other mines which the company has never attempted to re-open, but all of which produced much good ore in former days. From 25 to 30 cars of high-grade copper and lead ores have been produced, a considerable part of which has not yet been brought in, because of deep snow on the hillside or deep mud on the roads. In the Prince Consolidated attention has been devoted to the high-grade fissure veins which cut transversely through the formation and are generally referred to as vertical fissures. They have been opened more than 500 ft. along the strike and on the 550 ft. level proved to be fully as strong as on the 300 and 400. Recently the company has been doing a little stopping on these veins. Several cars have been shipped. In addition to the vertical fissures are highly mineralized beds conformable to the bedding planes. One of them, cut in the shaft a little above the 550-ft. level, was 18 ft. thick. After the roads became bad the Mendha cut down its shipments to a car a week, about enough to pay expenses. The production in recent months has all come from the bedded veins. The ore still runs well in gold, with 15 to 25% lead and about 1 oz. silver to each unit of lead. The bedded veins in places have been over 8 ft. thick. Only ore extracted in course of development has been shipped. In the Ely Valley prospecting cross-cuts are being pushed on the 300-ft. level to the northeast and southwest. Four known veins are expected to be cut at this level. Considerable first-class ore has been developed, running up to \$10 per ton in gold, 30 oz. silver, and 20% lead. It has not been the policy of the company to ship, the officers believing that lead and silver will soon advance in price. The Boston & Pioche has been steadily sinking its main shaft on the old Yuba East. A cross-cut from this shaft on the 800-ft. level recently cut the ore, which was found to be of the same high character as that found in the upper levels. To the north of the Prince Consolidated lie the Pioche King, the Golden Prince, and the Gold and Silver Prince. Each hopes to catch the Prince orebodies. The two former are already equipped with machinery for hoisting and air-compression, and the latter has its machinery on the ground. The Pioche King was organized by John A. Kirby, the well known mine-manager of Utah and Nevada, and one of the largest owners in Nevada Hills.

One of the most important factors bearing upon the future of this section is the increasing assurance of a railroad to Ely. The purchase by the Cole-Ryan combination of control in the Groux, and the financing of the Goldfield-Ely railroad, tend to confirm the statement so often heard of late that Ely is to be made one of the great smelting points in the West. Ely must have Pioche ores for fluxes, if much smelting is to be done. It is stated that the road

is to be built south from Ely and is to be closely allied with the Ely Northern. This would give Pioche a competing line to Salt Lake City. Other information is to the effect that the Salt Lake line is anxiously watching the situation, with a view to building from Pioche to Ely. This would give Los Angeles a line to Ely by way of Pioche, as well as Goldfield, and would give Ely a competing line to Salt Lake City.

WHITE HORSE, YUKON TERRITORY.

Cold Winter.—Burwash Creek.—Copper King.—Valerie. — Railway and Smelter Changes.—Conrad Consolidated.

Owing to the present low price of copper, little work has been done during the past winter in the White Horse district; the severe winter has also had its effect. Beginning soon after Christmas, the weather settled in cold and remained so until well along in February. It is claimed that during this time the average degree of cold was 30 below zero. In spite of this cold weather, a pay-streak was discovered, and is reported to have been traced about 4 miles on Burwash creek, a tributary of the Klunian river, 100 miles west of White Horse. The pay was found in an old channel of the creek, the bedrock of which is slightly above that of the present bed. Pannings average from 3 to 4c. per pan, or about \$2 to the bucket. For a depth of 5 ft. above bedrock, the pannings on bedrock are said to be considerably better. The pay is believed to be at least 60 ft. wide. If future work proves these conditions, the creek will become a great producer; it is however too soon to give any accurate estimate of its real worth. Among the most promising copper properties in the immediate vicinity of White Horse, is the Copper King. On this property work has been carried on all winter, and some 400 tons of ore have been shipped to the Tyee smelter on Vancouver Island. This ore is said to have run 15% in copper and 2½ oz. in silver, with a small amount of gold. The property belongs to J. C. Whitney and W. C. Pedlar, of White Horse, and to the estates of W. P. Granger and John C. McIntire. At the present time Thomas Guffy of Pittsburgh, and associates, have a bond on the property. Harry Baxter is the local manager. His address is White Horse, Y. T. Much is expected of this property in the future.

On the Valerie, considerable development work has been under way this winter, and a good body of ore has been exposed, which is said to run 15% copper. There is a large amount of possible ore in this mine. It is owned by A. B. Palmer of Vancouver, B. C. A spur seven miles long has been built by the White Pass R. R. Co. This track leaves the main line a little south of White Horse, and reaches most of the properties of note. It is understood that a revision of rates is being planned which when complete will permit most of the mines to ship their ore to the smelter. The railroad company has also erected large ore-bins equipped with chutes at Skagway. This will facilitate the loading of the vessels that carry the ore to the smelter. These improvements have cost the White Pass R. R. Co. fully half a million dollars. There is talk of the Tyee Smelting Co. putting up a plant at some point near White Horse.

The Conrad Consolidated Mines is on Windy Arm, which is a neck of Lake Tagish, Y. T., some 25 miles east of Caribou, on the White Pass railway. J. H. Conrad is president of this company. Work has been going all winter on the Venus claim, where a 50-ton concentrating plant has lately been completed. Good results have been obtained. The concentrates are shipped to the smelter for reduction. The property is now on a successful basis, due in a great measure to W. H. Vance, the superintendent, whose address is Windy Arm, Y. T. The Big Thing is another property on Windy Arm, in which J. H. Conrad and some associates from Toronto are interested. Last winter a body of high-grade ore was struck. It is reported worth \$40 per ton gold, besides having a high silver content. The strike has caused a good deal of excitement. At present 100 tons of this ore is at Caribou, ready for shipment to the smelter. W. H. Vance has charge of this property.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Coal-fired furnaces yield the highest heat-efficiency when the stoking is done at frequent intervals, using light charges.

California magnesite is equal if not superior to the Hungarian in quality. Owing, however, to its occurring here in smaller veins, to the higher wages prevailing, and to the long railway haul, the local material does not reach the Eastern market. There is no tariff on magnesite.

Zinc-dust is composed of metallic zinc coated by a film of oxide. It forms readily by dilution of volatilized zinc, and condenses as a powder in particles so small that they cannot coalesce to form a liquid. Formerly a source of loss to zinc smelters, it has become a valuable by-product.

Ochre is prepared for the market by fine-grinding and sizing. Occasionally it is given a light roast to perfect the color. It is sold mainly to paint grinders and to manufacturers of linoleum and oil-cloth. Approximately 16,000 tons per year are now marketed in the United States, at an average price of \$10.

Pitchstone is a variety of obsidian in which the rock is dull and opaque, appearing glassy only on thin edges. It resembles an over-limed iron-furnace slag. It often possesses a resinous appearance, whence its name. It varies in color from black to gray, and is sometimes red, brown, and not infrequently green. It contains from 5 to 6% moisture.

Boiler-waters are often softened by the use of fats, which combine with the lime and magnesia to form soapy compounds. It should not be forgotten that these attach themselves to the plates and, having a lower conductivity than calcium sulphate, increase the danger of over-heating and explosion. When petroleum is used compounds having corrosive properties are formed.

Miarolitic structure is a term applied to open spaces or vugs in crystalline rocks, usually drusy from the development of crystals free from interference. The open spaces are the product of contraction during the solidification of a rock from the condition of a fused magma. Miarolitic cavities must not be confounded with geodes and drusy cavities in which the crystals have been subsequently deposited from solution.

Assay-ton is the name given to a weight of 29,166 gm., which is $\frac{1}{1000}$ of the number of troy ounces in a ton, of 2000 lb. If a sample of 1 assay ton is taken and the resulting bead weighed in milligrams, each milligram represents 1 oz. per ton. Should it be required to weigh the pulp in grams, the following principle will be found useful: 29,166 oz. troy is equivalent to 1 ton. The value of 1 oz. pure gold is

\$20.67. Therefore 29,166 oz., or 1 ton, equals \$602,861. If 100 gm. is taken for a sample and the bead weighed in milligrams, then from the proportion 1 mg. : 100,000 mg. (100 gm.) = x : \$602,861, each milligram represents \$6 per ton.

Garnet is frequently found in the contact zones between eruptive and sedimentary rocks. In such situations it is evidence of contact metamorphism, and sometimes accompanies deposits of copper. In New York, Pennsylvania, and North Carolina it is quarried and mined for use as an abrasive. For such purposes it is worth approximately \$30 per ton cleaned and delivered in New York. About 7000 tons per year are marketed.

One hundred per cent dynamite is a misnomer, and a most crude one at that, for blasting gelatine, which is a mixture made by dissolving guncotton in nitroglycerine. The term erroneously applied to this explosive would, if properly used, mean nitroglycerine alone. Dynamites are graded according to the amount of nitroglycerine absorbed in the dope, expressed in percentages. The highest grade manufactured for railroad transport is 60%, but 70% dynamite is made for shipment by sea.

Phosphor-bronze is employed in situations where resistance to corrosion, coupled with great strength, is required, as in pumps for mine-waters. It is composed of copper, tin, and phosphor-tin, the latter being an alloy containing 5% phosphorus. The phosphorus is added to reduce the metallic oxides, thus toughening the metal. A good acid-resisting phosphor-bronze consists of copper 90, tin 9.8, and phosphorus 0.2%. The tensile strength of the alloy is from 40,000 to 50,000 lb. per square inch.

Lead-covered conductors for electricity are the best in all wet situations, and should be used in shafts. The lead covering is a protection against chemical action and mechanical injury. It is further advantageous to protect the lead-sheathed cable with wooden cleats, or to box it to prevent accident. The branch cables at the various levels are connected by ordinary branch-joints. High-grade rubber-insulated cable may be used in metal mines, in which case extra precautions against injury should be taken. Boxing the cable will usually suffice.

Iron-ore reserves have been variously estimated by different statisticians, and have given rise to controversy, but the essential significance of the estimates, in which there is general agreement, is that the large reserves of metallic iron in the ore credited to Germany and Great Britain are actually unavailable at present, on account of the competition from high-grade reserves in America, Spain, and Sweden. The American ores range from 45 to 67% Fe, and those of Spain from 40 to 56. The attack for commercial uses is upon the high-grade deposits first. Estimates of the world's supply of iron will have more significance after the depletion of the reserves in America has brought her to the condition of England and Germany.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Mechanical Elevator in Hydraulic Mining.

The Editor:

Sir—In the MINING AND SCIENTIFIC PRESS of April 10 you mention a mechanical elevator made for George H. Evans of the Gold Pan Mining Co. at this place. I wish to state that there was such a mechanical elevator made and shipped here, but it was never installed. I believe, and have always believed, that a mechanical elevator would be the proper machinery to work such ground as the Gold Pan, or any that has large boulders to any great extent. The use of a mechanical elevator will allow the bedrock to be cleaned up while dry.

Eight-Hour Legislation.

The Editor:

Sir—The article published in your issue of April 17 upon 'Eight-Hour Legislation' is admirably written and carefully thought out; but it does not mention an important feature of the Utah case, namely, that by the constitution of that State it is specially enjoined upon the legislature as one of its duties to pass laws to provide for the health and safety of employees in factories, smelters, and mines, and it is therefore not to be wondered that, in the case you refer to of *Holden v. Hardy*, the law was held to be valid under the Utah constitution.

Also you do not refer to the case of Colorado, in which it was finally decided that the eight-hour law for mines and smelters violated the constitution of that State, which constitution inhibits class-legislation. I need not cite the many provisos in the constitution of California, such as Art. 1, Sec. 1, 11, 13, 21; and Art. 12, Sec. 25, which protect citizens against interference with their liberty of contract or against class and discriminatory legislation; but in view of these facts it would not appear that the Utah case can be held as a precedent, and I suggest there is reason to believe that the eight-hour law known as Assembly Bill No. 445 might be declared to be opposed to the constitution of California.

Colombian Health Conditions.

The Editor:

Sir—In an article on 'Economic Conditions in Colombia' in your issue of April 17, F. Lynwood Garrison gives as the seventh class of malarial fevers treated by the physicians of the Canal Zone during the year 1898, "Hemoglobinuric fever—discharged 29 died 11," and as the fifth in his classification he names "pernicious malaria, the deadly blackwater fever, known scientifically as *laverania malariae*." He

further writes, "I have heard of some cases of the deadly 'blackwater fever' in Jamaica, but none in Panama or Colombia, although, like the beri-beri, if once introduced it may be difficult to stamp out under favorable conditions for its propagation. The blackwater fever is common in Africa, just as beri-beri is in China and Japan."

In Africa the blackwater fever, sometimes also called hematuric fever or hematuria, is the hemoglobinuric fever (hemoglobin in the urine). It may be a trifle strong to speak of it being 'common' there, yet in all the region north of the Rand it certainly is sufficiently prevalent to make it a thing to be dreaded, and the proportion of deaths in cases treated at Panama, about 1 in 3, is similar to that where patients are cared for in African hospitals. Out in the bush, away from good nursing, the percentage of fatalities is much larger, and in any tropical country where this dreaded malady exists it should, and must, be of serious consideration for men going to prospect or mine.

The disease is so little understood that it is difficult to obtain much accurate information about it. In his book, 'The Truth About the Congo,' Prof. Frederick Starr says: "The disadvantage of this constant dosing with quinine is the danger of the dreaded hematuric fever. This dread disease rarely attacks a person until he has been a year in the Congo. It is commonly attributed to the system being loaded up with quinine. The instant that its symptoms develop the order to cease taking quinine is issued. Among the European population of the Congo, hematuric fever is regularly expected to have a fatal issue. It is more than probable that the use of wines, beers, and liquors predisposes the system to fatal result. Plenty of missionaries die of hematuric fever also, but the appearance of the disease among them by no means produces the panic that it does among Continentals. Perhaps one in five or six cases will die, two of the remainder will flee to Europe, the other three may recover; but the disease is no trifling matter, and must be seriously taken."

The idea that the continuous taking of quinine causes 'blackwater' is prevalent in Africa, but the weight of British authority is to the contrary. It is also often claimed to result from frequent attacks of malaria, but the better opinion leans to the belief that frequent attacks merely weaken the system so as to make resistance to hematuria feeble. It is also known that the disease is not likely to come until after a year or more has been spent in the country, but instances are not infrequent where newcomers have been victims. It afflicts the young and vigorous (and that, too, sometimes when they are feeling 'extra fit'), rather than those of more mature years. Quinine appears to aggravate the malady, and must not be given. "Favorable conditions for its propagation" are unknown, as it is neither contagious nor epidemic; it is rather endemic, and appears to come sometimes in waves over a district. It occurs in depressed or basin areas at high altitudes as frequently as in low-lying regions. As the cause of it is unknown, no specific has yet been found.

In malarial fever there is a somewhat gradual

breaking up of the red corpuscles of the blood, in the manner described by Mr. Garrison. Black-water fever comes from the rapid destruction of these red corpuscles, and as the system endeavors to cast off the dead discs in every way, it is essential to keep all passages open, more especially the kidneys, which may become clogged, leading to agonizing and fatal results. It is also of the utmost importance to prevent collapse, and the best stimulant, practically the only one that the stomach will retain, is champagne, administered slowly by teaspoonfuls. All well-equipped parties traveling in Central Africa carry champagne as a precious medicine for this purpose, with prayers that it may never have to be used.

What Is an Ore?

The Editor:

Sir—If you insist on publishing articles provoking discussion, you must suffer the penalty. Concerning 'What Is an Ore?' in your issue of March 20, I must say, in the first place, 'ore' is a term which properly has no 'mineralogical sense'. It is purely a commercial term, and therefore affects only the miner and the metallurgist. Generally speaking, it would seem best to define an ore as any natural earthy product containing free or combined metal or metals which can be mined and treated at a profit for any metal or metals therein. It cannot be ore to the miner and waste to the metallurgist, or vice versa, since its definition as 'ore' is a function of any profit derivable after deducting the total cost of handling.

F. C. SMITH.

Sault Ste. Marie, Ontario, April 17.

Protection of Investors.

The Editor:

Sir—As the discussion of this subject progresses, under the auspices of the Mining and Metallurgical Society of America, the chief elements of danger have become well defined. We have an expression of opinion as to items of information to be given by mining companies for the guidance of stockholders. These are, in brief, the commercial history of the enterprise, its present financial condition, a detailed statement of ore-reserves, an estimate of the probable life of the mine, and a valuation of the property.

The classification of ore-reserves has been freely discussed and generally agreed upon. To estimate the life of a property is, admittedly, a matter of greater complexity. To calculate the value of ore available and blocked for stoping is not difficult. To determine the time necessary to exhaust orebodies already blocked is relatively simple. To successfully estimate the possibilities of undeveloped ore requires wide geological experience and discriminating judgment. To form a safe forecast of ore as yet undiscovered is always difficult, and in some cases beyond the range of human power. Yet all four of these operations are involved in estimating the life and value of a mine.

In an established district, where some mines have

already attained substantial depth and many of the more important factors are known, and especially where the ore has some regularity of occurrence, one may, with fair hope of accuracy, base an estimate of the life of a new mine on facts developed in a neighboring property. But in a newly opened area of mineralization, a pioneer mine is often wholly in the prospect stage with regard to its possibilities beyond the ore actually blocked, and one of its assets is the geologic promise of continuous or extensive mineralization. The extent to which this must remain an unknown quantity depends upon the amount of money available for development in advance of actual mining.

While we agree on the need of protection for investors, and of information tending to achieve this end, there seems to be a disposition on the part of some contributors to consider only the protection of investors in producing mines. It is obvious that a mine is rarely productive at the start. It normally has to pass through the prospect stage before reserves can be developed, and sometimes the reserves become exhausted and the mine reverts to the condition of a prospect; so it seems as if we were avoiding the discussion of mine management in the prospect stage, when many properties are temporarily injured by bad work, and offering help to investors only when a property has weathered the storm of uncertainty and cast anchor in the harbor of ore blocked. Nearly all mines that are now producing had stockholders while they were being tested as prospects, and stockholders in prospects are often quite respectable people and deserve all the help they can get.

Since the mining industry would come to an end if development of prospects should cease, I think it is wrong to confine the discussion to the administration of productive mines and to leave the public to conclude that prospects are in any sense illegitimate. It would be quite as logical to continuously refer in terms of contempt to children. Just as 'the child is father to the man', so is the prospect father to the mine. The mortality among prospects is probably no greater than among children, and failures in mining are no greater than in ordinary business pursuits, where only 2% achieve success. Further, the salesman's tricks used in disposing of mining stock are used in selling many other commodities.

We want to make the public acquainted with the tricks of unscrupulous people, but we do not want them to imagine that any of the different stages of the mining industry are not proper channels for financial venture if in honest and competent hands. There will always be persons who cannot afford to invest money in any business which involves risk: for such persons there are numerous investments which yield a small but safe income. On the other hand, there will always be persons, in active business life, who make more than they need for current expenses and like the excitement of putting money into new ventures. For such persons mining, under competent technical advice, is as safe an outlet for surplus funds as the common activity of real estate speculation, or as some branches of agriculture, which in many portions of the country are well

known to be a gamble against weather and climate, with further difficulties in connection with transportation and manipulated markets.

As I view the situation, the difficulty is not so much with the risk in mining as with the ways in which money may be raised in the name of mining, and with the way in which it is spent by unscrupulous persons. Many promoters raise money on a mining enterprise, not to benefit the stockholders, but to pay themselves a salary and to absorb a part of the money for expenses. But the same thing is done in other kinds of business.

When a mine has reached the degree of development which proves the existence of a substantial ore-body, its owners are usually anxious to raise money for equipment, and sometimes are willing to sell and enjoy a moderate reward for their labor and risk. If it happen that they have not the necessary financial connections to raise money through a syndicate or close corporation, the promoter comes in to do the work of raising the needed money. The mine may have a half million dollars' worth of ore blocked, and perhaps \$200,000 may be needed to erect a reduction plant and to provide working capital. The promoter, if he is unscrupulous, forms a corporation with a capital of from one to ten millions, takes 40 to 60% of the stock for promotion profits and expenses, and sells a certain amount of the remainder at a fraction of its par value in order to raise the necessary cash for the mine equipment. He makes his profit by selling his personal stock. His theory is that stock offered at a small fraction of its face value seems a better bargain to the average purchaser, and so a large amount of stock is sold to raise a relatively small amount of money. Sometimes stock is sold under pretense of underwriting by some trust company. For example, a brokerage firm in the East offers to sell on commission any mining stock entrusted to it, provided the stock be underwritten by a certain trust company in the West. The underwriting company is usually willing to underwrite anything for a consideration, and its guarantee is often flimsy, and essentially worthless as a protection to the purchaser of the stock.

In conclusion it must be said that frenzied finance, over-capitalization, and serious financial blunders are not confined to mining companies, and that neither the mining industry nor mining engineers should assume or be allowed to bear a stigma which is undeserved. Mining, properly handled, is as safe as any other commercial industry.

F. J. H. MERRILL.

Nogales, Arizona, April 17.

The Engineer as a Financier.

The Editor:

Sir—Protection of investors and the function of the engineer as a financier are so closely connected that it is surprising that no one has correlated the two. With the engineer acting also as a financier, there can be no protection to investors, for the financier is looking toward his own gain at the expense of the investors. An engineer who deals in the stocks of any corporation with which he is connected, or

who accepts the promise of a fee should his report be favorable and a sale be made, is, in my opinion, violating professional etiquette. But we are considering mining, and particularly gold mining, in which there is no professional etiquette, for the mining engineer has no legal status. All that seems to be required is a pair of high boots and a suit of corduroys, and as for the superintendent, his qualifications are to be a friend or relative of the promoter, or the president of the company. This is not said in jest; it is a fact of frequent observation.

How can the investor be protected by law unless his agents have some lawful standing. Because one can cure a cold or bind a wound is no sufficient qualification for a doctor. Because one can interpret commercial or common law, does not make one a lawyer; but anyone who leases, promotes, finances, or mismanages a mine, may call himself a mining engineer and is liable to be taken at his own rating.

One of your correspondents some time ago remarked that without the wild-catter, the promoter, and the fake mining engineer, large tracts of country now occupied and inhabited would still be dreary wastes. Perhaps he was right, but the question is, has or has not the time come for a different order of doing business? If so, how can it be done? It would be useless to fix by legislation who is a mining engineer, for this has never been attempted, although in Europe it is generally understood that a man must have received a technical education in a mining school. In this country it is otherwise. The legislature, however, could pass a law defining the qualifications of a mine superintendent or a mine manager, and make compulsory the issuing of definite reports, and compel the company's officials to post these reports in a conspicuous place in 'their office', or if the office is not in the State, then at the shaft or office at the mine, so that it would be public property. Superintendents as a rule give all necessary data to the office, but the officials for their own purposes do not give out these reports. If the managers were compelled to give certain facts, and if the officials were compelled to make them public, the investor would be well protected. It might be a good idea to have monthly reports registered with the County Recorder.

Some years ago I applied, in answer to an advertisement for desk-room in a lawyer's office. I stated that I was a mining engineer. I was politely shown the door with the remark that "to have a mining engineer in my office would ruin my business." And that from a lawyer!

Some of us younger members of the profession have had a rather rude awakening lately. Our alma mater had drilled into us the idea of being a man first, and above all things to play the game of life fair. We now see those whom we had looked upon as being at the top of the profession acting as nothing but 'money grubbers'. We see them lending their names to make a market value for stocks. What are we to do? Play the game fair! If integrity does not lead to the top, then peg away in the mill, the mine, or the cyanide plant, and still remain a man.

ALGERNON DEL MAR.

South Pasadena, California, April 10.

CYANIDATION AT MERCUR, UTAH.

Written for the MINING AND SCIENTIFIC PRESS
By LEROY A. PALMER.

The first cyanide mill in the Western Hemisphere was built at the Mercur mine, in Utah. The Consolidated Mercur, successor to the original company, built what was for a number of years the largest straight cyanide plant in the world. The development of the process for this company forms an interesting chapter in this branch of metallurgy, and although larger plants have since been erected, many textbooks still devote space to Mercur practice as exemplifying the most successful method of treating certain classes of ores.

The ore in this district is porous and friable, prone to slime excessively, and it causes much trouble on this account. In fact, the first attempts at cyaniding were a flat failure, because, when crushed to the size supposed to be necessary, the pulp formed a thick slimy mud which the solutions absolutely refused to penetrate. Slime has always been troublesome. Recently an extensive slime-plant, embodying many new features, has been installed, and has brought the problem nearer to a satisfactory solution than hitherto. The mine furnishes two classes of ore, one oxidized, and the other base, owing to the presence of sulphur and arsenic. These two classes are broken separately, and dumped into different pockets at the Golden Gate incline, where they are hoisted to the crude-ore bins in two 4-ton skips, working in balance. These bins are of steel, well braced by steel beams and columns.

The progress of the base ore through the mill is as follows: Passing over a grizzly the oversize goes to a No. 6 Gates gyratory crusher, which reduces it to pieces that will pass a 3-in. ring, and discharges to the crushed-ore bin beneath. To effect distribution in the bin the crusher-discharge can be turned into a bucket elevator, dumping to a chute that sends it to the farther end of the bin. In the front of the crushed-ore bin are seven gates, through which the ore discharges into a chute leading to a large hopper set over an 18-in. inclined belt-conveyor, which carries the ore to a set of 14 by 36-in. Allis-Chalmers A (Gates) rolls. These rolls discharge to a second set of the same size, and those in turn to a third set, 14 by 24 in. The third set discharges to the No. 1 elevator, which dumps to a wire-cloth trommel having three meshes to the inch, thus allowing a free opening of about $\frac{1}{4}$ in. The oversize from this trommel goes to a second, with openings three one way by one the other in each square inch, giving a free opening about $\frac{1}{4}$ by $\frac{7}{8}$ in. The oversize from this trommel goes to a fourth set of rolls, 14 by 24 in., discharging to the No. 2 elevator, which dumps to the bin without screening. In the chute to each set of rolls is a screen of the same mesh as the second trommel. These take out the undersize, which goes to the No. 2 elevator. Owing to the nature of the ore, crushing is done dry. All other elevators are 14 in. with 6 by 14-in. cups, spaced 20 in. from centre to centre. The bins are all of steel, well reinforced by 9-in. I-beams placed both vertically and horizontally. Below the

bins are three floors containing the roasters, five in number, three of the Jackling type, one Brown, and one Holthoff, each having a capacity of 70 tons. The crushed ore discharges through the steel gates to a conveyor running in front of the bins, which in turn discharges to a conveyor running at right angles and over the feed end of the furnaces, which are arranged two on a floor, except on the second floor, where there is only one. The base ore is discharged to a large hopper, from which it is fed to the furnace by plunger-feeders. The Jackling furnace, designed by D. C. Jackling, who is now manager for the Utah Copper Co., is the most successful of the three types, and embodies practically the same principles as the others. The furnace is of brick, with fire-brick lining, 100 ft. long, 16 ft. wide, and 3 ft. high at the sides, with an arched roof rising 8 in. An endless chain carries 6 beams with 22 scrapers. The scrapers keep the ore rabbled, and at the same time draw it slowly forward. On each side are two coal-fed fire-boxes in which a blast from a fan aids in maintaining the desired heat, and a steam-jet directs the flame downward upon the ore. The sides are well provided with cast-iron doors, permitting ready access to any part. By the time the ore has been dragged the length of the hearth, which is 10 ft., the sulphur and arsenic are all expelled, and the roasted ore is discharged, and is picked up by an elevator consisting of beams each of which carries five cups. This dumps it on the cooling platform, about one foot above the furnace. Here it is slowly scraped back, being turned and exposed to the air in the process, until just before it reaches the end at which it is fed it passes under a spray of water, and is discharged by a screw to the belts that carry it to the bin above the leaching floor. For the last fiscal year the cost of roasting, including maintenance and repairs, was \$1.217 per ton. As will be seen later, this figure was made under disadvantages, including a fire which destroyed a large amount of coal, all of which was charged to the roasting department.

From the crude-ore bins on the oxidized side of the mill, the ore passes over a grizzly and through a No. 6 Gates crusher, reducing it to 3-in. size, and discharging to the crushed-ore bins. From these, 7 gates discharge to a hopper over an 18-in. horizontal conveyor which dumps to a set of 14 by 36-in. Allis-Chalmers A rolls, the product from which goes to a similar set of 14 by 24-in. rolls, discharging to the No. 1 elevator. This elevator dumps to a 3-mesh trommel, which sends the oversize and undersize to separate bins. In each roll-chute is a screen similar to those used on the base-ore side, and the undersize from these screens goes to the No. 2 elevator to be dumped with the fine ore. The coarser ore contains chunks as large as 1 in., but they are so porous that the solutions permeate them without difficulty, and it has been found that fully as good an extraction is made on these sizes as on the material more finely crushed. This coarse ore, ranging in size from $\frac{1}{4}$ to 1 in., is discharged through the gates to a conveyor parallel to the bin, which dumps to another running to a chute, terminating at a bin beside that which receives the roasted base ore. On the leaching floor

are 26 rectangular steel vats, 48 by 24 by 4 ft., with the usual cocoa matting and canvas filter-bottoms, and 8 circular discharge-openings, 12 in. diam., with drop doors underneath over a series of four parallel tramway tracks. The three stock-solution tanks set on the next floor above the vats give a good pressure for forcing solution from below, if necessary. Each stock-tank is circular, of steel, 20 ft. diam. by 12 ft. deep.

The leaching vats are charged by tramming from the bins, each vat being filled to a depth of 2 ft. with the coarse oxidized ore, and the remaining 2 ft. with the roasted fine. Thus the coarse ore forms a filter for the fine, allowing the solutions to percolate thoroughly without packing. The vat being filled, 1500 lb. of lime is sprinkled over the top, and a 2-lb. KCy solution is turned on from below. When this has covered the top it stands for a few hours before being drawn off. The usual practice of aerating is

the filtered solution from which runs to the sump and is pumped back to the weak-solution stock-tank. The zinc consumption is $\frac{1}{3}$ lb. per ton of ore. Working beside the filter-presses is a standard type of zinc-box, 17 by $2\frac{1}{2}$ by 3 ft., divided into 7 compartments. This was installed as an experiment, and has been so successful that the management is contemplating changing to this method of precipitation. The weak gold-solution is collected in an 18 by 12-ft. circular steel tank, and without precipitating the gold it is pumped back to the strong-solution stock-tank, and cyanide is added to bring it up to a strength of 2 lb. per ton. Two 5-in. geared Gould rotary pumps handle the solutions.

The slime-system is as follows: All oxidized ore that passes through the 3-mesh trommels goes into its own bin, and is drawn through the gates to be mixed at once with strong cyanide solution. This washes it to the separators and classifiers. The first

Consolidated Mercur Mill.

found to be a disadvantage, causing the ore to pack, and preventing the free circulation of the solutions. As fast as the solution is drawn from the bottom, more is run on the top, so as to keep the ore continually covered at a uniform depth. Two days after the strong solution is first turned on it is replaced by the weak wash (1 to $1\frac{1}{2}$ lb. KCy per ton), and the charge is treated with this for three days. This is followed by a two days' treatment with wash-water, and the tanks are then discharged by shoveling through the doors to tram-cars, which are hauled to the dump by horses. The consumption of lime is 6.85 lb. and of cyanide 0.7 lb. per ton of ore treated. The strong solution, when drawn from the leaching vat, runs to an 18 by 12-ft. circular steel tank, from which it is pumped to three 14 by 8-ft. circular steel tanks, where zinc fume is added. The pumping serves to agitate the solution, and this is further accomplished by air under pressure from a simple 10 by 14-in. motor-driven Ingersoll-Sergeant compressor placed on the sump floor. The zinc-gold solution is drawn off to 11 Johnson filter presses, each 7 $\frac{1}{2}$ by 2 by 2 ft.,

stage is to pass it successively through two so-called 'mixer-separators'. Each of these consists of a box 20 by 3 by 3 ft., having a grade of one inch per foot. In the box is a longitudinal shaft, having two blades set every 6 in., similar to the blades of a ship's propeller. This shaft slowly revolves, working the ore upward as a screw-conveyor, while the solution tends to wash it toward the end of the box. The coarser particles offer sufficient resistance to the current to work out at the head of the box by the action of the screw, but the finer wash out of the opposite end to a second similar device, where the process is repeated. The separation of the coarse from the fine and the mixing of the latter with solution, gives the device its name. The tailing from the second 'mixer-separator' goes to a cone, and the overflow from this goes to the slime-tanks, and the settling discharges to two Dorr classifiers. The Dorr classifier is a box with an inclined bottom 15 ft. long, 2 ft. deep, and $4\frac{1}{2}$ ft. wide at the upper by 4 ft. wide at the lower end. The grade is the same as for the 'mixer-separators'. Lengthwise in each box are two shafts, each carrying

at intervals of 5 in. a toothed scraper-blade, 3 in. deep. These scrapers are actuated by a crank, with 10-in. swing, connected to each shaft. The scrapers are drawn forward along the bottom, then raised and pushed back 10 in., to be drawn forward on the bottom again. The pulp is fed in about one-third of the length above the tailing-discharge, and is subjected to an action similar to that on the 'mixer-separators', that is, the heavier is scraped out at the head and the lighter washed out at the tailing-end. A treatment of the tailing on a second classifier completes the separation of sand from slime. The heads from all the separators and classifiers run direct to a leaching vat, where they are treated as described above. The tailing from the last classifier runs in solution to three circular steel vats 30 by 8 ft. In each vat is a decanter, consisting of a perforated 5-in. horizontal pipe 6 ft. long. This is connected to two vertical pipes, passing through the bottom of the tank. This decanter is set on the opposite side of the tank from the feed-inflow, so that the slime may have an opportunity to settle and leave the decanted solution clean. Part of this decanted solution is re-used by mixing with the ore, and part is run to the precipitating room to be treated with zinc-fume. Agitation of the slime is not attempted, and it is found that the gold goes into solution in 24 hours. The tanks were originally provided with agitators, which are now used to scrape the bottoms when discharged. When a tank has been filled with slime a centrifugal pump transfers the contents to a fourth tank of the same size, where the pulp is thickened and then run to a circular steel sump-tank 15 by 8 ft. A duplex beam air-pump discharges the contents of the sump-tank to three wooden tanks, 10 by 12 ft., from which the pulp runs by gravity to the filter-room. Here are four square steel tanks, 8 by 8 by 7 ft., with a cone-bottom 4 ft. deep, equipped with vertical stationary filters. Agitation is accomplished by pumping from the bottom and discharging at the top, thus allowing all of the solution to reach the filtering surfaces. The filtered solution flows to the precipitating room, and when a tank is full of slime a gate-valve is opened in the bottom, the contents discharged, and the filters washed with a hose. The zinc-slime from the precipitating room is taken to the refinery, where the zinc is dissolved in sulphuric acid. The filtrate is roasted in a furnace with three 30 by 60-in. muffles, fluxed, usually with borax glass only, and charged into the melting furnace. This furnace is double, each side having a capacity of 60 lb. of the product. The roasting is done with coal as fuel, while for melting crude oil is used.

The mill is equipped with a machine shop having the usual complement of tools for a large plant, and a foundry where all but the largest castings are made. The latter has a circular 36-in. furnace, with five 2½-in. tuyeres. Power is furnished by the Teluride Power Co., whose lines enter the camp at a tension of 40,000 volts and are stepped down to 5000 volts at the sub-station and to 220 volts at a transformer station at the mill. The water is pumped from Ophir canyon, seven miles distant, by the Gold Belt Water Company.

The figures which the management publishes concerning operating expenses during the last fiscal year are doubtless a better criterion as to present cost of production than an estimate that could be made by one not closely in touch with the operations, but it is hardly fair to judge by the year in question, because during that time an unusual amount of development was done, including opening some old stopes directly under the immense mill-dumps. Also, for a large part of the time production was made by only a fraction of the plant. During the period mentioned the average value in the ore was \$3.77, all in gold, of which \$2.85 was recovered. Mining costs averaged \$1.65 per ton, and milling costs \$1.27, or a total of \$2.92. A loss of 7c. per ton of ore treated was therefore sustained. For the current year it is hoped to bring the costs to the point previously reached, namely \$1.41 for mining and \$1.07 for milling, a total of \$2.48. These figures include all executive and administrative expenses. The slime-plant, as installed, was experimental, and its capacity is not up to that of the mill, which has tended to keep the tailing up to the high figure of 92c. During the time that the mill handled a tonnage in proportion to the slime-plant, the tailing averaged only 46c. per ton. A feature that has caused much perplexity, and which is being experimented upon, is that the slime from the roasted base ore is not amenable to the same treatment as that from the oxidized ore.

About 4½ miles below Mercur, at Manning, is the mill of the Manning Leasing Co., working on the dumps of the old Mercur mill. Here are 700,000 tons of tailing, of an average value of over \$2 per ton. The method used is that of the Holderman Process Co. of Salt Lake City. Near the mill a tunnel for tram-cars has been driven into the dump, and bins constructed. Slip-scrapers drag the ore and dump it into a hopper leading to this bin, from which it is trammed to the mill-bins by hand. From these it is fed to two 6-ft. Chilean mills, one Akron, and one Monadnock, and is crushed in solution. Each mill has a capacity of 120 tons. The ore is crushed so that 80% passes a 60-mesh and the remainder a 40-mesh screen. Without separation of sand from slime the pulp is run to the first tier of vats, of which there are 18, each 18 by 6 by 4 ft., with a bottom sloping from back to front with a pitch of 2 in. per foot. The tanks used in the Holderman process have filters on the bottom, sides, and ends, and 34 suspended filters in each 18-ft. tank. These suspended filters are merely canvas sacks over slotted pipes through which the solution can be drawn off. The use of these gives a filtering surface to every 6 in. of length in the tank, and allows the solutions to quickly reach every ore particle. When the process was first tried, agitation was used, but this has proved unnecessary, and has been abandoned.

In the front of each tank, and flush with the bottom, are three discharge-gates with launders running to the second tier of tanks. After treating in the first tank with a solution of 1 lb. excess-alkalinity per ton, the pulp is flushed with clear water to the second tank, the water with the solution left in the pulp, making the proper strength of weak solution.

In the second tier are six tanks, 18 by 6 by 7 ft., with the 34 filters submerged 2 ft. below the surface. The entire time for percolating and leaching is 18 to 24 hours, after which the vats are flushed out. Both strong and weak solutions are collected in a sump, and are pumped to the gold-solution tank at the top of the mill by a centrifugal pump. This tank is 16 ft. diam., with 17 suspended filters to prevent slime getting into the zinc-boxes in case a filter in one of the leaching vats should break. The solution is brought to standard in this tank, and is passed through a zinc-box 18 by 2½ ft. The precipitation is so nearly perfect that the tailing from the zinc-box does not show even a trace of gold. This precipitation takes place in the first three compartments. For the present the precipitate is being shipped, but a refinery is to be built in a few months. The extraction of the soluble values is 97%, with a consumption of 0.35 lb.

VANADIUM DEPOSITS IN PERU.

By D. FOSTER HEWETT.

*The two Peruvian vanadium districts are situated in the Department of Junin; Yauli, the less important being in the Province of Tarma, and Quisque (Minasragra) in the Province of Pasco. The Peruvian Central railroad passes through the first, and the second is accessible by horseback from Fundición, on the Cerro de Paseo railroad. A description of the Yauli district will precede that of the more important Quisque district, for the reason that the first throws light on the second. The Quisque deposit was discovered while I was examining the Yauli district.

Though not announced until 1894, the presence of vanadium in the so-called 'anthracite' (asphaltite) of the Yauli region was known in 1892. Theretofore,

Filter-Presses and Solution Sump, Mercur Mill

KCy per ton, and a zinc expense of 1¾c. The Chilean mills are driven respectively by 35 and 50-hp. motors, the latter driving also a centrifugal pump delivering solution from the zinc-boxes to the stock-solution tank. One 5-hp. motor runs a centrifugal pump elevating solution from the sump to the gold-solution tank, and one 5-hp. motor drives a rotary pump for sluicing. Power is taken from the sub-station at Mercur. It is transmitted to Manning at 5000 volts and transformed at the mill to 440 volts. Springs furnish about 115 tons of water (30,000 gal.) per day. Each ton of ore requires 300 to 500 lb. of water.

The plant is designed for 240 tons per diem, and when run at full capacity, treatment costs can be brought down to 60c. per ton. During the winter, owing to the fact that the dump is frozen, and that the mill-bins have not a sufficient storage-capacity to provide against contingencies, only about 140 tons are being treated, at a cost of 70c. per ton. For assistance in obtaining data for the above description, the writer wishes to acknowledge indebtedness to George Dern and Tom Fergusson, managers of the Mercur and Manning companies respectively.

the asphaltite had been held under denouncement, and exploited with the view to utilizing it as fuel. It is reported that several tons of vanadiferous ashes were sent to France for treatment, but beyond this very little asphaltite was mined. No work has been done since 1899. Several of the less important deposits in the northern portion of the district have been developed to a slight extent, and the asphaltite used locally for fuel.

There is a contact between folded Jura-Trias and Cretaceous sedimentary rocks on the southwest, and more recent eruptive rocks on the northeast, which contain the silver veins of Andaychagua and the copper-silver veins of Yauli. The famous Carahuaera silver mine, and several less important, are in the contact-zone. The Jura-Trias rocks are coarse conglomerates and sandstones, and the Cretaceous is represented by thin-bedded gray and green shales and limestones, the latter predominating. In the vicinity of Toldorumi the intrusion of the eruptive rocks on the northeast has brought up a narrow belt

*Abstract from paper in *Trans. Am. Inst. M. E.*, February 1909.

of slates. The veins of asphaltite occur in a well defined belt in the sedimentary rocks, following the stratification, and are approximately parallel, therefore, to the contact mentioned above. Asphaltite veins have been found over a distance of 15 miles. The veins occur as lenses, varying from 0.5 in. to 22 ft. wide, the maximum known length of a lens being about 500 ft. These veins are not confined to one bedding-plane, and may not only break through from one to another, but there may be asphaltite to the extent of 5 ft. in width, filling each of two or three contiguous bedding-planes. Thus there appear to be three veins, separated by single layers of shale from 3 to 10 in. thick. There is evidence of movement subsequent to the intrusion of the asphaltite, which is shown by its peneillate structure of the asphaltite, and by numerous faults of small throw.

The asphaltite is black, lustrous, and softer than ordinary bituminous coal. The hardness does not appear to be affected by the amount of ash present. The material completely lacks evidence of clay-bands and the columnar structure common to most bituminous coals. It breaks clean from the walls, though the country rock adjoining often contains a large amount of carbonaceous matter. No pyrite was observed in the asphaltite at any of the exposures. The mode of occurrence of the asphaltite is essentially the same at the various exposures. The vein has been developed by five tunnels, aggregating about 2000 ft., within a vertical elevation of 300 ft. The tunnels are from 150 to 500 ft. long. Table I, a record of samples from tunnel No. 2, serves to explain in detail the variation in the width of the vein, and the amount of vanadium contained in the asphaltite:

It is apparent that the percentage of ash in the asphaltite from the Yauli district varies considerably. The amount of vanadic oxide in the residue after burning varies between wide limits. This appeared to suggest that the vanadium was independent of the mineral matter in the asphaltite and that, therefore, its origin might be traced to the hydrocarbon portion. The last column in Tables I and II gives a factor derived by dividing the percentage of vanadic oxide in the asphaltite by the percentage of hydrocarbon, considering that all combustible matter was hydrocarbon. It appears that this factor is constant enough to be considered as an index of the solubility of vanadium (probably as sulphide) in the hydrocarbon. About 100 ft. east of the asphalt vein there is an outcrop of a dike of devitrified perlitic obsidian, about 50 ft. wide. It appears to have been intruded along one of the bedding-planes. There are no contact-phenomena other than a noticeable hardening of the shales, though the dike appears to have been the cause of the formation of a zone of pyrite replacing the shale in the foot-wall of the asphaltite vein.

In 1905, a party of Indians, who had been in the mountains searching for coal, brought to Antenor Rizo Patron, metallurgist at the Huaracaca smelter, on the Cerro de Paseo railway, samples of a material thought to be coal. The material came from a prospect near the crest of the main Cordillera, within the concession of the hacienda de Quisque. The prospect had been located for coal no less than three times previously, but was abandoned in each case when it was found that the material contained a large amount of sulphur. Under these old locations the prospect became known as Minasagra. Upon analysis the material was found to contain a high percentage of vanadium.

The area under consideration lies along the western limb of a broad anticlinal in Jura-Trias and Cretaceous rocks. The series in this locality is composed of green shales, thin-bedded limestones, and red shales. The red shales are succeeded to the west by a great thickness of limestones, of which the main range is composed. The vanadium deposit occurs entirely within the red shales. Igneous activity in the form of the intrusion of dikes, laccoliths, and domes, has been a feature throughout a large area in this portion of the Province of Pasco, and these forms have been controlling factors in determining the local topography. It is evident that the vanadium locality has been a unique centre of this activity, there being no less than four systems of dikes, the entire area being probably underlaid by a laccolith. The vanadium deposit is a lens-shaped mass composed principally of three distinct constituents, which occupies one of the faults. The maximum width of this mass is 28 ft., and though the length is partly concealed, it cannot exceed 350 ft. The strike is about N.20°W., and the dip is 75°W. The three materials, in order of relative amount, are: (1) Quisqueite; a black lustrous hydrocarbon; hardness, 2.5; sp. gr., 1.75; fracture, conchoidal. Name derived from the hacienda in which the deposit is found. (2) Coke; a dull black, vesicular hydrocarbon; hardness, 4.5; sp. gr.,

2.4; fracture, conchoidal. This coke contains globules of quisquite. (3) Patronite; a greenish-black mineral; hardness, 2.5; sp. gr., 2.65 to 2.71; fracture, uneven. Name derived from that of Antenor Rizo Patron, who first recognized that the mineral contained vanadium.

The following minerals, found in very small amounts, were recognized under the microscope: Bravoite; a reddish-yellow mineral in patronite. Composition (Fe, Ni) S₂; hardness and specific gravity not known. Also an undetermined silicate mineral resembling halloysite.

Analyses of these minerals made by Hillebrand show:

Also small amounts of ferric oxide, manganese, chromic oxide, and alumina.

The silicious matter, and possibly the carbon, may be considered impurities, and patronite approaches in composition a compound of vanadium and sulphur, which can best be represented by the formula V₂S₅ + nS. The nature of patronite and its relation chemically and genetically to quisquite in coke is made clear by a close study of microphotographs. These show patronite, quisquite, coke, bravoite, and silicious mineral, in varying proportions. Quisqueite is a black material, generally in the form of globules, though sometimes only a thin film lines the cavities. The coke is black, but duller in luster than quisquite, and is found in the sections as an irregular network resembling a sponge. Patronite fills all the portion not occupied by coke and quisquite, and is the light material showing the greatest relief. Bravoite is of irregular occurrence. The white segregations are the silicious minerals referred to above. It is clear that the materials are segregations from a mass which was probably originally homogeneous. Quisqueite was the first material to segregate. The larger portion was crowded to the walls. It probably segregated through insolubility in the remaining mass, rather than on account of difference in melting-points, for it appears to have been viscous after the segregation of the coke. Moreover, it was probably unstable at the temperature then existing, this being suggested by the globules, which are more or less coked. The coke segregated after the quisquite, and though nearly pure, it must have had the consistence of a paste, for it was able to form solid, fairly homogeneous masses.

Before the solidification of the patronite took place,

there must have been a disturbance, due probably to the upward movement of the mass. This is shown by a crushed condition of the coke, and to a less degree of the quisquite. Patronite was the last mineral to solidify, and from its associations appears to have been the eutectic of the mass. It fills all of the cracks and spaces between the globules of quisquite and the walls of the cavities. The fact that patronite is of the nature of a eutectic serves to explain why its composition does not accord with the usual valency of vanadium, as eutectics, though generally constant in composition, are seldom compounds to which a formula may be assigned.

Patronite appears to have had the peculiar property of being able to permeate the porous country-rock, even to the degree of saturation. At some period, after the mass had become solid, a convulsive movement re-opened the fault-line, rending the mass from end to end, as shown by a clay-filled fissure. The red shales are not only crushed, due to faulting prior to the appearance of the mass, but are much bleached, probably from the action of sulphurous vapors.

Two minerals of approximately definite composition have been found upon the surface. Both are hydrated oxides of vanadium, and though partial analyses only have been made, they appear to be new species. Hillebrand is inclined to regard them as salts, not as oxides or acids. The first, which will be called the 'red oxide', has been analyzed by Hillebrand. It occurs as globular aggregates with radiated structure, though amorphous material is common. The color is deep brownish red to red; streak, red; sp. gr., 2.30 to 2.48; hardness, 2.5. The second, which will be called the 'brown oxide', shows loss on ignition, 19.0, and vanadic oxide, 72.50%. The brown oxide is found along the outcrop in irregular amorphous masses, none having a tendency toward more definite structure. It is dark brown in color; streak, dark brown, sectile; hardness, 2.0; sp. gr., 2.30. It has the peculiar property of swelling and disintegrating when placed in water.

TABLE IV. ANALYSES OF RED AND GREEN OXIDE.

	Red Oxide.	Green Oxide.
	%	%
Vanadic oxide, V ₂ O ₅	67.60	57.33
Vanadium tetroxide, V ₂ O ₄	trace	4.76

Silica	1.17	0.57
Titanic oxide		0.07
Alumina	3.31
Phosphoric oxide (?)
Ferric oxide		19.53
Lime	4.30	0.70
Magnesia	?	trace
Water	20.81	13.89

At a depth of 8 ft. from the surface, the red and brown minerals are replaced by one having a greenish-black color. It is generally amorphous, though along openings or water-courses it appears velvety, which appearance, under the microscope, is resolved into aggregates of acicular crystals, resembling a form of malachite. The sp. gr. of the mineral is 2.52.

Solution of vanadium compounds is in process continually, and waters flowing from the tunnel show a

considerable amount of vanadium in solution. Waters percolating through the walls of the tunnel deposit an orange incrustation which Hillebrand says is apparently a hydrous calcium salt of hexavanadic acid, that is, $\text{Ca}_2\text{V}_6\text{O}_{17} + x\text{H}_2\text{O}$. The x is between 10 and 11. Water is about 22%. The calcium oxide is about 12.8%, and that of V_2O_5 about 65.4.

The occurrence of vanadium in hydrocarbons is not confined to Peru. It has been announced by Kyle in the ash from a coal (asphaltite?) found in the Province of Mendoza, Argentine Republic; also from other localities mentioned in Clarke's 'Data of Geochemistry'. I have found it in the ash from an asphaltite from Page, Oklahoma. The material contained 1.10% ash, of which 0.19% was vanadic oxide. A review of the original articles describing the above-mentioned occurrences has convinced me that all of these materials are closely related. They all appear to be asphaltites containing an appreciable amount of sulphur.

Asphaltites are probably derived from petroleum. All asphalts contain sulphur, and the hardness of the mineral appears to depend upon the amount present. The occurrence of vanadium in asphaltites appears to depend upon three factors: (1) Vanadium, as oxide, disseminated through a rock of a fair degree of porosity. (2) Impregnation with a hydrocarbon. (3) A source of sulphur or sulphuretted vapors. The first of these conditions undoubtedly often exists over large areas, in the two districts in Peru under consideration; the two remaining conditions have undoubtedly been brought about by the intrusion of the dikes. It would seem, therefore, a safe forecast, that most asphaltites containing more than 2% sulphur also contain vanadium. The Quisque deposit may be interpreted as an extreme phase of differentiation from asphaltite, the intrusion of the dikes probably having had the effect of successively concentrating the vanadium. The unique climatic conditions account fully for the formation of the large aureole of oxidized ores. Had there been erosion by water, even to a slight degree, the oxidized minerals would have been carried away, instead of being permitted to accumulate in the porous country-rock.

From June 1906 to January 1909 there has been produced and shipped to the United States 1800 tons of the oxidized ores, containing about 20% vanadic oxide, and the product from roasting 400 tons of the sulphide ore, namely, the patronite.

Modifications of the Mond gas producers worked out by Frank and Caro in Germany adapt them to the use of peat for fuel. By this process the greater part of the combined nitrogen of peat may be recovered as ammonium sulphate. American peats show more than 3% nitrogen. Peat with but little more than 1% yields enough ammonium sulphate to pay for running the plant, for maintenance, for gasifying the peat, and for a profit besides. A large part of the gas remains as additional profit. Peat beds of proper character may therefore soon become profitable sources of power and ammonium compounds in the United States. By the Frank and Caro process, peat with from 40 to 50% of water can be used.

SYMMETRIC STRUCTURE IN LIMESTONE AND LAVAS.

By R. H. CHAPMAN.

*In 1902, while crossing the Rocky Mountains in the Lewis and Clark Timber Reserve in Montana, I found several specimens of limestone of peculiar structure. One of these was in a position to be photographed, and Fig. 1 shows the specimen. The block is about 45 in. long, 30 wide, and approximately 24 thick. These forms I have called 'firkin' limestone, as they suggest butter-tubs of various sizes. The cylinders, which lie with their major axes perpendicular to the bed-planes, range between 6 and 18 in. diam., and are formed of concentric shells of hard blue-gray limestone, often separated by narrow bands of brownish-yellow gritty material. These rings weather and break from the blocks in circular segments of various thickness. Where they occur in large masses which have been long exposed to the weather, the surface of the blocks seems to be modified by erosion, and to assume a form shown in Fig. 2, which is from a photograph by Bailey Willis, who describes the rock as showing large concretionary or 'coralline' masses.

In this mass many of the forms appear to be of irregular outline, and while the circular form is predominant, it is not so to a great extent. In this specimen the irregular forms seem to be due to weathering, fracturing along curved planes which are often tangent to the structural cylinders (Fig. 1, near head of hammer). Fig. 1 and 2 are from the same region, but separated by many miles. These firkin forms occur in the upper part of the Siyeh limestone, about 500 ft. from the top. This limestone is one of the beds in the Algonkian series described by Willis,¹ who also says: "Mr. Walcott states that these forms are similar to those found in the pre-Cambrian rocks north of Helena, Montana, but as yet they have yielded no evidence of organic origin." Walcott also states that he finds similar forms in the pre-Cambrian rocks in the Grand Canyon of Arizona. In several localities in northern Montana a modified form of structure was observed, the 'firkins' having an elliptical cross-section instead of a circular one. This modification is probably accomplished by pressure, which may have been supplied by the intrusives described by Willis as occurring in this series of rocks. "Siyeh limestone" is often characterized by peculiar internal structures, and by large concentric growths; indistinctly fossiliferous, associated with an intrusive diorite sheet and dikes, with an extrusive diabase flow at its upper surface * * *

Stutfield and Collie mention finding:⁴ " * * * petrified stems of pine trees that have been broken

off about a foot from the ground," and so forth. These forms are described as existing below 9000 ft. in the ascent of Mt. Murchison, which is about 50 miles north of the C. P. R. at Field, in latitude 52° N., and $116^{\circ}30'$ W. This is undoubtedly the same 'firkin' limestone.

From this, and from Mr. Walcott's statement, it seems that this peculiar structure is widely dis-

**Report No. 36 N. Y. State Museum* (Historical), 1884, 1895.

Limestone found in Franklin county, Missouri, by Burchard, shows circular rings similar in appearance to those in Fig. 1, and Burchard states that the

Fig. 3. *Conchoidal Structure in Lava.*

whole form is cylindrical, very like the 'firkins' of the Montana specimen.

Interesting in comparison with the limestone forms are Fig. 3 and 4, which are representations of entirely different rocks. Fig. 3 is described by Gilbert as: "Conchoidal structure in lava near Cascade, Oregon." It strongly suggests the limestone form in the fracture-planes due to weathering, which to a large extent parallel the joint-planes in the rock. Fig. 4 is by Irving, and is described as: "Spheroidal

Fig. 4. *Spheroidal Weathering of Porphyry.*

weathering of mica diorite porphyry," found near Terry in the Black Hills. In this illustration the similarity of the weathered surfaces to those of the limestone from Montana is striking, and that the elliptical ring-like structure of the rock-mass is definitely related to the joint planes is evident.

SCREEN ANALYSIS AND GRINDING
EFFICIENCY.

By ARTHUR YATES.

*The tests recorded in this paper were made at the mill at Redjang Lebong, Sumatra. The practice consists in taking samples of an average of about 30 oz. dry weight, representing the day's run. This is taken from the pulp going to the tube-mill amalgamation-house. It is graded or sized wet for 20 min. on each screen, using No. 60, 100, 150, and 200-mesh screens. The samples are then dried and re-sieved. The results of dry-screening only are used in the calculations.

The results show that when operating under regular conditions the percentage-extraction on any particular sized product is a fixed figure quite independent of the assay value of the charge. From this it follows that, given the percentages of the various grades, one can calculate the percentage-extraction for the whole sample, or, given the total percentage-extraction or efficiency-number one can, with the help of a factor, obtain a figure which should correspond closely to the efficiency-number for the sample or the percentage extraction.

Percentage extraction
factor

efficiency-number.

Efficiency × factor = percentage-extraction.

The factor should be obtained from a long series of sizing-results and assays, otherwise a material error may be introduced. These factors assist in finding where errors occur, and any serious discrepancy should be at once investigated. At Redjang Lebong work at present is in a transitory stage, the stamping and tube-milling conditions continually changing as plant is increased, so I have not been able to use the factors over any longer period. I find that a fairly regular factor for the sand-plant extractions can be obtained direct from the daily tube-mill sizing-efficiency number.

For correct efficiency-numbers it is necessary to use a large number of screens, otherwise considerable errors may be introduced, but for general plant-work a few standard sizes answer very well, in comparing the work done and the distribution of assay values. Unless the percentage of coarse grades is high, no great error enters into the calculation, but in the case of fine screens small differences of the sizes produce large differences in the percentage efficiency; thus the separation of the 200 product into sand (0.002 in. to 0.0025 in. mean) and elutriated slime (0.001 in. to 0.0015 in. mean) in place of calculating on a basis of 200 only (0.001 in. to 0.002 in. mean) completely alters results. For instance, the June sand sizing given above works out 349.0 by one method, and by the other 361.2, while the slime sizings give 596.3 and 484.4 respectively. The stamp mill at Redjang Lebong consists of seventy 1000 lb. stamps. The stamp duty is as follows:

Screen.	Tons.	Horse-power.	Daily Stamp Tonnage.
16 mesh	280	183	4.0
20-mesh	259	183	3.7
35 mesh	210	183	3.0

There are six Schmidt-Davidsen tube-mills, 16 ft. 6 in. by 4 ft. 6 in., outside measure; only four of these are used. The mills are lined with a local eruptive rock, and are fed with vein pebbles. Each mill consumes on the average 47.5 hp., and on starting requires considerably more. As the result of a large number of screen-analyses I obtain the following results:

BATTERY SCREEN-SAMPLES.

Screen.	+100.	+150.	+200.	—200.	Efficiency No.
16 mesh	45.7	8.2	5.2	41.1	259
20 mesh	43.2	7.9	6.2	42.7	271
35 mesh	24.8	9.3	9.2	52.7	326

AFTER TUBE MILLS.

Tube-		Stamps		Mesh mills			
70	16	3	4.8	23.8	8.5	62.9	393
70	16	4	1.1	7.2	17.7	74.0	438
70	20	3	3.4	13.8	14.4	68.3	415
70	20	4	1.3	7.1	14.0	77.5	444

In placing the tube-mill efficiency-numbers side by side with published results from other mines, it was suggested by S. J. Truscott that the introduction of the power-figure and the tonnage would make the comparison fairer, as power and output apparently varied so much in different districts. This gave a figure which we called the relative efficiency:

Relative efficiency =

Sizing efficiency number × tons
horse-power

It will be seen that it affords a fair means of comparing all types of crushing and grinding appliances, and should, apparently, prove useful in assisting in the selection of the most efficient and economical machine. The following table gives a comparison of the above crushing figures:

Stamps, Number.	Screens, Mesh No.	Tons per Stamp per Day.	Tube-mills, Number.	Tube-mill Daily Tonnage.	Horse-power.	Grinding Efficiency.	Relative Efficiency.	Relative Efficiency to Unity.
70	35	3.0	..	210	183	326	373	1.00
70	20	3.7	..	259	183	271	383	1.02
70	16	4.0	..	280	183	259	396	1.06
70	20	3.7	3	259	325	415	330	0.88
70	20	3.7	4	259	373	444	308	0.82
70	16	4.0	3	280	325	393	341	0.91
70	16	4.0	4	280	373	438	328	0.87

The table discloses that stamping with 35-mesh screen compares favorably with the coarser screens, and that when running tube-mills in conjunction with the stamps the relative efficiency is not so high as with stamps alone, but there is a tendency for a higher efficiency with the latter when coarser screening is used. I have not been able to find any complete sizing results of work done in grinding-pans, Chilean mills, Huntington mills, and the like, so I cannot compare the relative efficiencies of these machines with stamps and tube-mills, but a comparison with those machines would be most interesting.

*Abstract from paper read before the Chemical, Metallurgical & Mining Society, of South Africa, December 19, 1908.

GEOLOGIC ESSENTIALS OF A MINE REPORT.

By COURTENAY DE KALE.

*Whether an engineer's advice be frankly optimistic, or frigidly conservative, should depend in no small degree upon the character of the client and the purpose he had in ordering the examination, but the kind of enquiry he should make to secure data for a mine report does not depend upon the use to be made of it. This may startle those who have given their adherence to current scientific orthodoxy, for I am aware that the confession of faith by the engineering hierarchy affirms that an examination should yield fact and nothing but fact, and that every opinion should be so well grounded as to partake of the nature of eternal truth.

An opinion is not fact, and no amount of argument can wash out the last color of uncertainty that leaves it still something less sure than demonstrated verity. If any man among you has ever read a mine-report that did not try to persuade one to accept opinions, I would suggest that the next step in order would be to test the intellectual reliability of the man who wrote it. Lest you be inspired with the belief that a mine-report is a thing lacking in definiteness because of inherent difficulties in obtaining data, it may be well to affirm that undemonstrability in varying degree is a feature of nearly every enterprise upon which men pitch their faith and risk their money. Human affairs are not regulated by mathematic rule. No civil engineer's estimate ever advised a capitalist how much the construction of a railroad would actually cost; a man of experience may have hit it by a prudent assumption, which he might term an estimate multiplied by a factor of safety—but the factor of safety expressed his opinion. It may have been a better one than yours or mine, but still it was an opinion. It was because he had had experience enough to know how to guess wisely that he, and not you or I, was able to make so close an estimate. The world works out its plans by a good combination of fact and guess, and the value of the guess depends on the experience and common sense of the man who makes it. But the profound guesser is ever a man of deep humility of spirit. He is not puffed up because of his skill; indeed, he is largely unconscious of the process by which he exercises his gifts of seeing deeply. He is more reverent in the face of fact, and more zealous in seeking it, than the man who thinks lightly of responsibility. He who is conscious of the intuitive faculty is a perilous leader.

How shall we make this square with the affirmation that the character of a mine-report should depend upon the use your client proposes to make of it? If the desire be to employ the information as a warrant and guide for development, the engineer's point of view would, or should, differ widely from his attitude toward the problem if the purpose were to buy or sell the property. His responsibility is altered by the intent of his client: if a man be inclined to put money into mining carefully and prudently, as he would purchase lands for development or establish

a factory, he would require entirely different advice than if he were disposed to take chances in the hope of winning largely. In short, from the point where a man may proceed chiefly upon opinion based on scant indications of outcrop, every grade exists up to the point where he deals in measured quantities ample for justifying all his recommendations; and every grade exists also between the judgment he will deliver for a client who needs to be held back from reckless risk, to that required by the timid sort for whom any expression of opinion would be a clear injustice because of his abhorrence of chance.

The engineer who would give the same kind of advice relative to a given property under all sorts of circumstances is one whose competency would be open to doubt. A man must be human to deal adequately even with problems of geology and the economics of mining.

Having established the heterodoxy that a mining engineer must really use the judgment that comes from experience, and not decide by rote and rule of thumb, the next point to fix in mind is that he should distinguish between fact and opinion as he would between light and darkness. Moreover, he must distinguish between competent and incompetent fact in a spirit of the highest professional self-abnegation. There is a tendency in human nature to magnify attainments, to exalt the knowledge of the art by putting more of it in evidence than is necessary. Greatness consists to a considerable extent in stripping off the encumbrances which arise through complicating our performance with unnecessary things. The unnecessary is always dangerous: it lays one open to error, confuses the mind, and obscures the truth. Only those facts which bear conclusively upon the point at issue are competent as bases from which to draw conclusions.

When an engineer arrives upon a property it is his duty to observe everything which the limits of his engagement permit. Here again the engineer cannot declare what he will or will not do in regard to time. He does the thing that has the largest immediate economic value for his client, from a fleeting reconnaissance to a complete and minute examination. There is a curious tendency among engineers to flourish a vast deal of indeterminate geology in mine-reports. It is the easiest side of the work from which to gather wool to pull over the eyes of the laity. I say this without any malicious imputation. It is a fact of observation from the reading of multitudes of mine-reports. Even men who are amply trained and ripe in experience are drawn into this peculiar groove. In its exaggerated form it is pure charlatanism; in its milder manifestations it is a frill of the craftsman that adds nothing to his dignity, and weakens his power to sift evidence.

So far I have dealt with the question on the side of integrity, apart from concrete instances. A man sent to examine a mine is usually hurried. Opportunity to exhaustively study a deposit is rare. Such work as was done at Ely, Nevada, at the Utah Copper mine in Bingham canyon, at Miami and Ray, in Arizona, are exceptional. The elaborateness of the study naturally depends upon the financial responsibility

*An address delivered before the Geologic Society of Stanford University, April 13.

involved. In any case the purpose of the examination, and the end reached, are the same, namely, the ascertainment of facts of economic importance. The first consideration is the presence or absence of the substance sought in quantity sufficient to warrant further examination. The prime matter then is the metal in the deposit. Geological indications must not count in the initial stages of an investigation. The nucleus is the ore. Find that first, and work outward into the successive layers of the problem. Before strictly geological work should begin the engineer should acquaint himself with the character of the ore, and its distribution in the lode. He should know its mineralogic habit, its gangue, and the associated phenomena when the lode grows richer or leaner. Hence the first work to be done is chemical and mineralogical, and the examining engineer should go equipped for qualitative analysis and mineral determination. Excellent kits are now provided for travelers in compact form, sufficient for a wide range of accurate work.

In the process of studying the vein some information as to its derivation may be obtained. But the matter of vein-genesis is one of the most difficult with which the economic geologist has to deal in the practice of his profession. This was in my mind more than any other consideration when I spoke of the tendency to overload a report with indeterminate geologic statement. It is the fashion today to state how the vein was formed. He is a courageous man indeed who will write a report without attempting to pronounce on this question, and usually it is the one thing above all others that had better be dealt with warily. You may be decidedly of the opinion that the vein is an impregnation, or a metasomatic replacement, but only an exhaustive study can give large significance to those facts. Indeed, without microscopic evidence one may err as to either deduction, and further revelations as to the details of the process are needed before the conclusion can possess much economic worth. It must be remembered that the public is eternally demanding that the mining engineer become a prophet, and he in turn is trying with all his might not to disappoint the hopes held of him. He often yields so far as to stretch his geology beyond the sanction of his conscience. It is dangerous business, that of prophecy. But an engineer has no right to hedge; he should state his conviction, uninfluenced by the use or misuse likely to be made of it. After elaborate examination of the local geology wonderful predictions have been made; the classic case is that of S. F. Emmons at Leadville. But the engineer must not be led by the example of work done with such detail to promise continuity of deposit from superficial evidence. Ore deposition is usually a matter of chemical reaction, and the thing to demonstrate is that at points beyond the scope of present observation in mine-workings, the necessary chemical agents and reagents were probably present. There is the first great limitation. The man who has the right type of mind will wait longer and labor patiently before he will announce the continuance of the same chemical conditions, as shown by mere end-reactions, to any considerable distance beyond the

point of his pick. He may guess, and his experience will add large money-value to his surmise, but the true geologist will wait for proof before he announces the manner of genesis of a vein, or deduces extension in depth from the fact when he has gained it.

The second great point to determine is the localization of ore into shoots. The habit of nearly all deposits is to occur in zones of enrichment. It is important to know whether these are due to segregation, to deposition in channels or spaces of greater porosity, or to other causes. But here again the microscope and exact chemical analysis are usually necessary. Unless the cause of the localization can be demonstrated it were better to hazard no conjecture, resting content with the determination of the size and position of the shoot. The existence of secondary enrichment should be ascertained if feasible. In the case of copper this can to some extent be done, although the occurrence of primary chalcocite having been conclusively proved, the problem is not always easy. The existence of chalcocite and bornite in great abundance will, however, always raise a fair presumption in favor of an enriched deposit. The engineer here confronts another limitation. Exhaustive work is usually needed to demonstrate the fact of secondary enrichment, and as the term has come rightly or wrongly to convey to the layman an impression of substantial size and value, the conscientious engineer should ordinarily be content to define and sample the ore-shoots, and leave the questions of whence and how the metalliferous solutions came as a matter to be determined by later incontrovertible evidence.

As most ore deposits exist in the form of veins it becomes pertinent to determine how the zone which has become mineralized had been prepared for either the alteration or the filling that has taken place. The most frequent agents are faulting, shearing, and alteration by contact metamorphism. Magmatic segregation, while usually insufficient to cause enrichments of economic value, is potent in furnishing deposits which through further concentration by solutions become valuable. The solvent power of water in the rocks, aided by carbonic acid and other gases, is great enough to take up metallic compounds, and convection and diffusion will transfer the salts and ions respectively to points where reactions resulting in deposition can occur. Once begun, this process will continue so long as conditions remain unchanged, and the accumulation of metal will increase until masses of great size may result. Diffusion can go on without the previous existence of any crushed area or zone of special porosity, and it may be accomplished without any movement of the solution itself. The juxtaposition of two masses of rock presenting important differences in chemical composition promotes the formation of orebodies along the contact by virtue of the increased opportunity for chemical interchange. This again may be independent of what are known as contact phenomena. In fact such phenomena, which are due to wide differences in temperature between the two rocks when brought into their existing relations, are not necessarily conducive

to the formation of ores. They are quite likely to result in reducing the porosity. The movements of rock magmas at great depths are extremely slow; violent intrusion is mostly superficial and results in the formation of dikes, sills, and occasionally batholiths. Hence the invasion of a group of deep-seated rocks by magmas frequently occurs under such conditions that the temperatures of the two are not far apart, and no important changes in character result along their borders.

The determination of the manner in which the ore-bearing zone was made ready for alteration is then one of the prime geologic facts which the engineer should seek to ascertain. Discrimination between fault-planes and shear-zones leads to useful deductions. While fault-planes may reach to profound depths they are also liable to be erratic. Shear-zones are more reliable, and may be more safely taken as indicators of the existence of deeply continuous shoots of enrichment.

The orebodies along a contact are prone to be connected by stringers, and may reach to great depths; segregations incline to the formation of isolated bunches, but where one is found many may be discovered by exploration. While these circumstances may not encourage boldness in prophecy, they are significant as indicators, from which the man of experience can draw valuable conclusions. Moreover, these conditions are usually capable of being ascertained with reasonable definiteness, even during a hasty reconnaissance.

From the foregoing it is evident that even a cursory examination requires attention to the surrounding rocks. The country rock is the correlative of the orebody. It is often related most intimately to the genesis of the ore, and some hint of that function may appear in the data the engineer's field work may supply. The exact kind of rock, however, is of less importance than the chemical characteristics. Rock-names are often the cloak of superficiality. It means very little to say that the hanging wall is granite, and the foot-wall gabbro; but it means a great deal to say that the hanging wall is a granitoid rock, highly silicious, with orthoclase feldspar, scant biotite, and abundant accessory hornblende, while the foot-wall is an apparent gabbro, with abundant labradorite, much pyroxene, primary pyrite, and so forth. These are facts which the field-worker can determine positively in a few minutes, and they convey genuine information. It is of value to state the relationship of stratified rocks to the deposit, in which case the kind of sedimentaries and their condition should be noted. But if you do not recognize a rock, do not attempt to name it. State what you see, describe the mineralogical peculiarities determinable by such means as you have at command, and let it go at that. The great majority of crystalline rocks do not admit of close classification until they have been studied in detail with the aid of the microscope.

Almost invariably a vein or metalliferous mass represents a zone of weakness. In consequence subsequent earth-movements affect these less-resistant areas with special facility. Fault-zones constitute

expansion-joints in the lithosphere, and veins are largely associated with these lines through which the earth-tension is relieved. The evidence of movements subsequent to the filling of the veins is usually recorded so that the trained observer will find no difficulty in recognizing them. This is one of the facts worth while to ascertain. It means that there has been afforded opportunity for re-arrangement of the primary ore by later alteration, solution, and re-deposition. It often involves rejuvenation of the circulation of heated waters from below. I have in mind a particular case at the Exposed Treasure mine near Mojave, California, where an original brecciated zone was produced by shearing. This was followed by silicification, resulting in a dense cherty filling carrying large quantities of finely disseminated pyrite, with some chalcopyrite, but the precious metals were almost totally absent. Later the region was disturbed by movements induced by the intrusion of basic igneous rocks underlying the older acidic magma which had formerly caused extensive outflows of rhyolite. The basic rocks were erupted many miles away, and did not invade the country immediately surrounding the lode, but the equilibrium was disturbed, and in its re-establishment faulting occurred which brecciated the primary vein. Through this channel arose solutions rich in lime, iron, and copper, carrying gold and silver. The significance of these facts in determining a warrant for development in depth is apparent.

It must be observed, however, that faulting is not the only means by which movements may be produced in veins. Most lodes are of the replacement type; if not strictly so, at least alteration is commonly attendant on the genesis of the deposit. Rarely such changes take place without change of volume. Usually there has been either shrinkage or expansion. Shrinkage leads to complex fissuring within the lode, which may be healed by subsidiary venation. It often possesses great economic importance. It is always a point worthy of note. Expansion of volume leads to 'slips,' that is, joints or parting-planes produced by relief of the pressure from squeezing. These are commonly conchoidal, although not necessarily so. Such expansion is likely to record itself by dislocations of the wall-rocks, and sometimes by coarse brecciation of the lode itself, but of a type entirely different from that commonly yielded by brecciation due to faulting; the brecciated mass in this case is re-consolidated by the pressure without interstitial filling by foreign material. Brecciation of a lode by faulting leads to profound effects; 'slips' from expansion may affect a lode to limited depths only, because the character of the material may not remain constant far below the point of observation.

Another circumstance of vital moment, when it can be ascertained, is the probable amount of erosion since the vein was formed. This may reveal, aside from internal evidence given by the vein, whether the visible ore is probably primary or secondary. In the absence of deep workings the determination of this fact is often of high economic value. Enrichment of the upper part of a vein is to a certain ex-

tent evidence against the continuity of like metallic content to a considerable depth. In the case of gold ores, unassociated with much copper and iron, it would lead to grave suspicion of superficiality. With copper the same conclusion would not be warranted; nevertheless I have observed many cases where it applied with force even to that metal. In an arid or semi-arid country the existence of an abundance of sulphides near the surface is in itself a strong evidence in favor of the ore being primary. The conclusion, however, is not always justified. I have been surprised to find remarkable superficial secondary enrichments of copper sulphides in two widely separated regions under the most diverse climatic conditions. One of these regions is along the north shore of Lake Huron, where veins through sheared diorites are frequently rich in chalcopyrite close to the outcrop, but prove lean, and sometimes barren, in depth. These rocks have been glaciated, and the enrichment has apparently been accomplished by leaching upward as a result of capillary flow induced by evaporation at the surface. It is quite improbable that percolation downward occurs through the capillary openings of these dense homogeneous rocks. The other region is along the semi-arid western slope of the Sierra Madre in the State of Sinaloa, Mexico, where the destructive effects of meteoric agencies are extreme, and the annual erosion of the disintegrated rock-surfaces during the violent rainy season is excessive. In spite of these conditions copper veins in the andesitic rocks are often characterized by superficial enrichments of chalcocite. In both cases the enrichments noted were conformable to the topography, which circumstance alone would be a guide to the interpretation of the phenomenon.

I may call attention, by way of example in determining whether an ore be primary or secondary, to an interesting case in the Bazonopa district in southwestern Chihuahua, Mexico. The Guadalupe vein at La Cumbre de San Manuel is one of a series of remarkable silicious lodes, carrying sulphides of iron and copper, with varying amounts of gold and silver. The sulphides are found at the very outcrop, affording the first hint that the ore was primary. The lode lies between an acid crystalline rock of dioritic character, and a basic andesite. The andesite has been intruded by dikes of trap, approximately parallel with the lode. Erosion has carved a deep canyon, with sides sloping at about 38°, in the relatively soft andesite. The vein outcrop extends along the base of steep scarps of the diorite near the top of the ridge. The vein being silicious stands above the andesite, but by reason of a gouge between it and the diorite it shows a tendency to detach in blocks as denudation of the andesite undermined its support. In the bottom of the canyon, blocks of the ore were found in great quantities. Some concentration of gold had occurred adjacent to the gouge, that had yielded rich pockets to the early Mexican miners. The mass of the ore, however, was not secondarily enriched. The evidence was conclusive. Erosion was proceeding faster than decomposition, and the ore was clearly primary.

The points which are essential in the geologic ex-

amination of an ore deposit may be summarized as follows: (1) Presence of ore. (2) Character of the ore. (3) Distribution of the ore in the deposit. (4) Ore-shoots. (5) Mineral associates of the ore. (6) Secondary enrichments. (7) Cause of the ore-bearing zone. (a) Mechanical. (b) Chemical. (8) Country rocks. (9) Contact phenomena. (10) Subsequent movements in the vein. (a) Faulting. (b) Shrinkage. (c) Expansion. (11) Order of deposition of minerals in the vein. (12) Erosion in its relation to primary or secondary ore.

There may be many other salient conditions which would be observed, but the foregoing are those regarding which as much evidence should be obtained as possible. Concerning these there should be no guessing. As far as the situation warrants, the statements should be those of simple and demonstrable fact. A well trained field geologist will obtain a great amount of information from only a few days' work in the field, but the correlation of these items for deduction of probabilities concerning the ore deposit is usually so speculative as to involve danger of falling into error. The report itself should contain nothing but proved facts and the logical inferences from them. Additional data should be submitted in the form of an appendix, never in the report itself. To do otherwise is to confuse reality with surmise, and to reduce the value of the report from an economic standpoint.

I affirmed in the beginning that the advice given should depend upon the use to which it is to be put. It is now plain how the engineer may gauge his discretion. The report itself must be a document based on ascertained fact. It must present the things on which opinions cannot differ. A supplementary statement, however, can convey the results of observation which are open to conflicting interpretation. Here the experience of the engineer counts heavily. Here he may pass beyond the realm of demonstration to that of opinion. In this he may render advice in accordance with his expectations based on analogy, tempered by considerations of the use or misuse which may be made of the convictions to which he has been led. The opening of mines consists in plunging into the unknown in search of treasure. It is as much a part of the engineer's duty to forecast probabilities as to determine facts, but the two must not be entangled. The known and provable must be separated by a sharp plane of cleavage from the problematical.

The electrolytic method, now used so largely for refining copper, silver, and gold, has been but little used for tin, because this metal is easily refined by other methods. An electrolytic process, however, is in use at an establishment near Liverpool. Anodes of tin with 10% impurities are placed in a 10% solution of Na_2SO_4 with cathodes of block tin, and traversed by a current of 0.06 amp. per sq. in. at a voltage of about 0.2, the temperature being kept at about 194° C. About 1% by weight of sulphur should be added to the bath before each renewal of the anodes, to combine with the impurities in the anode and act as a depolarizer, so that electrolysis can be commenced at a low voltage.—*Scientific American*.

ADJUSTABLE PYROMETER STAND.

Written for the MINING AND SCIENTIFIC PRESS
By L. W. BAHNEY.

The stand shown in the illustration was made especially for the purpose of holding a tube, either of clay or of fused quartz, in which are enclosed the platinum and platinum-rhodium leads that constitute the couple of the Le Chatelier thermo-electric pyrometer. The object of the stand is to allow of the adjustment of these tubes to proper and variable heights and angles, and to permit the positions to be changed easily and quickly. To insert a pyrometer-couple into a furnace a hole is either drilled through the back or side of the furnace, and the tube containing the thermo-couple is introduced and left almost where it drops, for the reason that it soon becomes too hot to allow of easy handling. Again, the space at the back or side of the furnace may be so small and uncomfortably hot that easy and accurate adjustment is nearly impossible.

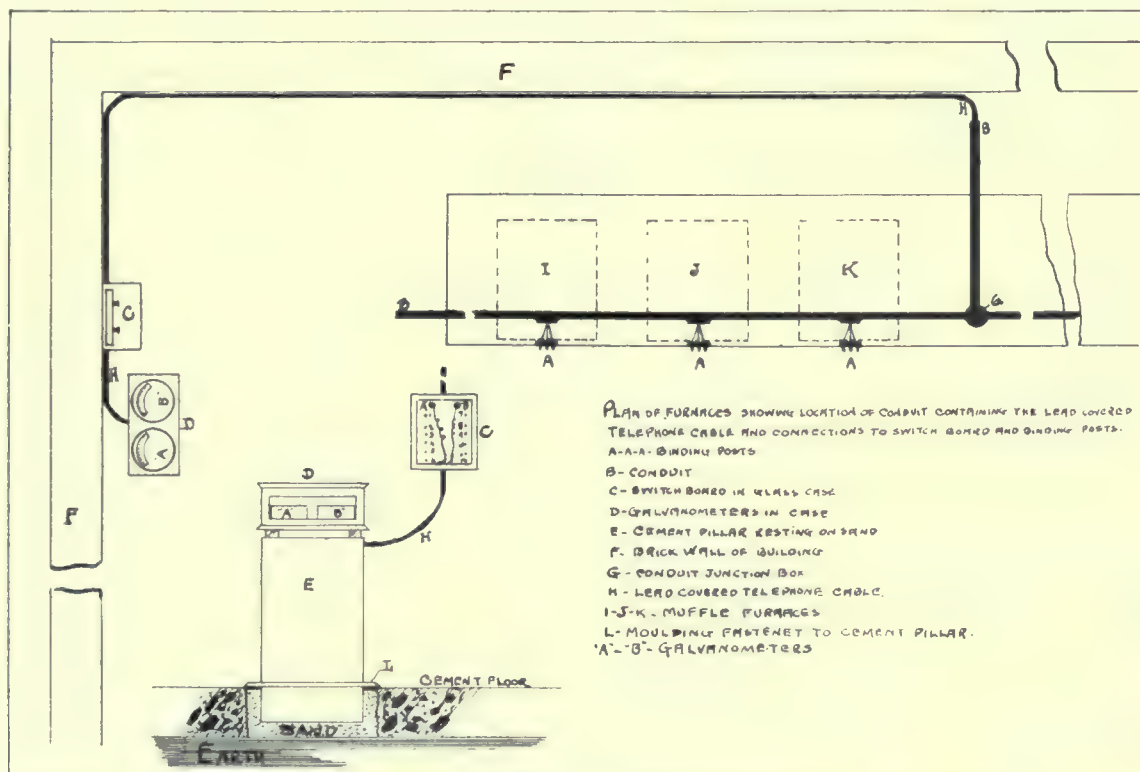

For general work the Battersea clay tubes, made by the Morgan Crucible Co., are the best, as they are not as easily corroded and broken as the fused-quartz tubes. I had some quartz tubes, $\frac{1}{2}$ -in. bore and about 3 ft. long, but wished to use a longer couple, so I took the quartz tube and placed an 18-in. Battersea clay tube of the same bore, closed at one end, next to it, then slipped a piece of porcelain combustion tubing, one inch inside diameter,

The stand is made of 1½-in. water-pipe, mounted on casters, and is heavy enough so that it cannot easily tip over. It can be adjusted to any position by being movable in three places, and it has a universal clamp which holds the clay or quartz protect-

Pyrometer Stand.

ing tube. To avoid disturbing the wires of the couple at the cold junction each time the tube is adjusted, the cooling bottle sets in a wire basket placed in such

Plan of Furnace.

over the joint, and poured the space between the combustion tubing and the quartz and clay tubes full of thin plaster of paris paste.

a way that it will move forward or back, according as the couple is moved. To overcome the necessity of leveling and adjusting a galvanometer at each

furnace, a switch-board is used to connect the pyrometer with the galvanometer by means of three binding-posts placed at each furnace.

The furnaces are numbered from 1 to 12, and to facilitate the work two galvanometers are used. These are lettered A and B. On each one of the blocks is a binding-post A and a binding-post B, while the third is numbered according to the furnace. Thus the binding-post block of furnace No. 3 would be

o	o	o
A	3	B

The connection between the binding-posts and the switch-board is by means of a telephone cable, cased in a lead tube, and to protect this under the furnaces it is enclosed in a conduit. The switch-board is made of marble, having a plug for galvanometer A, and another for galvanometer B, and 12 holes, each bearing the number of a furnace, so that each furnace may be plugged in on either galvanometer, or on both. To insure a perfect adjustment, the galvanometers are held in a dust-proof case, mounted on a concrete pillar 1 by 2 ft. by 4 ft. high, resting in sand about one foot below the floor. The wood base merely covers the hole in the floor at the front, back, and sides, and is fastened to the pillar, so that any motion of the floor is not communicated to the galvanometers. In calibrating the couples the readings of the galvanometer are taken through the cable and switch-board, so the conditions will be the same as when in use in the furnace.

The possibility that the rock-wall of a vein acts as a dialyzer, allowing some dissolved substances to penetrate it while confining other substances to the vein, has been suggested by G. F. Becker and discussed by W. Lindgren and F. L. Ransome. E. C. Sullivan has shown experimentally: (1) That a porous silicate filtering medium similar in character to a vein-wall removes iron from ferric sulphate solution, and (2) does not remove the acid radical; (3) that the solution takes up bases from the filter; and (4) that these bases are insufficient in quantity to have removed the iron by double decomposition. The ferric oxide studied appears to have been filtered out in a state of colloidal suspension by the fine-pored silicate mass aided by films of colloidal ferric oxide and silica.

Pressure-drop of compressed air and illuminating gas flowing in pipes, as determined by Dr. Fritzsche of Dresden in 1908, is calculated by the formula

$$p = 0.0602 G^{0.852} v^{1.852} L / d^{1.269}$$

where G = weight of air or gas at the initial pressure p , in kg. per cu. metre. v = velocity of flow in metres per sec., L = length of pipe in metres, and d = internal diameter of pipe in millimetres; which expresses the drop, p , in kilograms per square centimetre.

A boiler should evaporate 15 lb. of water per pound of good clean coal.

PORTLAND CEMENT.

By JOHN L. HOWARD.

*What is known as 'portland cement' was not in the first instance the outcome of scientific research. The chemist did not have before him the problem of the attainment of a certain result by the combination of certain materials, nor, having a product, did he analyze it to determine its constituent parts and their proportions. It is rather the result of a series of discoveries in the practical operation of a business, and some of these were accidental in the sense that the underlying chemical reasons were not known nor understood. Rock-cements were used long before the beginning of the Christian era, but men began to understand them only about 100 years ago, and they are still striving to fathom some secrets that have not as yet been unlocked.

In the year 1756, John Smeaton, the English engineer, while seeking a more durable material for the re-construction of the Eddystone lighthouse, discovered that an impure limestone from the blue Lias formation near Aberthaw, when burned and pulverized, not only possessed the quality of setting under water, but also attained a hardness and strength far surpassing the lime mortars then known. The material was used by him in jointing the stones employed in this structure, which withstood the ravages of winds and waves for a period of 125 years. The radical departure from practice in this case consisted in discarding a mortar made from nearly pure lime-rock, and in using that from a rock made impure by a natural admixture of clay. It marked the beginning of the knowledge of hydraulic cement, and it was the ascertainment of a fact full of great commercial possibilities for commerce and of benefit for mankind; but the scientific explanation of that fact was not made until 60 years later, when Vicat, a Frenchman, demonstrated that in the process of burning, the lime combined with the silica to form silicate of lime, which is the essential basis of all hydraulic limes and cements.

Although Smeaton's discovery was the foundation of the 'natural cement' business, he seems not to have personally profited by it, for 40 years later one Parker obtained an English patent for a product which must have been similar to Smeaton's, made from the nodules of the London clay formation. Through this patent the 'natural cement' industry was launched.

In 1810 a man by the name of Dobbs obtained a patent for producing a cement, not by the use of a natural rock but from a mixture of certain proportions of carbonate of lime and clay. Here we have the first historical reference to artificial cement made by the blending of raw materials; but this and some subsequent English patents provided that none of the substances should be vitrified.

In 1824 John Aspdin discovered that there was a distinct advantage in burning the mixed raw materials to the point of incipient vitrification, and the patent granted to him covered that feature. He

*A paper read before the Berkeley Club, March 4, 1909. By courtesy of the author.

called his product 'portland cement', because of its resemblance to the English portland sandstone, but the word 'portland' when used in this connection has no other signification. In these patents exist the bases upon which both natural and artificial portland cements have since been made, but at the outset in England it required many years for the new product to overcome conservatism and indurated prejudice.

Antedating Aspdin's English patent, natural cement was made as early as 1818 in New York, and it was used in construction on the Erie canal. Subsequently, as suitable deposits were discovered, cement mills were established in the New England, Middle, Southern and Western States. The first portland cement works were built in this country in 1875 by Benjamin Saylor, and in the now celebrated Lehigh region of Pennsylvania. Since then, and especially during the last decade, the business of manufacture has extended to the westernmost limits of the United States and Canada. Its development during recent years has probably exceeded that of any other business in the world, for besides the progress made in Europe, this statement finds verification in the official statistics of the United States, which show that the production of portland cement increased from 3,000,000 bbl. in 1897 to 48,000,000 in 1908. In fact, the productive capacity was so stimulated during the long period of prosperity prior to 1907, when expenditures in railroad and in other lines of constructive activity had set a new high-water mark, that it now exceeds the demand, which fell off during 1908 to the extent of 8,000,000 bbl. The industry has experienced a year of such actual loss that to prevent ruin to many enterprises, a serious and gigantic movement is now on foot in the Eastern States to remedy the evils incident to over-production. The possibilities in the development of the manufacture and in the uses of portland cement are scarcely conceivable, when one considers the strides of improvement in the making, the readiness with which the product lends itself as a substitute for other structural materials, and the widening uses to which the ingenuity of man is pushing its adaptation for constructive purposes. It is now the rival of stone, brick, and timber. The areas at present known and available containing timber and iron are the subject of much study and speculation. Their contents have been approximately determined, their annual rate of exhaustion is known, and the time limit of yield has been calculated. Certain it is, that, as this limit of life is approached, the value of lumber and steel will greatly increase, and the next generation in this country will face price-conditions not now conceivable.

Notwithstanding the recent tendency to depart from the use of perishable timber in important structural work, its consumption in the United States is now greater than at any former period, reaching the highest point in 1906, with a record of 40 billions of feet board measure. So, too, the statisticians have calculated the probable life of the iron ore deposits, and it is estimated that the duration of the high-grade supply will not be more than 50 years. But

Nature has been so bountiful in the widespread distribution of minerals, that the multiplication of cement-producing plants will continue with the increasing demand for the product, and with this multiplication there will as surely follow the study and the use of every possible contrivance for the lowering of the cost. It is the ability to control the supply of raw material in the limited and favored areas containing timber and iron ore that makes possible the gigantic lumber and steel combinations, but limestone and clay deposits are so large and plentiful, and so widely scattered, as to make it inconceivable that they ever can or will come under monopolistic control, and therefore a strict monopoly of the cement business is scarcely within the limits of probability.

What is portland cement? Governments and technical societies have found it necessary to give precise definitions. They differ in minor particulars, but in substance it is described as a product formed by the fusion of only clay and lime. It is allowable to add not exceeding 2% of some substance to retard the setting, but beyond this, all additions and substitutions are to be regarded as adulterations. To make this definition more clear, the best known brands have been analyzed, and the tabulated results show that they contain:

	%
Lime	60 to 65
Silica	20 to 25
Alumina	1 to 8
Magnesia	1 to 3
Iron	1 to 4

Experience has taught the manufacturers that a good and uniform product depends on keeping within these ranges of composition. The lime is found in deposits of chalk, marl, and both pure and impure limestone. The silica is obtained from beds of shale and clay which contain in combination the alumina, magnesia, and iron. When the clay and lime are found combined as a natural deposit, and without being first ground and chemically corrected, they are calcined and pulverized, and the product is known as 'natural cement,' but the quality is neither high nor uniform, although it must be said there are examples of very durable work made with that material. The American 'rosendale' and many of the Belgian cements are of this character. But where the raw materials are assembled and adjusted to set rules of proportions, pulverized, burned, and re-ground, the product is termed artificial or portland cement. These are the distinctions recognized in the trade.

In the earlier history of the industry, and indeed until quite recently, portland cement was made by what was known as the wet process. In this the raw materials were mixed in water, and the 'slurry' was run into settling ponds or vats. After the sedimentation had taken place, the clear water was run off, and the remaining moisture was partly evaporated by natural or artificial heat. The cake, sometimes pressed, was then stacked in alternate layers with coke, in vertical kilns. When the kilns had been fired sufficiently long, they were cooled and drawn, and the properly burned 'clinker' was sent to the

mills for grinding into cement. This process was intermittent, laborious, and expensive, and the product was not uniform in quality.

But there came a revolution in method due to the introduction of the dry process, which met with the head-shakings of doubt and the opposition that are usual when established practice faces untried ideas. The new process being continuous and more economical, it prevailed, and compelled an abandonment of the older methods. Before starting a cement industry it must be assumed that there has been found abundant limestone and clay. To avoid mistakes, the prudent investor will submit the raw materials to chemical analysis, to determine their suitability for cement-making. He will also have practical tests made to ascertain the quality of product that may be made from it. If the results are satisfactory, the problem is then submitted to the cement engineer, who fixes the site for the plant, designs the buildings and accessories, selects the modern types of machines for each part of the process, and carries construction to completion.

In actual manufacture the lime rock is crushed at the quarry and this and the clay from the bank are transported to the mill, and deposited separately in storage bins. Each is thoroughly dried and then roughly ground in a ball-mill, that is, a rotating cylinder partly filled with steel balls; and the dried materials are there reduced to the condition of coarse sand, and stored separately.

At this point occurs the first critical work of the chemist in the laboratory. Variations of moisture having been eliminated, he must constantly analyze these dried materials, and converting terms of percentage into terms of weight, calculate such a mixture as will conform to the proportions needed to furnish the desired product. Carelessness at this stage is fatal to good quality. After this first reduction the mixture is passed into tube-mills, which are likewise rotating cylinders partly filled with steel balls and flint pebbles, and in them the grinding is completed, and the mixture is reduced to the condition of fine flour.

The intimacy of mixture and the fineness are essential to the success of the next process, which is burning. This is performed in what are known as rotary kilns, which are slowly rotating cylinders, some as long as 150 by 8 ft. diam., lined with thick fire-clay blocks, and slightly inclined from rear to the front. The pulverized raw material is automatically fed in a regulated quantity into the rear of the kiln, and in its slow progress toward the front, it passes into a constantly increasing temperature due to the combustion of pulverized coal, crude oil, or natural gas. The heat first dissipates the residual moisture, then the carbonic acid gas, and lastly it fuses the lime with the silica and other minerals to form a new compound, an alumina-silicate of lime.

This red-hot semi-fused product, in the shape of coarse sand, and of lumps varying in size, is ejected from the kiln, and in this form it is known as 'clinker.' The theory, and the effort, is that all the lime and all the silica should be made to combine, and the previous fine-grinding and thorough mixture

were for the promotion of this union, but in fact this completeness of fusion is not realized, neither is uniformity of burning accomplished. For although the quantity of material fed to the kilns is automatically regulated, and the speed of rotation is mechanically governed, the burning is not under exact or instrumental control. The eye directs the judgment of the skilled attendant, who, watching the incandescent flame through smoked glasses, cannot detect variations at high temperatures. Sometimes clinker is over-burned when the vitrification is carried too far, in which case the product has no value as cement; at others it is underburned, where the fusion has not been carried far enough, but in either case it is not possible to make any separation of the bad from the good clinker, all must go together, and if there be enough of the bad material it will be reflected in the quality of the final product. It was the invention of the rotary kiln that worked the revolution in the process, and permitted the manufacturers to use the continuous dry system.

The clinker is next subjected to the influence of cold air blown through a cooler, sprayed with water, and stored under cover or in the open for seasoning through exposure to the atmosphere. This has the effect of decrepitating the lumps, and if uncombined or free oxide of lime be present, it is converted into the hydrated form, and thus rendered inert and harmless. The seasoning process being completed, the clinker is passed through ball and tube-mills, which complete the grinding, and thence, as finished cement, it is conveyed to the stock-house for storage and further seasoning prior to packing for shipment.

In this brief and general description it will have been noticed that a cement mill is a huge laboratory for the manufacture on a large commercial scale of the alumino-silicate of lime, and it will be difficult to find an industry in which the skill of the engineer has been more effectively used for the elimination of human labor. It requires approximately 700 lb. of raw material to produce a barrel of 400 lb. of cement, so that in a mill of 5000 bbl. capacity, 1750 tons of lime rock and clay must be treated daily, and yet so complete are the mechanical arrangements that this volume of material is not touched by hand from the time it leaves the quarry until it is delivered into the sacks ready for sewing. It may also have been observed that the quality is largely dependent upon the chemist. Day and night he is at work in the laboratory on periodical chemical tests of raw material; for unless that be kept in close conformity with a set standard, the resultant product will not meet the requirements of the subsequent physical testing to which it is constantly subjected. So important is this, that the National, State, and municipal governments, as well as the technical societies, have prescribed, not only standard rules for making physical tests, but also the standard results that must be obtained from those tests, and cements that do not meet the specifications of the American Society of Civil Engineers, for example, are properly rejected. The manufacturers of cement have this knowledge, and for the most part follow the requirements in their laboratory practice. This being so,

there is no reason excepting cupidity for the shipment of cement, which shall be found wanting when weighed in this balance. Regardless of brand, name, and reputation, all cement should be tested, and this necessity increases with the importance of the work. Faulty cement should be rejected, and its use should be officially prohibited. Through ignorance, carelessness, or dishonesty, good cement will often yield poor results. It is the smallest, but the most important of the constituents of concrete, but where there has been an utter disregard of proportions, or of the character of the rock, gravel, sand, or water with which it is associated, good concrete cannot be made, and if not made, the fault is laid at the door of the cement, which has not been given the 'square deal.' On the part of the investigators the logic of their formula is, that in concrete certain results should be yielded by the cement.

A long series of tests made with well known brands of good reputation have yielded certain results. Therefore any cements, which upon being tested in the same manner will give equal results, may similarly be considered good, and as meeting the specifications.

The routine tests are:

Soundness.—For the detection of free or uncombined lime; which when present in important quantity will cause expansion and destroy the constancy of volume of the work made from the cement. Chemical analysis will not distinguish between the lime which is free, and that which is combined. A severe test is to fill a tube with paste, and the expansion of the free lime will cause the glass to crack. The ordinary method is to make pats of neat cement on glass, and expose them to vapor and water-baths, which will cause unsound cement to display cracks and distortions. The causes may be the disproportions, the lack of fineness, or the incompleteness of the mixtures, of raw material, or it may be improper fusion. The remedy lies partly in the seasoning of the clinker and the cement in order to render harmless the oxide of lime.

Fineness.—It is required that no less than 92% by weight shall pass through a 100-mesh sieve, nor less than 75% through one of 200-mesh. Chemists do not yet know at what point in fineness the cement begins to develop cementitious value. They do know that the particles which fail to pass through the sieves will not of themselves set; and they know that if these particles be re-ground they will harden. Some theorists contend that only about 10% of the material is of the fineness to have any value, and that the balance is useful only as so much sand to fill the voids. The Germans were the first to discover the effect of fineness on quality, and the English manufacturers were compelled to follow their practice in this regard.

Tensile Strength.—This test is made by the breaking of briquettes formed in standard molds where the mid-cross section is exactly one square inch. Neat cement paste, and that made by a mixture of one part of cement with three parts of standard quartz-sand, is forced by finger-pressure into molds, and when released is kept first in air and afterward

in water, and a pair of briquettes is broken at 1, 7, and 28 days, and also at longer intervals. The machine used exerts a constantly increasing power to pull the briquette apart, and when the fracture occurs, the amount of strain exerted is indicated. The specifications require that the tensile strength shall be within the following limits:

	Neat, lb.	¾ sand, lb.
24 hours	150 to 200
7 days	450 to 500	150 to 200
28 days	550 to 650	200 to 300

It is also required that with age there shall be no retrogression in strength.

Compressive Strength.—Although for the most part concrete as a weight-sustaining body is subject to compressive strains, this test is not currently made because of the cost and cumbersomeness of the apparatus, and the consumption of time, it being assumed that the compressive strength is equal to about eight to ten times that shown by the tensile tests.

In concluding this brief review of the history, processes, and quality determinations, it may be said that after all these years of experience and research, there is much about this sensitive and delicate product that is mysterious. There is no certain knowledge as to the functions performed by the various ingredients that enter into its composition, nor precisely what occurs in the process of setting, nor what degree of fineness is necessary to make it entirely valuable, nor why with age weak cements will sometimes increase, and at other times strong cements will diminish in tensile strength, but it is almost certain that their secrets will be revealed, and that human ingenuity will enable the maker to have as much control over the product as the metallurgical chemist now possesses over the quality of steel. Ultimately cements will be made to exactly meet every special need either above or beneath the water or the earth.

Throughout historic time the styles of architecture and the modes of construction have been determined by the character of the available structural material. The early Egyptians living at the mouth of the Nile, used bundles of reeds, placed vertically and horizontally, and plastered with mud. This was the use of the beam-principle. Later through the dispersion of population they came in contact with the limestones and granites of the Upper Nile, and these were substituted, but the same beam-construction was employed, which found its highest expression in the temples of worship. The Assyrians at first occupied the treeless and stoneless alluvial plains at the mouths of the Tigris and Euphrates, had recourse to the available clay which they converted into sun-dried and vitrified bricks, and these were structurally employed in styles suitable to their character. There is some evidence, however, that the use of these small units enabled them to construct the arched vault. Later the discoveries of stone permitted its substitution as a building material, and brought about a change in style and in structural methods. Through the employment of the Pentelican marble the Greeks continued the use of the column

and beam-principle, but the Romans were the first to combine the column and the arch, and this is said to have been due to the use of the plastic material known as roman cement, not cement in the sense we now understand it, but a mixture of lime-putty, quarry-chips, and a sharp volcanic sand obtained on the shore of the bay of Naples. This mixture was deposited within wooden forms for the making of arches and walls, precisely as cement is similarly used today. It had the property of hardening, and was faced with other material. They were, however, prodigal in its use, as for instance the Roman Pantheon, with a diameter and height of 142 ft., has walls 20 ft. thick. The spread in the use of the Roman arch was owing to the constructive activity of the Romans throughout their conquered provinces, and the modifications of it may be traced during the early centuries until the Medieval Gothic cathedrals rose in stone to attest the skill and boldness of design, the marvelous beauty of execution, and the religious zeal that prompted it all. And so in all times brick, stone, timber, and steel, alone and in combination, according to availability and cost, have locally determined the constructive materials and their methods of application.

But within the present generation there has been made an important discovery in physics, namely, that steel and cement-concrete expand and contract in the same ratio. The application of this fact meant that when steel bars were embedded in concrete, there was an adhesion to them of the cement, and they became not separate strengthening units, but were incorporated and made part of the mass, thereby imparting to it the tensile strength which is lacking in the concrete itself. This has made possible the construction of buildings that are practically monolithic, where foundations, walls, partitions, floors, and roofs are armored concrete, from which there is eliminated all other structural material, save the metal used in the doors and windows.

In the process of hardening, the theory is that crystallization occurs and proceeds in all directions, and thus, in this artificial stone, homogeneity exists instead of the lamination that is common to many varieties of building rock. Cement concrete possesses undoubted fire-resisting qualities, and during the period of its use it has shown itself capable of withstanding the action of the waves and of the elements. It is possible to make it both damp and waterproof. Those deft artificers, the Italians, are making it serve the highest purposes of building ornamentation, as well as extending it into every possible channel of common utility. They have constructed and are using harbor barges, or lighters, capable of carrying as much as 250 tons of cargo.

The railroads are experimenting with armored cement ties, which as yet have not been made to meet all the required conditions. In the irrigation schemes the Government has found it to be effective in the construction of reservoirs and dams, and as lining in the miles of canals and ditches to prevent loss by seepage. It lends itself to the construction of telegraph poles, wharf-piles, fence-posts, and in many other directions as an imperishable substitute for

wood. Its use is becoming general in the erection of industrial establishments and of tall chimneys, and with it the engineers have been enabled to modify the form of bridge-arches, for nothing is more durable, and no designs of bridges are more graceful and pleasing to the eye than those of modern construction through the use of steel reinforcement in cement-concrete. It would serve no good purpose to continue the enumeration of its uses and substitutions. In the past the changes in structural styles and methods were slower than the reading of history would seem to indicate. But the marvelous strides made in so few years by this relatively new material leads to the reflection, that in this department of activity we have passed the beginning of another era of change, and that future generations may mark this epoch just as those of our day have noted the revolutions in the past.

Laboratory determinations of volatile matter in coal serve as a more or less valuable indication of the adaptability of the coal to industrial uses either for combustion, destructive distillation, or gasification. The method for this determination is, however, arbitrary and does not duplicate closely that of any industrial operation. Furthermore, the results by the laboratory method are sensitive to varying conditions and the influence of such variation on the character of the volatile products has not heretofore been the subject of extended study. The importance of the rôle played by the volatile matter in industrial applications of fuel is generally recognized. There are more heat units in the volatile matter in proportion to its weight than in the fixed residue. Pittsburg coal of 30% volatile matter and 7 ash has 36% of its heat-value in the volatile matter. When coal is fired under a boiler either by hand or mechanically, it first undergoes a process of distillation, and both the quantity and quality of the volatile products and the relative ease of their liberation, are concerned largely in the boiler-efficiency and the production of smoke. The low-temperature gases given off are high in illuminants and the higher homologues of methane, and low in hydrogen. At about 500° C. the tarry products are evolved in greatest quantity, as well as the illuminants. The amount of CO steadily increases with rise in temperature; and the same is true of CO₂. The smokeless character of a coal seems to be closely related to the presence of considerable hydrogen in the volatile constituents evolved at low temperatures.

Efficiency of a dryer is the theoretical heat required to do the drying, less the loss of heat. These losses are but three, the greatest being the heat carried out by the exhaust or waste gases; this may be as great as 40% of the total heat from the fuel, or, with a properly designed dryer, be as small as 8%. The next greatest loss is by radiation from shell or walls. This may be as high as 25%, or as low as 4. The smallest loss is due to unnecessary heat carried away by the dried material. This may amount, under certain conditions, to as much as 25% or as low as nothing. Whatever loss there is, however, is generally due to careless operation.

COMPANY REPORTS.

OOREGUM GOLD.

The report of the Ooregum Gold Mining Co. of India, Ltd., for 1908 shows it to be in good condition. The Ooregum mine is in the Mysore district and is under the management of John Taylor & Sons, with R. H. P. Bullen as resident superintendent. Within the year 121,886 tons of ore were crushed with a production of 73,871 oz. gold. There was a further saving of 12,131 oz. from the cyanidation of 108,869 tons of tailing. In addition 250 oz. were reclaimed from an old mill which was dismantled. This was an increase of 12,690 oz. over the preceding year. The total dividends for the year amounted to 32½% on the preferred and 22½% on the common shares. In addition £25,841 9s. 1d. was paid on capital account, £20,000 appropriated on the Bullen shaft account, £7624 10s. 11d. set aside for depreciation, and £3754 for income tax. The profit and loss account showed a balance of £4455 10s. 8d., as against £3168 15s. 7d. at the end of 1907. Ore-reserves are estimated to have been increased 10,293 tons and to now amount to 154,281. The yield per ton milled was 11 dwt. 0.18 gr., and per ton cyanided 1 dwt. 21.25 gr., an improvement of 1 dwt. 22.93 gr. Experiments are being made with the Ridgway filter in a slime-plant.

MOUNT BOPPY.

The mines of the Mount Boppy Gold Mining Co., Ltd., are situated in New South Wales and are under the management of John Taylor & Sons. The production for 1908 amounted to 34,136 oz. fine gold, equivalent to 9 dwt. 19.57 gr. per ton crushed. The total dividends were £57,475, equivalent to 47½%. The ore treated was 6782 tons less than in 1907, but the recovery came to 2534 oz. more. James Negus, the manager, computes the payable ore-reserves to be 126,850 tons. Within the year the total tonnage crushed was 69,715; tailing cyanided 48,558; slime 27,540; concentrate sold 255; total fine gold production, 34,136 oz. The vein varies from 5 to 60 ft. in width, and consists of quartz traversing slate. It carries gold in extremely fine state of division with galena and blende. Oxidation has taken place to nearly 400 ft. in depth. Development extends to 500 ft. The average yield per ton of ore crushed in 1908 was 11 dwt. 8.25 gr. fine gold. Since milling began in 1901, 358,577 tons have been crushed. The total amount realized has been £733,811 10s. 7d., of which £319,757 13s. has been paid in dividends.

BANTJES CONSOLIDATED MINES, LTD.

The report at hand covers the period from the resumption of operations in August to the close of 1908. W. W. Mein, consulting engineer, reports that re-sampling of the South Reef in the eastern section, completed in February 1909, showed the presence of 150,660 tons of payable ore with an average value of 8.7 dwt. No sampling has yet been done on the other reefs in the property, but the results are believed to be sufficient to warrant vigorous prosecution of the work. By the re-organization £140,000 became available. With this liabilities have been liquidated and the mine is to be re-opened. A 35-stamp mill is being built and is expected to be ready for operation by May. The proceeds from milling operations are to be used for the next year in further development.

VOGELSTRUIS CONSOLIDATED DEEP, LTD.

The Vogelstruis was re-organized in August last year, with a reduction of £294,750 in capital. It has now 299,900 shares of £1 value, of which 70,650 are held in reserve. There is £70,600 outstanding in 6% debentures and the company now has £107,513 cash on hand. The property is being re-opened, work having been begun in October. A 40-stamp mill has been ordered and is expected to be in operation in May. According to S. C. Thomson, consulting engineer, the payable ore-reserves now amount to 91,923 tons, having an average value of 8.94 pennyweights.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

CONTRACT FOR DRILLING COAL LAND.

A contract for drilling coal land stipulated for the payment of a certain price per foot up to a given depth if coal was not reached before that depth; it also stipulated for the payment of the same price if it was necessary to go to a greater depth. In an action to recover on the contract by the driller, the court held that the contractor's right to recover was not dependent on striking coal; and especially where it appeared that payments for work done had been made as though striking coal was not a condition precedent.

Western Fuel Co. v. Fuller, (Ark.) 113 Southwest. 1021, Nov., '08.

ADJACENT CLAIMS—DEVELOPMENT WORK.

Where several persons hold separate but adjacent mining claims, and work beneficial to all can best be done on one of them, under a proper agreement between the owners the development work can all be done on one and credited to the several claims, where such work constitutes a general plan or scheme for the development of the several claims. It is the rule that development may be done outside the limits of the claims, and may be credited thereon if beneficial to all the claims for which the credit is asked, provided the claims are held in common.

Hawgood v. Emery, (S. Dak.) 119 Northwest. 177, Jan., '09.

LIABILITY FOR INJURY TO EMPLOYEE.

Where a contractor was working a portion of a mine under a contract with the owner under which he mined the ore at a stated price, and the owner retained control of the mine and had the duty of inspecting and keeping the mine in safe condition, an employee of such contractor was not a trespasser, nor a mere licensee, but was said to be there by invitation of the owner, and as to him the owner must exercise ordinary care and prudence to render such mine reasonably safe.

Tennessee Coal, Iron & Railroad Co. v. Burgess, (Ala.) 47 South. 1029, Dec., '08.

WARRANTY—CONSIDERATION.

A deed purporting to convey certain real estate particularly described, recited, immediately after the description, thus: "The right and title to the surface soil thereof, with its appurtenances appertaining thereto, except the mining privileges thereof;" and this was followed by the usual words of warranty. Under this deed it was held that no claim to the mining privileges and rights in the land could be asserted by the successors in interest of the grantor after a period of nearly 50 years, and after both grantor and grantee were dead. The provision as to the mining privileges was construed as a mere limitation on the covenant of warranty, and not as a reservation to the grantor of the mining rights in the land.

Towns v. Brown, (Ky.) 114 Southwest. 773, Dec., '08.

FORFEITURE OF CLAIM—DEVELOPMENT WORK.

One of two partners or owners in common of two or more claims cannot prevent a forfeiture of rights by a co-partner by showing that he had performed work on adjacent claims, beneficial to the claims in litigation, he being the sole owner of a part of such adjacent claims, and the owner in common with third persons of the other claims on which the work was done, if no agreement exists between them for doing such work, or unless a sufficient showing can be made that the work was part of a general plan or scheme for the development of the claims owned by such partners in connection with the claims on which the work was done. The reason is that one partner cannot, in the absence of an agreement, perform work on property in which his co-partner is not interested, and hold his co-partner liable therefor.

Hawgood v. Emery, (S. Dak.) 119 Northwest. 177, Jan., '09.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

HANDBOOK ON AMERICAN MINING LAW. By Geo. P. Costigan, Jr. 8vo., pp. 765, index. West Publishing Co., St. Paul, 1908. Price \$3.75.

This work is a valuable addition to the literature of mining jurisprudence. The author has entered into the spirit of Western mining law and his treatment of the subject gives evidence of being the result of honest and painstaking labor. One can hardly agree with Costigan in his belief that *Belk v. Meagher* (104 U. S., 285) "was wrongly decided," and that *Lavagnino v. Uhlig* (198 U. S., 443), which is inconsistent with the former case, is the better doctrine of the two. The recent case of *Farrell v. Lockhart* (210 U. S., 142) has had the effect of re-instating the doctrine of *Belk v. Meagher*, and again giving full force and effect to the rule that a re-location made while a valid and subsisting senior location covers the ground is void and, in order to secure any right to the senior claim, a person who intends to re-locate must wait until the senior claim has been abandoned or forfeited. (See discussions of this question in *MINING AND SCIENTIFIC PRESS*, Vol 94, pp. 212, 695, and 751.) Nor are his definitions of 'shaft' as being "a perpendicular excavation," and of 'chimney' or 'chute' of ore as being "a perpendicular enlargement of the orebody," strictly accurate. It is easier, however, to tear down than to build up, and it would not be fair to Costigan to leave one with any other idea than that he has produced a comprehensive and up-to-date work on a subject that is highly specialized. The book is intended for students as well as for practitioners, and it should be found on the shelves of every person interested in the subject of mining law.

HEAT ENERGY AND FUELS. PYROMETRY, ANALYSIS OF FUELS, AND MANUFACTURE OF CHARCOAL, COKE, AND FUEL GASES. By Hanns v. Jüptner, translated by Oskar Nagel. 8vo., pp. 306, Ill., index. McGraw Publishing Co., New York, 1908. Price \$3.

The work of so distinguished a man as Prof. Hanns v. Jüptner is certain to be solid, and examination shows that no general dissertation has been relied upon, after the manner of those who are mere makers of books. As a discussion of methods of heat-measurement this book is one of the best condensed statements we have seen, and the same will apply to the extensive chapter on calorimetry. The book is one adapted in this particular for general use and for purposes of instruction. Half of the treatise is taken up with a discussion of various fuels and methods of utilization. There are chapters on the different kinds of coal, peat, briquetted fuels, liquid fuels, producer gas, water gas, and blast-furnace gases. The best of these deal with coal and producer-gas. The contribution to knowledge of liquid fuels is so trivial that it might as well have been omitted. In fact, the book is of value especially for its discussion of estimating heat-values of fuels by pyrometry and calorimetry.

ENGINEERING INDEX. Annual for 1908. 8vo., 137 pp. New York, Engineering Magazine, 1909.

This represents the continuation of work started by J. B. Johnson in 1884 and followed since 1895 by the *Engineering Magazine*. It is the third annual volume. The attempt is made to cover the whole engineering field, with the result that while over 8000 entries are made there are, for example, only six for gold and silver in Colorado, and one of each for California and Alaska. Australian zinc is dismissed with two titles, and Mexican with one. Wisconsin, under this subject, receives no notice. Any one familiar with the literature of the subject in 1908 will recognize that the naming titles are not only too few, but poorly chosen. Inconsequent articles are allowed to crowd out other of better import. Presumably the other portions of the index are better done, as they are fuller, but for mining engineers, at least, the book is important mainly as a guide

to related subjects. The work is evidently too large to be properly carried out with the means employed.

ACCIDENTS AND EMERGENCIES: A MANUAL OF THE TREATMENT OF SURGICAL AND MEDICAL EMERGENCIES IN THE ABSENCE OF A PHYSICIAN. By Charles W. Dulles, M. D. 7th ed., 8vo., pp. 205, ill., index. P. Blakiston's Son & Co., Philadelphia, 1909. Price \$1.

One important function of every mine manager is to serve as physician and surgeon in emergencies; every man on the frontier of civilization needs to prepare himself to render service of that kind. Indeed the knowledge of effective first-aid to sufferers is useful to every man, whatever his environment. The little manual by Dr. Dulles is one of the most comprehensive of its class; written in lucid simple language, with instructions given in that definite form which is essential for application by laymen. The illustrations are most helpful, and the key to the subject-matter by table of contents and index renders it instantly serviceable. It should constitute part of the equipment of every miner.

PRACTICAL CALCULATION OF TRANSMISSION LINES, FOR DISTRIBUTION OF DIRECT AND ALTERNATING CURRENTS BY MEANS OF OVERHEAD, UNDERGROUND, AND INTERIOR WIRES FOR PURPOSES OF LIGHT, POWER, AND TRACTION. By L. W. Rosenthal. 8vo., pp. 93. McGraw Publishing Co., New York, 1909. Price \$2.

There is no waste space in this volume. It is a calculator's assistant, pure and simple. The elements of the problems in current transmission are all given, but in the briefest form. For example, in the first chapter the sub-headings are: properties of conductors, discussing both copper and aluminum, current-carrying capacity, parallel resistance of wires, together with tables embracing ampere-feet per volt drop and current-carrying capacity, and so forth. The book is made up of formulas, tables, and practical examples.

LAW AND BUSINESS OF ENGINEERING AND CONTRACTING. By Charles Evan Fowler. 8vo., pp. 162, index. McGraw Publishing Co., New York, 1909. Price \$2.50.

The title of Mr. Fowler's book is misleading, very little space being devoted to legal matters. As an engineer of wide experience he has accumulated valuable information on the drawing of contracts, in the making of specifications, estimates for materials, inspection, and the like. These are the subjects treated, and within the limits of a small volume they are exceptionally well set forth. The example of specifications of structures chosen is for roofs and buildings, which will appeal to a wide range of engineers. The methods of inspection for structural steel is given in outline, sufficient to guide an engineer in making contracts for such supplies. Cement testing is given in detail. It is a useful work.

THE MINE INVESTOR'S GUIDE. By Floyd Davis. Small 8vo., pp. 168, ill., index. Western Correspondence School, Des Moines, Iowa, 1909. Price \$1.50.

Elementary disquisitions on mining are usually addressed to prospectors; this is a bow to the capitalist—we can scarcely call it a 'tip.' The random shots at miscellaneous, geological, mining, and metallurgical matters could serve only to give a clouded view. Elucidation, there is none. We cannot discover a useful function which the book might perform.

BIBLIOGRAPHY OF THE GEOLOGY, MINERALOGY, AND PALEONTOLOGY OF BRAZIL. By J. C. Branner. Bull. Geol. Soc. Amer., Vol. 20, pp. 132.

MINERALS OF ARIZONA. By W. P. Blake, Territorial Geologist. 8vo., 63 pp. Tucson, 1909.

MINING AND METALLURGICAL PATENTS.

CONVEYER-SPIRAL.—No. 915,702. Wilhelm Schroer, Dahlebrück, Germany.

A conveyer spiral consisting of a screw blade extending around a shaft for more than a full pitch and of a spiral base integral therewith in T-shape adapted to fit over a shaft, and having only half the thickness of that of the screw blade.

ORE-SMELTER.—No. 916,176. Ezra A. Mathers, Philadelphia, Pennsylvania.

A smelter comprising a furnace, a rotary roaster directly above and in the same casing with said furnace, a smelter arranged adjacent to the casing containing said furnace and roaster and in a single structure therewith, said structure being formed with an ore-conduit leading from said roaster into said smelter, said several parts being arranged to co-operate continuously, substantially as set forth.

ATMOSPHERIC STAMP.—No. 915,362. Charles H. Krause, Keweenaw Bay, Michigan.

In an atmospheric stamp the combination of a cylinder, a mechanically operated piston and an atmospheric piston in the cylinder, a pestle connected to the atmospheric piston, an inlet and an exhaust for the cylinder, an oscillating valve and a check valve controlling the inlet port, means for mechanically operating the oscillating valve, and an adjust-

able check valve controlling the exhaust port, the exhaust port leading from the cylinder near the end of the stroke of the atmospheric piston during which the atmospheric piston leads, whereby during the first part of such stroke the air under pressure between the pistons may be retained and raised to a high pressure to insure a heavy blow by the pestle.

GASOLINE-OPERATING ROCK-DRILLING ENGINE.—No. 915,320. Rolland S. Trott, Denver, Colorado.

In a gas explosion operated rock-drilling engine, a cylinder, a crank chamber adjacent to said cylinder, apertured lugs at the rear end of said crank chamber, a piston mounted to reciprocate in said cylinder, having thimbles adapted to enter said apertured lugs, and thus cushion the rear stroke of the piston, a swinging plate on said piston cushioned at one end within one of said thimbles, a fixed plate adjacent to the swinging plate, and a fly wheel having a crank pin adapted to move between said fixed and swinging plates.

SMELTING-FURNACE.—No. 915,192. August Koch, Hanover-List, Germany.

An oil heated smelting furnace comprising a plurality of rotatable chambers adapted to operate alternately as smelting or as preliminary heating chambers, and a fuel vaporizing and air heating compartment connecting said smelting and said preliminary heating chambers causing the combustion gases to first pass directly from said smelting chamber into said heating compartment, and thence directly to the other chamber used at the time as preliminary heating chamber for the material to be subsequently smelted.

WATER ATTACHMENT FOR DRILL-STEELS.—No. 915,230. James H. Sinclair and Guy D. Neill, Denver, Colorado.

In a water attachment for rock drills, the combination with the drill steel having a central longitudinal passage open at the forward or cutting extremity of the steel, its rear extremity being closed, the steel having a transverse orifice communicating with the longitudinal opening, and a drill steel holder comprising a base having a threaded opening and two outwardly projecting hook-shaped members projecting from opposite sides of the base, their hook-shaped extremities projecting over the drill steel in opposite directions, and a nozzle screwed into the opening in the base of the holder and arranged to engage the drill steel whereby its passage is caused to register with the transverse orifice of the drill steel, substantially as described.

New High-Pressure Hose.

The Mulconroy Co., Philadelphia, is the manufacturer of a new type of high-pressure hose which is made to withstand working pressures of air or water up to 10,000 lb. per square inch. This hose, because of its peculiar construction, is claimed to possess distinct advantages for certain classes of service. It is covered by a metallic surface composed of fine galvanized-iron wires, arranged in strands of seven wires each. Two series of strands are used, one forming the right-hand, and the other the left-hand spirals around the hose. Each strand passes alternately over and under the strands wound opposite to its own direction. The pitch of the spirals on the usual size of hose is about $1\frac{3}{4}$ in., giving ten strands to each series. The wires in each strand lie flat, side by side, so that a smoothly woven, flexible, metallic

covering is formed around the inner tube. The inner tube is of the ordinary rubber and fabric construction. The metallic covering relieves the inner tube from the severe tensile strain due to high internal pressure, and also protects it from wear and abrasion. The $\frac{1}{2}$ -in. hose may be bent to a 3-in. circle without kinking. The strength afforded by the covering makes it possible to reduce the number of plies in the inner tube, and for this reason the metallic hose can be manufactured at a cost slightly less than that for high-pressure hose with a fibrous covering. With a single covering the hose can be used for working pressures up to 1000 lb. per square inch, and for higher pressures additional layers of metallic covering are added.

New Hopper Cooling Plan for Gasoline Engines.

The well known principle of maintaining a moderate temperature on gasoline engines has heretofore been through the use of a large water tank or pump, which has the disadvantage of increasing the weight, or being cumbersome, and of requiring a great deal of water for cooling. It is necessary in a gasoline engine to have a circulation of

water around the cylinder to prevent overheating and to maintain a moderate temperature, so as to avoid ignition of the fuel before the proper time; this is why the water is used for cooling.

The new hopper principle consists of making a cast-iron hopper in box form, placing it over the cylinder, and holding the water directly over the cylinder for cooling purposes. The principle of the teakettle again comes into effect. The open top of the cylinder and the open hopper permit evapo-

ration; the steam condenses quickly and comes in contact with the open air immediately; consequently water exposed to the open air cools 20 to 30 times faster than water enclosed in a jacket. For that reason a hopper-cooled engine can be cooled with from 20 to 30 times less water than is used with the average engine using a water tank. It reduces the weight of the equipment, saves the water, avoids draining or handling a large amount of water in cold weather, and consequently avoids the usual danger of freezing. The cut herewith shows a Witte hopper-cooled gasoline engine, made by the Witte Iron Works Co., Kansas City, Missouri, which illustrates the simplicity of the hopper-cooling plan. In this case the hopper is built separate from the cylinder, so that it can be removed. A plate will be furnished in exchange for the hopper any time a user may desire to employ the water-tank principle in place of the hopper. The side of the hopper is also arranged for pipe-connections. The hopper-cooled engine has become popular, and is of interest to all who contemplate the use of a gasoline or kerosene engine. Whether the engine be used in a shop or for outdoor work, the principle and the convenience have the same advantages.

Self-Lubricating Stop-Cock.

The need for a simple device that combines an automatic oil-feed with a stop-cock has long been felt by users of rock-drills, coal-punchers, and air-hammers. The problem has been solved successfully by the D. D. Demarest Co. of San Francisco in the Pacific lubricating stop-cock. Without any additional wearing parts, it provides a means to lubricate the valve itself and to feed a pre-determined amount of oil to the machine every time the valve is closed and opened. There are no parts to get out of order, and as the working surface of plug and casing are always oiled, this valve will outlast several of the ordinary stop-cocks. It prevents

waste of oil which would, in the old way of oiling the machine, get into the ore, and in gold mines would cause considerable trouble and losses in amalgamation. Every drop of oil that passes through the valve is properly used in the machine, thus always providing a perfect lubrication of the interior working parts of the drill to which it is attached. The life of the machine will therefore be greatly increased and the cost of the valve saved many times. The cut shows the construction. A compression-spring and the additional live-air pressure in the oil-chamber force the valve-plug tightly into its seat, and besides preventing the leakage of air from the supply-pipe, holds the valve-plug and the handle securely in any desired position. To secure a convenient and practical connection between the machine and the supply-hose for the different makes of rock-drills, stoppers, and air-hammers, six different types in as many different sizes, have been adopted.

A NEW gold-dredging field is being worked in a quiet way in Africa. Some Australian prospectors discovered placers about two years ago at Kilva, in the northeast portion of the Congo Free State. The work is being conducted on Government account and the shipments of bullion are said to exceed \$200,000 per month.

PLANS for the work of the State Mining Bureau as announced by Mr. Lewis E. Aubury include special investigations of the petroleum and gold dredging industries. We are glad to note that sufficient funds are now available to permit of good work. There is ample field in California for the services of a large and active Bureau. That the work has not been satisfactory in the past is well known. With adequate money and with Mr. Frank W. Griffin on the Board of Trustees, an extremely valuable report on gold dredging ought to be forthcoming.

LADY BRASSEY in her 'Sunbeam Voyage' wrote that a *real* octopus is worth from a dollar to a dollar and a half. Evidently we have not the real thing at 26 Broadway, New York—only a spurious octopus. It is not worth as much as Congress thought. With jubilation the festive lawmakers placed crude oil on the free list, when lo! the multitude of pollywogs, supposed prey of the greedy cephalopod, displayed alarm, and made a great disturbance. It turns out that the pollywogs produce 89 per cent of the crude petroleum of the country. It is refreshing to find that Standard Oil does not own the country after all.

MISSOURI is still without a successful gold mine. Mr. H. A. Buchler, the capable State Geologist, finds himself unable to confirm the glowing report furnished by Mr. A. M. Beam on the property of the Boone-Baldwin Pioneer Gold Mining Co. at New Cambria. Careful sampling and assaying failed to develop even a trace of gold and silver, and only the usual coal-measures, with a little pyrite and calcite, were found in the shaft. The so-called "large section of feldspar" is an area covered with drift and showing surface boulders of greenstone and granite. Even the boulders were perverse and failed to show a trace of the precious metals. We only wish that Beam and others of his ilk were as transitory as these short-lived mines.

THE DOCTRINE of a living wage has received official sanction from Mr. Justice Higgins of the Commonwealth Court of Conciliation and Arbitration. The decision was in settlement of the Broken Hill wages dispute. In the following words he gave one of the clearest statements of the doctrine we have seen: "The first condition in the

settlement of this dispute as to wages is that at the very least a living wage should be secured to the employees. I can not conceive of any such industrial dispute as this being settled effectively, which fails to secure to the laborer enough wherewith to renew his strength and to maintain his home from day to day. In the present case all assented to the doctrine that no man ought to be asked to work for less than a living wage." As to the fundamental truth of the doctrine probably most men agree. The difficulty is in fixing the amount which constitutes a proper minimum in any given case. Shall it be Joseph Chamberlain's "three acres and a cow," John Mitchell's "six rooms and a bath," or shall it be, as the Court decided in this case, the amount the men demand?

IN AN interesting contribution to this issue on milling practice at the mines of the Pittsburg-Silver Peak Company in Nevada, Mr. Henry Hanson calls attention to the maintenance of high stamp-duty while the speed was reduced from 105 to 96 drops per minute. This result Mr. Hanson ascribes to the opportunity afforded the ore particles to settle between blows so that effective crushing might be done. The point is worthy of consideration. In the Transvaal, however, relatively high speeds are the rule, and the tendency is to increase the weight of the stamps up to 1400 and even 1600 pounds, and a stamp-duty of less than 6 tons per diem would be considered low. So important is weight in the estimation of the Rand metallurgists that the wear of shoes is compensated by extra metal.

DISMISSAL of bankruptcy proceedings against Otto Heinze & Company will have a good effect. The methods of the Heinzes are too well known to need comment; they stand for that kind of financial freebooting which assumes the dignified title of Napoleonic. The Heinze plan is directly the opposite from the Lawsonian. There is no brass-band, no alluring discourse to draw a crowd and sell tickets for the show; a growing camp suddenly finds Mr. F. Augustus Heinze in its midst; his interests ramify; at every turn in the path comes the rattle of a lawsuit. When financial difficulties threatened the existence of the firm the multitudinous relations of Mr. Heinze brought trouble to a host of innocent miners. The solvency of the house is therefore welcome, in that it means return of confidence and influx of capital, re-invigorating many paralytic enterprises.

Transportation and Coal Mining.

The constitutionality of the so-called commodities clause of the Hepburn law has been passed upon by the Supreme Court of the United States. With fine impartiality the principle contended for by the Government is affirmed at the same time that the practices of the railways are approved. Theoretically the Government wins; actually the present railroad practices remain undisturbed. Yet the decision, in confirming the main contention of the Government that it is within the constitutional powers of Congress to provide for the separation of transportation and trading, opens the way to far-reaching legislation. It seems that Congress has power to regulate

these matters, but in the first attempt has not hit the right means for doing so.

In connection with the coal business the necessity for legislation of this sort is keen. It will be remembered that for years anthracite mining was generally unprofitable. It was only after the business came under the control of a group of railroads working in close harmony, that the present satisfactory conditions were produced. It is difficult to regulate competition in the coal industry, and excessive competition has been the rule, except where regulation has come through railroads. It is easier to monopolize transportation than mining, because the larger amount of capital involved in a single working unit can be commanded by fewer people. The process of monopolization has advanced far in the anthracite region. In the bituminous fields it is less advanced. Under our anti-trust laws the coal companies are not allowed to combine for limiting production. The amount of coal available, and the ease with which it can be opened, is a constant temptation to new investment. Bituminous coal is used only as mined, and owing to seasonal variations and to the intimate relation of fuel to industry, the trade is a constantly fluctuating one. Excessive demand is followed by a glut of the market. It is also peculiarly expensive to let a coal mine lie idle. As a result of these circumstances an intense competition exists in most of the bituminous fields, and in practically all of them the mining capacity is far in excess of the average yearly demand—often indeed in excess of the maximum possible demand. Under such conditions the only possible regulation of the trade has been by the railroads, since the basis of profits in the coal business has been the ability to get a regular supply of cars and to have them withheld from competitors.

Another fact of large importance is the circumstance that the railroads are themselves large users of coal. As the largest consumers they have naturally demanded the lowest price, and as a means of getting favorable terms have either taken up mining directly, or have distributed their contracts among companies that were content to make practically all their profit from their commercial trade and to furnish coal to the railroad at a merely nominal profit in return for the assurance of a regular car-supply. In many States such profit as obtains in the coal business comes from that portion of the output which reaches the small consumer.

When the railroad itself undertakes to mine coal, either directly or by means of a subsidiary company, two motives are usually dominant. The first is the vital necessity of an adequate supply of fuel at the minimum price. Certainly no railway manager is warranted in buying coal if it can be mined with profit to his stockholders. Mining, however, eventually leads to selling coal because of the necessity of disposing of certain sizes or grades not wanted by the railroad. In the second place there is the ever-present demand for traffic, and all additional traffic either built up anew, or taken from competing roads, is, according to the law of increasing returns, of importance to the railway management even when the profit per ton carried is small. A railway manager

is always keen to induce the opening of mines and the shipping of coal because thereby a rich reward comes to his road. When Mr. E. H. Harriman took hold of the Chicago & Alton, that railway had but little coal traffic, despite the fact of its crossing excellent fields and serving a well populated territory. An active campaign resulted in the opening of many mines and a good traffic was created, partly by the simple process of taking it from other roads. Coal shipments are so important, ranging from 25 per cent of the total traffic of certain granger roads to above 80 per cent of that of coal roads, that mines may be and often are run at no profit, merely to furnish traffic to the railways. This results in cheap fuel at the industrial centres, but it robs a great industry of its independence and has an important influence in perpetuating bad business methods and increasing accidents. An operator who must keep running to meet interest on a note at bank will sell coal at any price, and will accept any terms from his men, in hopes of better times later.

It was to correct these and similar evils by absolutely divorcing transportation from mining and manufacturing, that the commodities clause was inserted in the Hepburn rate law. The anthracite carrying roads, it will be remembered, contested the law in the United States Circuit Court for the Eastern District of Pennsylvania and won, the law being held unconstitutional by Judge Gray with Judge Dallas concurring. It is on appeal from this case that the Supreme Court has just decided the law to be constitutional. As construed by the Court, however, the sole object of the clause is to prevent carriers from being associated in interest with the commodities transported at the time of transportation. The act only compels the railroads to dissociate themselves from the products they carry, and the Government's contention that the law applies to the ownership of stock and prohibits the transportation of commodities simply because they have been produced by the railroad company, is declared untenable. While the immediate effect is favorable to the railroads, and is good in that it does away with the necessity for a complete re-organization and untangling of the present complicated ownership of coal lands and roads, the decision none the less opens the way to remedial legislation. Monopoly of transportation can not be used to cure the evils of unregulated coal-production. There must be real separation of the production from transportation. The coal business must be made independent. When this is done the public will see the necessity for a regulated combination of interests and of production, but when the profits of one industry are credited to another the public is properly suspicious. Mr. John Mitchell is fundamentally right in saying that a higher average price for coal is vital, though that does not necessarily entail higher retail prices. Each great industry should be given the right to a legitimate profit, and no country can gain permanently by making so important a business as the mining and selling of coal unprofitable in itself and a mere mechanism for furnishing profitable traffic to railroads. In clearing the way to a perception of these fundamentals the opinion is of prime importance.

Regulating Copper Production.

Efforts to regulate the copper industry in America by consolidation are reported to be under way. The situation of the copper miners and smelters has been in some respects most unsatisfactory. The high prices which prevailed for a period aroused unwarranted hopes. This led to the opening of a host of new mines, and to enlargement of plant and equipment at the older properties, so that in the aggregate a potentiality far in excess of commercial requirements was created. Suspension of operations is always disastrous, not alone from the sacrifice of return on invested capital, but from deterioration of plant and injury to the mine. It means loss of money to shut down, and it also involves heavy continuing expenditure. A close association of the copper producers for mutual protection seems necessitated. The logic of circumstances points in that direction. Mr. W. E. Corey is now said to be engaged in forming a combination for this purpose. This would indicate the possibility of a cordial understanding with the United States Steel Corporation. Whether such community of interests would prove a general benefit is worthy of careful inquiry. The tactics of the Steel Corporation have been one of the serious causes of the continued financial uncertainty in this country. That corporation has been in a position to do for steel precisely what is needed for copper, namely, to fix the price for a definite period long enough to encourage a revival of construction, without which no utilization of the industrial equipment of the country, commensurate with its magnitude, is possible. The manufacturing capacity of the nation is necessarily in excess of mere maintenance of the machinery of civilization; it contemplates expansion. The productive capacity of the copper mines at the present time is also an expression of confidence in the determination of men to enlarge their activities. The opening of the new great mines of Nevada and Arizona in the dreary fog of a financial storm is evidence of inspiring faith. If this faith be not shared by the public, however, the results become detrimental. The burden of carrying great stocks of copper now rests heavily upon the shoulders of a group of capitalists. This is a condition which must cause the debit side of the copper-ledger to look unpleasant for a long time to come. The trouble has arisen largely from the uncertainty of the market, from the limitation of foresight; and the latter has been rendered the more difficult by the disturbing influence of the Steel Corporation. The independent steel producers are having a hard fight for their lives; the formation of a copper trust affiliated with the steel trust would drive the independent copper producer to bay and to ultimate surrender. To contemplate the extinction of competition in copper mining is not pleasant, but it would perhaps steady the commercial world and relieve tension. Industry in general would be promoted. There is no means for surveying the field and knowing the future requirements of trade except organization. It is a choice between a business run at haphazard with waste and loss, or regulated by economic methods.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

D'ARCY WEATHERBE is at London.
 W. E. THORNE is at Bahia, Brazil.
 JAMES DOUGLAS has gone to London.
 RALPH BAGGALEY is in San Francisco.
 J. J. ARBOTT has been visiting California.
 WILLIAM A. FARISH is in Sonora, Mexico.
 W. R. CAITHNESS is in Western Australia.
 EDWARD H. NUTTER sails for Alaska May 12.
 HENRY C. BEELER has been in Hailey, Idaho.
 F. DANVERS POWER has left London for Australia.
 J. H. CURLE is at Jumlungur, in the Punjab, India.
 A. R. LEDOUX is in the Black Hills of South Dakota.
 N. J. WELSH is at the Engineers' Club, at New York.
 BRENTON SYMONS has left London for Newfoundland.
 E. F. BURCHARD is visiting the fluorspar district of Illinois.
 EDGAR RICKARD will be at Chicago May 12, and New York May 16.
 W. H. CORBOULD is manager for the Mt. Elliott Copper Co., Queensland.
 H. W. HARDINGE has returned to New York from Tucson and Denver.
 G. H. GARREY is examining the Ojuela properties at Mapamí, Durango.
 R. K. CLANCY is operating the Santa Rosalia mine, in northern Sonora.
 T. A. RICKARD expects to be at Denver May 10, and at New York about May 22.
 CHARLES BUTTERS has returned from Nevada and expects soon to go to London.
 LOUIS JANIN, JR., has recovered from a long illness and is now in San Francisco.
 G. H. HUTTON, superintendent of dredges near Council City, has returned to Alaska.
 HENRY TAYLOR is visiting the mines of the Tasmania G. M. Co. at Beaconsfield, Tasmania.
 FRANK M. LELAND, president of the Empire Copper Co., Mackay, Idaho, is in San Francisco.

GODFREY DOVETON has been in the American Hospital at Mexico City. He is reported better.

J. O. ARMSTRONG is general manager for the Lloyd Copper Co., Ltd., at Burrago, New South Wales.

G. D. REID, who has been examining copper properties in Idaho and Oregon, has returned to Denver.

JAMES MACNAUGHTON, general manager of the Calumet & Hecla, has returned to Calumet from a visit south.

W. WRAITH, superintendent of the Washoe smelting plant, has been in San Francisco, on his return from Cananea.

J. B. MARTIN, manager for the American Mining & Development Co., at Camptonville, California, has been in San Francisco.

W. E. SIMPSON, formerly superintendent of the Zinc Corporation, Broken Hill, is adapting the Australian treatment of silver, lead, and zinc ores to the San Francisco del Oro, at Chihuahua, Mexico.

G. E. FARISH, of Denver, Colorado, and Mexico City, left Denver on May 3, to examine some properties in southern Mexico. His address for the next three months will be 2nd Bucareli, No. 35, Mexico City, Mexico.

Obituary.

AMBROSE H. DOUGLAS died of pneumonia at the Leona mine, Matagorda, Nicaragua, on May 1. Mr. Douglas was well known at Silver Peak, Rawhide, and other Nevada camps as a man of ability and of extraordinary regard for rectitude and honor.

General Mining News.

ALASKA.

A. L. Slow and 85 men have sailed from Seattle to open the Alaska Central railroad from Seward to Placer valley. The road, of which 55 miles are completed, has been out of commission, and in the hands of a receiver since November 1907. The finished portion of the road will be put in running order at once, and 20 miles of new road across Placer valley into Turnagain will be constructed. Five hundred men will be employed.—The Copper River & Northwestern railroad has completed its steel bridge across the Copper river at Flag point with a span 560 ft. long. The road will be open through Abercrombie canyon some time this month.—The Mt. Andrews Copper & Iron Mining Co., operating the Mt. Andrews mine situated on Prince of Wales island, in Ketchikan district, recently made a shipment of 2400 tons of ore to the smelter at Tacoma. This is a copper ore, running high in iron, being desirable as a flux to mix with the silicious ores from western Washington. The Mt. Andrews was formerly operated under lease by the Britannia Smelting & Refining Co. Sam Lichtenstadter is now manager of the property.

ARIZONA.

GRAHAM COUNTY.

Nathan L. Amster, president of the Shannon Copper Co., has been in Clifton conferring with J. W. Bennie about the construction of their designed railroad to be called the Shannon & Arizona. It will be 10 miles in length to connect the mine with the mill, and will be of standard gauge. The surveys have been made for this new road, which in addition to the saving in freight charges will give immunity from annual floods that now cause heavy damages. It is estimated to cost \$400,000 and will save about \$80,000 per annum.

MARICOPA COUNTY.

The Vulture Mines Co. took possession of the Vulture gold mines in Arizona in September 1908, and also took over the 80-stamp mill and 100-ton cyanide plant. In the mine development work required only unwatering and repairing of tracks. The first month was spent cleaning up. Since October 1 new development has been carried on with the utmost vigor, and more than 50 men are now at work. Large orebodies have been encountered on the 450-ft. level, and are being blocked out.

PIMA COUNTY.

The first report made by the Oxide Copper Co., operating near Silverbell, shows that 263,400 tons of ore were extracted, carrying 49,600 lb. copper, with a little silver. Frank Higgins is superintendent.—A. N. Jack, manager for the Arivaca Mine & Milling Co., states that work has been resumed at the mines and that living houses, blacksmith shops, and other necessary buildings are being erected. An adit is being driven, and has been advanced 150 ft. A drift on another part of the vein shows ore averaging \$10 in gold and silver.

CALIFORNIA.

INYO COUNTY.

(Special Correspondence).—The April output of the Keane Wonder mill was approximately \$28,000. The 100-ton cyanide plant has been in commission since March 15, and has nearly doubled the production. The new shaft is down 100 ft. and will be sunk to the 200-ft. level before any lateral work is commenced. At the present time the shaft is in the best ore yet found in the mine. A 25-hp. hoist will be installed on this shaft at once.—A 30-ft. vein, assaying in places \$11 per ton, has been cut at a depth of 12 ft. in the Pennsylvania group, owned by the Barton Bros. The property is situated six miles southeast of the Keane Wonder.—Ten stamps are dropping at the Skidoo mill on ore running from \$20 to \$25 per ton. From 35 to 40 tons are being handled daily. The company is refusing to renew leases. It is expected to have 15 stamps in action

before the end of May.—A large reserve of milling ore has been developed at the Cashier and a 5-stamp mill is being erected.—The Valley View, American Eagle, Contact, and several near-by properties are producing on a small scale.—Steady developments are under way at the Black Canyon, Red Rose, Southern Belle, and other local properties, but nothing of an important nature has recently developed.—The Tecopa Co. is considering the installation of a 4-furnace silver-lead smelter, with a capacity of 600 tons per day. The plant will be erected at Tecopa and a 15-mile railway line will be constructed from this point to the Gunsight and Noonday mines. It is understood that everything has been settled save the signing of the contracts by the president of the Tecopa Co. The company recently negotiated for the Needles smelter, but the deal fell through, owing, it is reported, to the refusal of the railroads to grant desired rates.

Bishop, May 1.

NEVADA COUNTY.

(Special Correspondence).—Ore milling from \$30 to \$50 per ton is being taken from a 14-in. vein at the Ben Franklin. The ore is treated at the Larkin mill.—The shaft at the Nichols mine is being unwatered and active work will soon commence.—The shaft at the Hill mine, in the heart of the residence district of Grass Valley, has been unwatered and driving on the vein is under way. The mine is under lease to a company of local miners.—Operations have been suspended at the Norambagua because of the bursting of the water-wheel. An order has been placed for a new wheel.—Forty stamps are dropping at the Idaho-Maryland mill. The 8-ft. vein of high-grade milling ore developed in the 500-ft. level has been intersected at the 600 and 700-ft. points, and shows equally good stuff. Several men have been added to the working force.—Work is being pushed on the Greek vein at the Union Hill mine. The working crew is being steadily increased. Clifford Graham is superintendent.—Thirty-six men are working at the Delhi and considerable development work is going on. Repairs to the mill have been completed and 20 stamps are in action. Hamilton Eddie is superintendent.—Operations have been resumed at the Greystone mine and a new adit has been started, which will tap the vein about 800 ft. from the portal. This will give backs of about 600 ft. George Hegarty is superintendent.—The Lecompton has been unwatered to below the 300-ft. level and it is expected to start the mill within 10 days.—Arrangements have been perfected for the extensive operation of the Cold Springs property. The adit will be pushed ahead in the hopes of striking the main channel. The channel now opened will be systematically worked. Harry B. Adsit has been appointed manager.—The Oustomah has been re-opened and the 10-stamp mill is crushing \$20 ore from a 2-ft. vein between the 300 and 500 ft. levels. The shaft is being sunk steadily and has nearly reached the 1000-ft. level. At this point the vein is 2 ft. wide with 2 ft. more of mineralized matter carrying numerous small stringers of quartz. Frank M. Evans is superintendent. The mine is under bond to E. H. Wilson of Alleghany.

Grass Valley, May 3.

TUOLUMNE COUNTY.

The New Aurum Mining Co. is making good progress in the extensive work being done at its group of mines on Hunter creek southeast of Tuolumne. The track from the War Eagle to the mill has been completed and milling has begun. Ore is being extracted from the Hunter and War Eagle, and a big supply of it assures a long and steady run. It is intended to unwater the Hunter, which is 400 ft. deep, and carry on work in the several drifts. The War Eagle adit has reached a length of 200 ft.—A. Davidson, of Fresno county, and associates have resumed work at the Fay and Jewel mines, situated southeast of Tuolumne.—A 5-stamp mill is being erected at the Eureka mine, near Big Oak Flat.—Operations have been resumed at the group of mines near Tuolumne formerly worked by the United Mines Corporation. The property is under lease to the Erie Mining Co. The cyanide plant has been moved from the Dead

Horse claim to a site near the new mill, and other changes have also been made. The crew of men employed is being gradually increased and within a short time all parts of the property will be in operation.—One hundred tons of ore from the Santa Ysabel mine, which is being operated under lease by McGinn Bros., yielded \$20 gold per ton. More ore is being taken out, and on a more extensive scale.—Three veins ranging from 20 to 25 ft. in width and of good milling ore have been uncovered at a depth of about 200 ft. in the Gold Crater mine at Knight's creek. During the last four years the company has spent more than \$100,000 on the property and done 2000 ft. of development work.

YUBA COUNTY.

The American Mining & Development Co., operating at Snowden Hill, 9 miles above Camptonville, is driving a bed-rock adit to develop an old river channel. It is planned to run about 1½ miles of underground work. R. G. Mead, assistant general manager of the company, has recently been in San Francisco, where he purchased a two-drill compressor and two 2¼-in. drills from the Sullivan Machine Co. The compressor is to be belted to a water-wheel made by the Joshua Hendry Iron Works. A small electric light plant was also purchased.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Sigafos boring machine, which has been installed at the Georgetown adit on Columbia Mtn., was tried out for the first time with water this week. In four minutes 2 in. of ground were broken. The machine then broke down as in former demonstrations, owing to the fracture of a shaft. The test was witnessed by the graduating class of the State School of Mines at Golden.—The 50-ton mill of the Terrible mine is now running steadily on ore from the lease operated by Wood & Co. on the fourteenth level. About 50 tons of lead-zinc ore from the Smuggler mine are also being handled each week. Shipments of smelting ore from the Terrible are being sent to the Georgetown sampler, and fetch returns averaging \$90 to \$100 per ton in silver and lead.—The shaft of the Smuggler mine is 375 ft. deep, and is being sunk a farther 150 ft., with levels at 75-ft. intervals. Machine drills are being brought into play to increase the speed of sinking.—The 25-ton mill of the Honest John Mining, Milling & Tunneling Co., up Chicago creek, is now running night and day on ore from the Black Eagle mine. The compressor recently installed at the collar of the shaft was pulled out last week and a larger one is being placed in position. It has been decided to sink the shaft another 150 ft., as the ore-shoots appear to continue downward. J. F. Puchert is manager.

Georgetown, April 30.

TELLER COUNTY.

A rich ore-shoot has been opened on the ninth level of the Modoc mine, between Bull hill and Battle Mtn. It does not exceed a foot in width, although most of the vein is 4 ft. between walls, yet is far more valuable than the full-sized vein. A 30-ton shipment has been sent out by the general manager, F. H. Frankenberg, to the smelter at Pueblo. The Modoc mine is operated both on company account and under the leasing system, but the new strike was made by miners in the employ of the company.—The permanent water-level in the Portland mine is less than 40 ft. above the 1500-ft. level. All of the orebodies on the 1500-ft. level will have been stoped out during this month. After that, all pumping will be stopped and the remaining ore taken out through raises to the level above. This will save the pumping expense that has averaged from \$3000 to \$3500 per month during the last year.—An electric tramway is being installed by the Cresson Consolidated Mining Co., to transport ore and waste from the shaft to the ore house or dump.

IDAHO.

BONNER COUNTY.

There is much excitement in and near Clark Fork over a find of gold-bearing ore by Leroy H. Whitcomb, a merchant of that town, on Antelope Mtn. and many have staked out

claims adjoining the ground on which the vein appears. Samples of ore show excellent gold assays.

IDAHO COUNTY.

Walter B. Pittock and James Coverly, one time owners of the Buster mine near Elk City, have brought out specimens of ore from the Snowstorm property which ranks with any yet seen from the district. The property is owned by the Pittock brothers and Coverly. They have one adit 210 ft. long on the 105-ft. level, running in ore which extends to the surface. They also have struck the vein in another adit on the 175-ft. level, from which the rich specimens were obtained. Six ounces of pulp panned out more than \$6 in gold. There are from 4 to 8 in. of this material running through the centre of a vein from 3 to 5 ft. wide that is also quite rich.—Frank J. Marvin, of Spokane, and William F. Newton, of Goldfield, have bonded the June Bug group of 5 claims, near Elk City, for \$30,000. Newton will remain on the property arranging the camp, and men will be put to work on development at once. A great amount of open cross-cutting has been done and the pay-shoot has been opened for more than 400 ft. Assays from \$36 to \$300 per ton have been obtained.—J. H. Shearer, of Buffalo, and his associates have bonded the Redfern placer ground, along the Salmon river, from G. H. Vessey for 60 days for \$35,000. The property is known to be rich and comprises 270 acres, but, like the Moscow bar, at the headwaters of the North Fork of the Clearwater, it is placed high, and getting water to the gravel will be expensive. A long ditch is to be dug, and a gasoline pump will be installed the coming summer.

LEMHI COUNTY.

It is hoped that early in June the new smelter being installed by the Lemhi Smelting Co. at Nicholia will be blown-in on ore from the company's Lemhi Union mine. The smelter will have a capacity of 100 tons per day. Besides the Lemhi Union, the company owns another mine in the same vicinity, known as the Teddy & Elizabeth, where 20 men are now employed. D. E. Coughanour is manager for the company, and C. M. Stoley is superintendent.—There is a great deal of activity in the county, as the Oregon Short Line has crews working at both ends of its proposed line from Armstead, Montana, to Gilmore, in the southern part of the county. The rails will be laid this summer and a rich mining and agricultural country will be opened up.

OWYHEE COUNTY.

(Special Correspondence).—The Pauper mine on War Eagle Mtn., operated by R. H. Leonard, is producing some good ore, and in sufficient quantity to start up its mill which was recently built. From the Burro mine, in the same place, Inglis & Nettie are taking out ore which shows free gold, and sending it to their mill just above Silver City.—The Silver City Mining Co. is waiting for the snow to melt before installing electric power for running its compressor. A cross-cut adit is being run 2200 ft. long to cut a vein. The machinery arrived too late last fall to permit being set up at that time.—The Banner Mining & Milling Co. is still driving its mill level or Erdman cross-cut to reach the main vein at a depth of about 700 ft. There have now been driven 1060 ft., and 300 ft. still remain to be done. Waugh drills have been used, and have made the fastest time in the district. During advance several veins have been intersected, one of which has 6 ft. of good milling ore and a narrow streak on the foot-wall of high-grade material. As soon as the main vein is reached development will be started on all the veins. A mill has already been built containing Nissen stamps, Johnston vanners, and Wilfleys, followed by Callow tanks and pan amalgamation. Peter Steele is general manager, and J. F. Inglis is superintendent.

Silver City, May 1.

SHOSHONE COUNTY.

The Northern Light Mining Co. of Wallace will develop a property on Pine creek which has already been extensively developed. In the bottom of a 16-ft. shaft from 12 to 15 in. of solid galena ore has been exposed, and two short drifts were driven, which have also made a good showing. Machinery will be installed and extensive development will be started at once.

KANSAS.

CHEROKEE COUNTY.

(Special Correspondence).—Preparations are being made for increased production in the Galena camp. The Clermont Co. south of the city is planning the early erection of a large mill to treat the ores opened up last year. This company owns in fee 294 acres and holds under lease more than 200 acres more. Thorough testing of the ground was made last year, resulting in the discovery of large ore deposits both at shallow and deep levels. One run of ore was found at 160 ft., while a better one showed at 250 ft. A shaft is down 170 ft. and has penetrated the first run.—What is proving to be one of the most extensive mines in the Kansas field is being developed by A. O. Ihlseng on the Robertson and Ping tracts. A large new 400-ton mill is to be built, half on one lease and half on the other. The dirt from each lease will be treated separately in the mill. The ground has been extensively tested and found to be mineralized to the 300-ft. level. This will be one of the deepest mines in the district.

MICHIGAN.

F. G. Coggin has resigned the superintendency of the Atlantic stamp-mill at Redridge and will be succeeded by W. E. Carpenter, at present master mechanic of both the

Shipping Ingots From Copper Range.

Baltic and Atlantic mills. Edward Koepel, superintendent of the Trimountain mill, will also take charge of the Baltic and Champion mills, all three belonging to the Copper Range Consolidated Co.—Though occasional patches of poor ground are encountered, the lower levels in the Trimountain mine continue in fairly well mineralized ground, the general average of which is undeniably a big improvement over that opened during the past years. The company has 53 machine drills at work, and is sending about 1000 tons of 'rock' to the mills daily.—The Beaver dam, near No. 5 shaft of the Tamarack mine, which had been rising rapidly for two weeks, broke through its banks recently and sent a flood of muddy water into the shaft. It was found necessary to suspend operations at the mine till the flood subsided. But little damage was done, and the shut-down was quite short.—Connections have been effected between the No. 1 and 2 shafts of the Hancock mine. Henceforth nearly all the ore developed near No. 1 will be hoisted through No. 2, which is a 5-compartment vertical shaft, and one of the largest in the Lake Superior district. At present it is 1800 ft. deep, and should cut the main Hancock lode with about 400 ft. farther sinking.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—An era of mill building has begun in the Missouri-Kansas district. In the Prosperity and Duenweg camps several mills have just been completed. The Highland mill of 400 tons has been built to replace the one destroyed by fire last fall. East of this the Lincoln

Mining Co. has finished a new plant and has installed Richards pulsator jigs, which are a new feature in this field. On an adjoining lease the Wolfsheart Co. is erecting a mill on a lease which was well tested and developed last year. There are a number of other companies which have rebuilt their plants and moved mills from other parts of the district.—Following the unexpected strike of zinc ore in the bed of Spring river east of Carthage some weeks ago, the mining fever has taken possession of many of the land owners in the vicinity, and hundreds of acres have been leased for mining purposes. A good strike has just been made on Dr. L. C. Carter's land, where the drill entered ore at 90 ft. and continued to 205 ft. Another hole has been started.—The Continental mine in the Porto-Rico camp has resumed operations after a two months' shut-down during which repairs were made. This mine has put mules in the drifts to haul the cars of ore from the face to the shaft in order to increase the capacity of the mine.—A new tailing mill is being built on the lease of the Prairie

The Missouri-Kansas Zinc Belt.

Chicken Mining Co., near the site where the old mine has been in constant operation for many years. Vast tailing piles have accumulated, and these have from time to time been removed for ballast for the railroads, but never before treated in a mill. There is still a large pile ready to be treated which contains a good percentage of zinc.—A new 150-ton mill has just been completed on the Degraff brothers lease west of Joplin. The mill was the former Alice of Old Vincennes in the Chitwood camp, but has been re-built and new machinery added. The ore here is of the disseminated type and special machinery has been installed for its treatment. The mine has been developed to the 180-ft. level, where a face of ore 20 ft. high is being worked which runs from 10 to 12% zinc. Two shafts are down and a tramway carries the ore from the north shaft to the mill.—The Little Jew mine southwest of Joplin has been revived and is again in the producing list. It was closed down during the low ore prices. A new company has undertaken its development and has sunk a new shaft.

Joplin, May 1.

MONTANA.

JEFFERSON COUNTY.

Arrangements have been made to resume operations in the property of the Brooklyn Bridge Mining & Milling Co., at the head of Lump gulch, about six miles from Clancey. The company owns 15 claims, of which three are patented; a 150-hp. boiler and Lidgerwood hoist good for 1000 ft., and a Davis calix drill. Two thousand feet of development work, half of which is in shafts, have been completed, the

deepest shaft being 435 ft. The rest of the work is in drifts.

MISSOULA COUNTY.

F. D. Willard, secretary of the Saltese Consolidated Mining Co., operating a group of claims near Saltese, has announced that a 20-ton reduction plant will be installed in June. J. E. Mason Bennett, formerly of Pueblo, Colorado, will have charge of the plant. The main adit has encountered a blind vein 3 ft. wide and assaying 14% copper across the entire width. The miners then drifted 90 ft. on the vein and the ore was found to improve. The adit has been run 350 ft. beyond the blind vein, and it is hoped to reach the main vein in less than 100 feet.

SILVER BOW COUNTY.

Counsel for the Deer Lodge farmers have submitted an offer to arbitrate with a view to securing damages from the Anaconda and Washoe companies, or in lieu of that to dispose of their lands to them. The proposition of the farmers is to arbitrate the question of damages, and if the awards are not satisfactory to the company they will submit their lands for condemnation under the law providing for the condemnation of lands for public use.—The Corbin Copper Co. has cut a new vein in the Dewey adit, assaying 5% copper. Five other adits are being driven for veins. F. Richards says the property is in condition to ship ore if the company so wished.

NEVADA.

ESMERALDA COUNTY.

E. Hampton has resigned as mine superintendent of the Goldfield Consolidated Mines Co., and his place will be taken by H. P. Henderson of the company's staff. Henderson is a graduate of Harvard, and for some time was superintendent of the Belmont mine at Tonopah.—An official report has been issued by the Goldfield Consolidated, stating that for the first quarter of the present year the earnings of the company were \$1,905,245, the expenses \$306,480, and the net profits \$1,598,764. The ore output for the quarter was 46,119 tons, of which 45,747 tons were milled and 352 tons shipped. The average costs per ton were \$3.70 for mining, \$2.53 for milling at both mills, and \$0.16 for transportation, making a total average cost of \$6.346 per ton. The cost of operation has steadily decreased. After paying dividend No. 3, on April 30, 1909, the company had on hand in cash and liquid assets more than one million dollars.—E. Stuart, State Mining Inspector of Nevada, has appointed Ed. Ryan of Goldfield as his deputy.—The *Goldfield News* states that the Lucky Boy and Mountain King group, at Lucky Boy, has been optioned by J. H. Miller to a representative of the U. S. S. & R. Co. for a million and a half.

NYE COUNTY.

Thomas G. Lockhart, president of the Goldfield Florence Mines Co., has purchased a group of placer claims from J. W. Riggle for \$10,000. The claims are considered among the richest in the Manhattan dry placer section, and lie between the Big Six and Happy Hooligan claims. A lease on one of the claims secured by Mr. Lockhart has been panning ground running \$40 per cu. yd. Other Goldfield people are acquiring placer locations in Manhattan and are arranging for extensive operations.—In the Tonopah Mining Co.'s property the stopes on the Mizpah, Valley View, and Silver Top veins continue to yield the regular tonnage. Sinking continues in the Mizpah and Red Plume shafts, and the latter is within 28 ft. of the desired depth before lateral work is taken up and prospecting begun. The bottom of the shaft shows a broken formation of no economic value. The mill report for the week shows that an average of 93 of the 100 stamps were dropping constantly, crushing 3020 tons of ore, with an average value of \$21.50 per ton. Between 35 and 40 men are engaged in completing the mill of the Jefferson Gold Mining Co. at Round Mountain. James McDonald, the superintendent, has the building finished, and it only remains to fix the rest of the machinery.

STORY COUNTY.

The weekly report from the Comstock mines and Summit

tunnel shows that a considerable amount of re-timbering and repairing has been carried out. At the Ward shaft sinking is being continued, and the total depth reached is 2549 ft. Two sinking pumps have been lowered into position. In the Ophir work is being done on the 2000, 2100, 2200, and 2300-ft. levels, and shipments have been made of 312 tons to the Kinkead mill and 54 tons to the Butters plant.—No work was done in the Gould & Curry, Savage, Hale & Norcross, Chollar, and Potosi mines during the week. The Yellow Jacket mine extracted 210 tons from the 1200-ft. level, and milled altogether 933 tons, most of it coming from the dump.

WHITE PINE COUNTY.

The contract for carpenter work and machinery erection in the fourth unit of the Steptoe concentrator has been awarded to the Hughes Construction Co. of Denver. The time allowed for completion is 90 days, after which the machinery must be put through a satisfactory run of seven days before the unit will be accepted by the company. Experience having demonstrated that the Steptoe concentrator is somewhat deficient in Wilfley table capacity, the management has conceived the idea of double-decking the Wilfley floor and thereby gaining room for nearly twice the number of tables at first employed. The second deck of Wilfleys is now in operation in two of the three units of the mill, and the results are said to be highly satisfactory.

OREGON.

BAKER COUNTY.

The Cougar mine at Granite has been idle for the last six years. In consequence of the examination by Theodore L. Lammers, of Spokane, on behalf of the National Mining & Leasing Co., the mine is to be reopened and operated on lease till June 1910. Some 2000 ft. of development work has been completed in the underground workings, and ore-shoots over 200 ft. in length have been opened, the vein in places being from 15 to 17 ft. wide. Equipment on the surface includes a crushing and cyanide plant, which are now undergoing alterations and repairs.

LINCOLN COUNTY.

Plans for a mill and a third adit 200 ft. below No. 2 adit are being made by the Gold Success Mining Co., which owns 12 claims near Elk City. Charles E. Skiles, of Denver, is president of the company, and D. S. Cowgill, of Spokane, secretary and treasurer. J. Y. Smith, the manager, announces that more than \$25,000 worth of ore is already blocked out, and that it is expected to install a 10-stamp mill before next fall. One hundred and forty feet have been run on No. 2 adit since September 1908, making a total length of 440 ft. from the portal.

UTAH.

BEAVER COUNTY.

The Horn Silver Mining Co., in the San Francisco district, has issued its annual report for 1908. It shows that during the year the company did 1477 ft. of deadwork consisting of raises, drifts, and winzes. On the 500-ft. level and extending down to the 600-ft. level considerable silver-lead ore has been developed that should produce a fair tonnage. The zinc ores remain practically undisturbed. On account of the low price of spelter a market could not be found for this class of ore. Prospecting is now going on on the 100, 500, 600, and 700-ft. levels in a new territory. The profits of the company for the year were \$3333. The average value of ore shipped was \$9.44 per ton. M. C. Morris is general manager.

SALT LAKE COUNTY.

A large force of men is installing machinery in the Ohio Copper Co. reduction plant at the mouth of the Mascotte tunnel. Not all of the equipment has been delivered and Colin MacIntosh, the general manager, says that it will require from three to four months' time to have the first section completed. This first section will have a capacity of 2250 tons of ore per day.—A large force of men has arrived at the Highland Boy smelter to commence the work of tearing down the structure. All the steel will be shipped

to Tooele, where the International smelter is now under way. The Highland Boy smelter employed over 1000 men, and treated about 800 tons per day, producing 99% blister copper. Owing to trouble with the agricultural interests in the Salt Lake valley a court decree enjoined the company from smelting ores carrying more than 10% sulphur, and from sending out arsenical fumes. The farmers at first demanded \$300,000 for permission to allow the smelter to run, which was refused, and in January 1908 the plant was closed down.

TOOELE COUNTY.

The Western Utah Copper Co.'s mine in the Deep Creek district is to be developed on a comprehensive scale by Duncan McVichie. The mine is about 100 miles from a railroad, and was closed down late in 1907. On the 80-ft. level is an orebody 85 ft. wide, which is of the same width on the 150-ft. level. The company claims to have over 100,000 tons of 5% copper ore blocked out.

CINTA COUNTY.

George H. Mulvey, superintendent of the Pittsburg & Salt Lake Oil Co., will operate the gilsonite mines of that company at Vernal in a different manner to that previously adopted. The hydro-carbons give off a dust that is highly flammable, and caused a bad explosion in February 1908 when blasting in the Dragon mine. It has now been found that blasting can be superseded by the use of steam-points, which effectually cut out the material without any danger.

WASHINGTON.

FERRY COUNTY.

The Lone Pine ground of the Pearl Consolidated group, from the lower adit level to the surface, has been leased to a former superintendent and a stockholder, representing the majority interests, for one year. The lessees of the Surprise ground, belonging to the same group, are shipping a carload, and sometimes two, of ore per week.

A fine body of ore has been found on the 300-ft. level of the Lucille Dreyfus mine. The property is now in good shape for breaking ore, and a contract has been let for a 500-ton shipment to the Spokane & British Columbia railway, for transit to the Granby smelter.

LEWIS COUNTY.

The Mayfield district, situated 20 miles southeast of Chehalis, is attracting considerable interest. Over 100 men are now on the ground prospecting and exploring, and about 20 outfits are engaged in sinking shafts, driving adits, and making open-cuts. The most conspicuous of these is the Consolidated Gold & Copper Co. of Seattle, at the head of which is W. H. Springfield. The district covers an area of about 15 square miles in the well-settled farming section of Cowlitz valley. The ore consists of basalt, carrying free gold, assays of which run from \$2 to \$60 per ton. Ore of this character outcrops and is said to be richer as depth is gained, the deepest workings not being more than 60 ft. All the ground being prospected is owned by farmers whose titles do not give them the mineral rights. This tract of country was granted by the Government to a railroad company some years ago, the mineral rights having been reserved by the Government. The present owners obtained their titles from the railroad company, which could grant only surface rights. The farmers are said to be co-operating with the miners in having the country prospected.

OKANOGAN COUNTY.

The Molson Gold Mining Co., in Myers Creek district, has installed in its mill six Nissen gravity stamps and plates with self-feeders for handling the ore. Each stamp weighs 1300 lb. and has a drop of 7 in. The mortar blocks stand on massive concrete foundations. In addition the mill is equipped with two latest pattern Willey concentrating tables.—The Oroville Consolidated Mining Co. has a vein on the Blue Bell claim, which adjoins the Gold Dust property, 50 ft. wide at the surface and carrying copper. Ore taken from an open-cut on the same vein shows free gold. This vein is being well explored.

STEVENS COUNTY.

(Special Correspondence).—In Chewelah district the Chewelah Copper Mining & Smelting Co. is about to establish

a reduction plant, to be built in two units of 50 tons capacity, at an estimated cost of \$25,000. The company will purchase custom ores.—In the Metaline district, the Oriole company has a car of ore sacked awaiting shipment. A shaft will be sunk on the vein and continued to a depth of 450 ft. The ore as broken will be shipped probably to the Panhandle smelter at Sandpoint, Idaho. A hoist and blower have been purchased and will be installed at the shaft.—The main vein on the Blue Jim mine assays about \$60 in gold, silver, and copper and ranges from 4 to 10 ft. in width. In the cross-cut adit, at a depth of 80 ft., a 4-ft. vein has been cut, but the value has not been given out.—The No. 6 furnace of the Northport smelter has been run recently on First Thought and Le Roi ore, flue dust and bricks from the roast beds, to make a general clean-up.—Henry Garrett, owner of the Longstreet mine, on the Columbia river in the Enterprise mining district, near Hunters, reports that he has struck a vein at a depth of 90 ft. which assays \$62 in gold and silver. The ore contains also an average of 8% antimony.

CANADA.

ONTARIO.

There were seven mills in operation around Cobalt during the past year. They are the Buffalo, Cobalt Central, Conia gas, King Edward, McKinley-Darragh, Northern Customs Concentrator, and the Nipissing Reduction Co. Concentration is carried out in the ratio of 40 or 45 to 1 for the product of all the big mines. Four companies have mills under construction. The price for cobalt gradually went down in 1908 till at the end of the year it was almost unmarketable. The Anglo-French Nickel Co., of Swansea, Wales, paid 36c. per pound for 8 to 10% cobalt, and 55c. for ore running 16% or more. After April the prices went down again and now the Canadian Copper Co. and the Deloro Mining Reduction Co. offer practically the only market for cobalt, and they will only accept it when it runs 6% and the nickel contents are lower than the cobalt contents. No smelters now pay for arsenic or nickel.

MEXICO.

JALISCO.

E. R. Haggin, of Los Angeles, has become representative for an Anglo-French syndicate which intends operating the Mina Grande in the Hostotipaquillo district. Last year a deal for a controlling interest in the Mina Grande was made with the Dwight Furness Co., of Guanajuato, which owned the property, by Luis Chevrillon, of Mexico City. The Mina Grande is an *antigua* with a long record of former production.—The San Rafael mine in the Parnaso camp, is now being worked under an option from H. H. Sawyer, of Guadalajara, by J. B. Murray and George H. Watt, who have interested Scottish capital. Sawyer was formerly connected with the San Rafael mine, while Watt came from Guanajuato.

MEXICO.

The El Oro Mining & Railway Co. reports for March: Mill No. 1 ran 31 days, mill No. 2 ran 30 days, crushed 26,631 tons of ore, yielding bullion \$214,740; working expenses, \$118,490; expenditure on development, \$23,121; total, \$141,611; profit, \$73,129; profit on railway, \$4000; total profit, \$77,129; expenditure on permanent improvements, \$1000.

OAXACA.

G. N. Grigsby and E. L. Spurck have taken up 22,000 acres of land for the Mexican Agricultural Land Co., on much of which are placer deposits which they consider valuable. The property of the company is 45 miles southwest of Tierra Blanca, on the Veracruz & Pacific railway.

SONORA.

The Lucky Tiger mine is under option to a New York and London syndicate until July 21 for a sum said to be \$7,000,000. Thomas H. Leggett and Frederick Hellmann are now engaged in examining the property. C. W. Mitchell, engineer for the company, says that the company completed 10,000 ft. of development in 1908, and is doing 1000 ft. a month in drifts, cross-cuts, raises, and winzes. There are about 350 men employed in the mine and mill.

Special Correspondence.

MEXICO.

Enlarging Chihuahua Smelter.—Encinillas Smelting Co. — Conchos River Placers.—Palmilla Tunnel Completed.—Pedro Alvarado.

Enrique C. Creel, governor of Chihuahua, is doing everything in his power to induce the American Smelting & Refining Co. to increase the capacity of its smelting plant at Morse. It is a strong point with the governor to make Chihuahua an important mining and smelting centre, and he expresses the hope of eventually seeing 15 furnaces in blast at the Chihuahua plant. Such a number is, of course, quite out of the question, being in excess of any A. S. & R. Co.'s plant, even in more important mining centres than Chihuahua may ever expect to become. Many single camps in the United States produce a greater tonnage than the entire State of Chihuahua. But it is known that plans have been drawn for increasing the present 3-furnace Chihuahua plant to 5 or 6 furnaces, and the same are now under consideration at the New York offices of the company. As such changes would mean material additions to the power-plant, buildings, and track-system, it would be close to the end of the present year before they could be completed, even if decided upon. The company is putting in aerial tramways to its Santa Eulalia mines. The one to Mina Vieja is completed, and it is understood that a branch will be run to the Santo Domingo mine also, in order to sufficiently increase the output from these properties to supply the needs of the El Paso smelting works as well as those of the Chihuahua plant for these desirable silver-lead ores. It is understood that the little Santa Rosalia plant of the Encinillas Smelting Co., Ltd., has been shut down for some time after a rather short and not very successful run, but it cannot be learned whether the closure is to be of long or short duration, nor whether the trouble is due to lack of ore, metallurgical problems, shortage of water (which has been worrying the company for some time), or to financial difficulties. The mining interests throughout Chihuahua continue slowly to improve. The Republica Mining Co., in western Chihuahua, has its mine and mill in such condition as to enable it from now on to pay a 1% per month dividend. Joseph S. and Charles Qualey, whose excellent property in the Yoquiva district has been recently mentioned in these letters, are preparing to prospect with a churn-drill the placer grounds of the Dale Bros., of Chihuahua, and John R. Roslyn, of New York. These adjoin the Santo Domingo placers on the Conchos river in eastern Chihuahua, and, if the ground proves as claimed, dredges will be erected for working the placers on a large scale. The Qualeys have also put things in shape for a resumption of operations on their Parcionera mine in Santa Eulalia.

In the Parral district the Palmilla tunnel has been completed on that property, being 343 metres long by 3 high and 2½ wide. It will make a saving of 133 m. in the lift of the water from the mine. That should soon pay the cost of the tunnel, and it is expected that a spur may be run over from the Parral & Durango railroad to the mouth of the tunnel, and thus do away with the aerial tram. The Palmilla is under a 15-year lease to Boston people, and it is understood that the owner, the once famed Pedro Alvarado, has sold this property, which has yielded him several millions, for \$200,000. That amount will scarcely pay his debts, so that he bids fair to become soon again a simple ordinary miner, or a mine-boss, working for day pay. At the Tecolotes mill (in Santa Barbara), of the American Smelters Securities Co., 800 tons per day are being treated, and by a combined, direct re-crushing, classification, and fine concentration, excellent results are being obtained, and the mill is working up to practically full time, at least over 98%. For the 35,000 to 40,000 tons of zinc middling that has been produced it is stated that appropriation has been made by the company for the installation of a zinc separator.

The famous old copper mine, La Mina Cobriz, now called El Tesoro, situated nearly 30 miles from Mazatlán, at Villa

Union, is under option to English capitalists for a large sum. The mass of copper ore exposed is 5000 ft. long, and from 400 to 1200 ft. wide. It is said to average 4% copper and to contain 0.5 dwt. gold and 4 oz. silver per ton. In the early days great quantities of *magistral*, roasted copper-iron sulphide, were here produced for use in the patio process.

H. S. Denny, of the firm of Denny Brothers, mining engineers and metallurgists, of Mexico City, London, and South Africa, is a firm believer in the possibilities of Mexico as a mining country. In speaking of the mining industry in the Republic of Mexico and its future possibilities, Mr. Denny said through the *Mexican Herald*: "The average mine in this country is really no more than a prospect possessing practically no development, and it would appear that the general policy has been to pay attention to and to ship only high-grade ore. This work has been carried on, in a majority of cases, regardless of the principles of scientific mining development and in most cases such work is to the detriment of the mine and the owner."

"In considering the possibilities of the mining industry in the Republic of Mexico, I can say only that I am surprised with the results thus far obtained. Whether we judge the country from the standpoint of area of mineral distribution or from the variety of minerals to be found, or from the richness of the ore deposits, or from the natural working facilities, Mexico can claim equality with any mining country of the world, and for a combination of all these factors there is surely no other that can approach it. When compared with South Africa and Australia, I find that the great lack here is capital to carry out the enterprises offered."

In many respects the greatest event in the history of Mazatlán and the State of Sinaloa was the completion of the Southern Pacific railway to that point on April 18. Governor Cañedo arrived from Culiacán in a special train of four coaches. On the train were the superintendent, Ingram, the chief engineer, and a large number of distinguished persons from Culiacán and Guaymas. At the conclusion of a banquet the committee escorted the governor to the spot where the last rail-joint waited the driving of the golden spike.

SLOCAN, BRITISH COLUMBIA.

Standard. — Vancouver. — Richmond-Eureka. — Ruth. — Rambler-Cariboo. — Lucky Jim — Whitewater.

Among the mines of Slocan district the most prominent at present are the Standard and the Vancouver, of the Van-Roi group, in Silverton camp; the Richmond-Eureka, Hidden Treasure (the latter of the Slocan Star group), and Ruth, near Sandon; the Rambler-Cariboo Co. mine in McGuigan basin; the Lucky Jim, near Bear lake; and the Whitewater group, in Whitewater camp, which, as well as the Lucky Jim, is in the eastern part of the Slocan district. The Standard and the adjoining Emily Edith, on Four-Mile creek, Slocan lake, are being worked conjointly by G. H. Aylard, of New Denver, B. C., and John A. Finch, of Spokane, Washington. The former is in charge of operations. The Emily Edith group of mineral claims was formerly owned by the Emily Edith Mines, Ltd., of London. It has been opened by six adits, which, together with other underground work, have a total footage of about 9000 ft. The aggregate tonnage of ore shipped is not yet large, but a considerable quantity of concentrating ore is available. The Standard had been opened by four or five adits, and the mine has been energetically worked during the last two or three years. Its output last year consisted of about 1250 tons of first-class ore shipped to the smelter, and a similar quantity of milling ore placed on the dumps. The metal contents of the first-class ore were 106,000 oz. silver and more than 1,600,000 lb. of lead. The milling ore will, it is estimated, concentrate 4 to 1 and contain much zinc. The Vancouver group, a lease and option to purchase which were last summer transferred to the Van-Roi Mining Co., Ltd. (an offshoot of the Le Roi No. 2, Ltd.), of London, is

being actively developed under the direction of Paul S. Couldrey, manager of the Le Roi No. 2 mines at Rossland, B. C. Last year's shipments consisted of about 500 tons of lead concentrate and picked ore, containing 72,000 oz. silver and 594,000 lb. of lead, and 1038 tons of zinc concentrate averaging 45% zinc and 42 oz. silver per ton. The first half of a 12 by 18 D 2 Rand air-compressor, which at that elevation will run about three large piston-drills, has been installed. It is driven by water-power, a flume and pipe-line 4000 ft. in length conveying the necessary water. It is intended to erect a concentrating mill near the mine, and for this a site has been graded and cribbed. The Richmond-Eureka group is owned by the Consolidated Mining & Smelting Co. of Canada, Ltd., with head office in British Columbia at Trail. W. H. Aldrich is managing director of the company, and A. W. Davis, of Sandon, local superintendent of the Richmond-Eureka mine. The vein opened on one claim of this group passed through a part of the Hidden Treasure claim of the Byron N. White Co.'s Slocan Star group, and thence into another claim of the Richmond-Eureka group. About 2900 tons of silver-lead ore of good grade were shipped last year from the Richmond-Eureka

Slocan District, British Columbia.

and some 500 tons from the Hidden Treasure. This year's shipments from the former at the end of April amount to 1300 to 1400 tons. Operations on the Hidden Treasure are in the charge of Oscar V. White, of Sandon, resident superintendent for the Byron N. White Co. The chief interests in this company are held in Spokane, Washington, and Milwaukee, Wisconsin. The Ruth Mines, Ltd., is an English company, having as managing director and local manager, George Alexander, of Kaslo. The Ruth group comprises 14 mineral claims. The mine is opened by five tunnels and the underground development aggregates nearly 15,000 ft. The vein is opened to a vertical depth of 600 ft. The ore, which occurs in lenses and irregular bodies, is hand-picked, and that which is not of good enough grade for shipment is concentrated. It yields two products, silver-lead and zinc concentrates. The former averages 65% lead and 85 oz. silver per ton. The zinc concentrate as it leaves the mill averages about 36% zinc, 1.5 lead, 14 iron, and 12 oz. silver per ton. At the Kootenay Ore Co.'s sampling works, at Kaslo, it is passed through Dings electro-magnetic separators and raised to a 50% zinc content. In 1908 the Ruth shipped 750 tons of hard ore and carbonates and 1257 tons of zinc concentrate. The Rambler-Cariboo output last year, about 1200 tons, was not large, owing to low prices of silver and lead. This year a production of about 100 tons per month is being maintained. The ore averages about

116 oz. silver per ton, 46% lead, and 12 zinc. A deep-level tunnel, 4500 ft. in length, is at its face 1450 ft. below the lowest outcrop of the vein, and 2400 ft. below the apex outcrop on the summit of the mountain into which it has been driven. This drains the mine and admits of exploration below the level of the old workings. Last year two new orebodies were found, the deepest being on the 1050-ft. level. W. E. Zwicky, of Kaslo, B. C., is manager. The controlling stock interest in the Rambler-Cariboo Mines, Ltd., is held in Spokane, Washington, where the company's head office is situated. The Lucky Jim, which in recent years has not been operated, is to be worked under lease. It is situated on the Kaslo & Slocan railroad between Kaslo and Sandon. The lessees are Hemenway & Loper. G. W. Loper has lately been making arrangements at Kaslo for the shipment of ore by steamer down Kootenay lake to a point on the Great Northern railway between Nelson and Spokane, Washington. The Lucky Jim vein was discovered in 1892, and was worked irregularly for silver-lead for several years. During the years 1896-99 about 5600 tons of concentrating ore was produced, and from this was sorted out 1600 tons of zinc blende averaging 50% zinc, 3% lead, and 6 oz. silver per ton. After having been idle several years the mine was re-opened in 1903 by George W. Hughes, its present owner, and worked for three years, during which time about 6000 tons of zinc blende averaging 54% zinc was mined. The collection of duty on zinc ore entering the United States resulted in stopping operations in 1906. It is stated that the zinc zone has been passed through in the mine, and a body of silver-lead ore entered, which later promises a considerable tonnage of ore of shipping grade. The Whitewater and the Whitewater Deep have been for about two years worked under lease by S. S. Fowler, of Riondel, W. E. Koch, of Nelson, and John L. Retallack, of Kaslo, all of whom have long been actively associated with mining in the district. Mr. Retallack is in charge as manager. Production in 1908 amounted to about 30,000 tons of ore mined and milled, and shipments were 2300 tons of silver-lead concentrate averaging 120 oz. silver per ton and 45% lead, and about 8000 tons of zinc running 40 to 45% zinc with 20 oz. silver per ton. A new company, named the Deep Mine, Ltd., has been incorporated and has taken over part of the property. This company is also managed by Mr. Retallack. It is driving a 1500-ft. tunnel to develop the property.

BUTTE, MONTANA.

Smoke Damage.—Corbin Copper.—Tuolumne.—Pittsburg-Montana.—East Butte.—April Production.—Parrot.

The final complaint of the farmers of the Deer Lodge valley concerning smelter fume has been disposed of. Judge Hunt asked them to show by what means the smelter fumes can be reduced; the smelter officers have claimed that everything known to science had been done. The farmers claimed that the company had not sincerely tried to abolish the smoke nuisance. They presented a plea to Judge Hunt affirming that they could not secure the services of expert witnesses "except under very unsatisfactory assurances." They proposed that the whole question of damages be submitted to arbitration, and if the board should find unfavorably to the Amalgamated Co. that the company be required to condemn the land owned by the farmers. The attorneys for the Amalgamated Co. objected, claiming that the matter of damages had been passed on by both the master in chancery and by Judge Hunt, both of whom had decided against the farmers. Judge Hunt took the matter under advisement. Two experts representing the Federal Government have been making tests at the Washoe smelter with a view to determine whether or not the objectionable substance in the smoke could be converted profitably into sulphuric acid and fertilizer. They are being given every assistance by the Washoe officials. The latter have always contended that it would be impracticable to manufacture sulphuric acid, as the smelter could turn out 2400 tons per day, which is more than the entire world uses. To manu-

racture fertilizer it would be necessary to haul phosphates several hundred miles to the smelter, and the product would soon glut the market, there being little demand for the fertilizer in the West. To turn the sulphuric acid into the streams would cause more damage than to let the poison disseminate in the atmosphere. A former government expert suggested a pipe-line to the Pacific ocean, but this was shown to be impracticable. The case was dismissed.

The Corbin Copper Co., which is developing a group of 30 claims in the Wickes district, has cut the main lead in three places. Last week the Dewey tunnel cut the lead and found 25 ft. of ore, some of which assays 5% copper. Drifting is now being done on the vein. A good lead has also been cut in the Kathleen tunnel. The property is in condition now to yield ore for regular shipment, but no mining will be done for some time yet. The Tuolumne Copper M. Co. has just installed its new hoisting engine, a Nordberg first-motion, capable of working to a depth of 3000 ft. A new 20-drill compressor and additional boilers have also been erected. The company is now sinking a sump below the 1400-ft. point in the shaft, and when this is completed will cut stations at the 1400 and 1200-ft. levels, preparatory to cross-cutting to the vein south of the shaft. There is good ore in the veins at 1000 ft., but not sufficient in quantity. There are three veins that apex in Tuolumne group. The middle vein is the extension of the Edith May of the North Butte Co., and is the first vein south of the shaft.

In the consolidation of the East Butte Copper Mining Co. and the Pittsburg & Montana Copper Co., an important copper-producing company is formed. The East Butte Co., according to a call for the special meeting which is to be held May 11, will increase its capital stock from 300,000 shares to 600,000 shares of the par value of \$10 per share, the increase to be used in taking up \$2,500,000 in Pittsburg & Montana bonds and about 83% of that company's stock, on which the East Butte directors have secured an option. Three of the Pittsburg company's directors will be added to the board of the East Butte Co., and Oscar Rohn, who as superintendent has brought the Pittsburg company to a profit earning basis, will remain in charge of the operations of that company.

April copper production by the Butte companies aggregated 25,347,420 lb., the mines averaging about 28 working days in the month. Not so much decrease in the month's output as had been anticipated. The ore tonnage was reduced, a higher grade being shipped to the smelters, but the curtailment of the copper production was not more than two million pounds.

Companies.	Output, lb.
Boston & Montana	7,350,000
Anaconda	6,451,200
Butte & Boston	1,128,960
Washoe	905,240
Parrot	649,600
Trenton	718,620
North Butte	3,339,000
Butte Coalition	2,912,000
Original	1,064,000
Pittsburg & Montana.....	604,800
Miscellaneous	224,000
Totals	25,347,420

The total average daily production was 905,265 lb., and there were 353,640 tons of ore mined during the month.

The Parrot Mining Co. is developing the Parrot vein on two levels, known as the 1900 and 2000-ft. levels, and on both the results are increasingly satisfactory; ore running 3 to 4% in copper having been found. At the Little Mina the company is engaged in cross-cutting for the vein. The stockholders of the Butte-Balaklava Co. have been invited to subscribe to a new issue of treasury stock at \$10 per share. The cost of copper made by the North Butte Mining Co. is around 8½ cents per pound, according to one of the officials of that company. It is also asserted that the mine is in as good condition as at any time, and that developments on the new levels are satisfactory.

WASHINGTON.

Progress with the Tariff.—Reservoir Sites.—Irrigation.

Although a determined effort is being made to pass the tariff bill as framed in the Senate and presented by N. W. Aldrich, senator from Rhode Island, strong opposition has arisen to a number of important schedules, including all those relating to the mineral industry, and as the bill is being read in committee of the whole, all these paragraphs are being laid aside at the suggestion of certain senators until the undisputed paragraphs in the bill are disposed of. The senators who requested that the items go over are busy preparing amendments which will be more satisfactory to their constituents. There will be amendments to the iron-ore schedule, oil, zinc and lead ores, and coal. In compliance with an act passed March 3, 1909, which authorizes the Secretary of the Interior to reserve all lands within the Flathead Indian Reservation of Montana valuable chiefly for reservoir sites, and to report to Congress such reservations, Mr. Ballinger has sent a communication describing the lands within the reservation which have been reserved for the purposes mentioned.

Simon Guggenheim, senator from Colorado, has presented a bill which seeks to encourage irrigation. It provides that any citizen who shall sink a well so as to secure a flow of water adequate to irrigate at least 10 acres of land on any quarter section of any of the public lands of the United States within the States of California, Colorado, Idaho, Montana, Nevada, North Dakota, Oregon, South Dakota, Washington, and Wyoming and the Territories of Arizona and New Mexico, shall be entitled to a patent for the whole of the quarter section. C. B. Slemm, of Big Stone Gap, Virginia, representative in Congress, has introduced a bill which provides that \$2,000,000 of the money that would otherwise become a part of the reclamation fund be used for the drainage of certain lands in Virginia. The American Physical Society, composed of the foremost instructors of the leading universities of the United States and scientists prominent in the government service were the guests of the Washington Philosophical Society this week. A feature of the session was a lecture by Professor Max Planck, of Berlin University, on 'Mechanics as the Foundation for Physics.'

LONDON.

Exposition of Cornish Mining —Metallurgical Instruction in London and at Sheffield.—West Australian Mining Costs.

Visitors to London this summer will have the opportunity of studying Cornish mining at the White City, or Imperial International Exhibition, at Shepherds Bush. Last year at the same exhibition there were many mineral exhibits showing the resources of the English Colonies, but they were scattered and not particularly useful or interesting to the mining man. This year the Cornish exhibit will be especially attractive. It is being organized by George T. Holloway, R. Arthur Thomas, of Dolcoath, J. J. Beringer, principal of the Camborne School of Mines, J. B. Cornish, secretary of the Geological Society of Cornwall, and many others of similar standing. For president of the section, Lord Falmouth has been chosen. Lord Clifton, Mr. Basset, and Mr. Pendarves have been elected vice-presidents. The exhibition will include almost everything dealing with the history and present position of the tin and china-clay industries, and with such a strong backing is sure to be exceptionally complete.

The evolution of the Imperial College of Science and Technology at South Kensington, which swallowed up the Royal School of Mines, at least in organization if not in name, is proceeding steadily if slowly. The latest arrangement is in connection for advanced studies in the metallurgy of iron and steel. It has always been felt that the provision of special laboratories and works at South Kensington for the study of this branch of metallurgy would be a mistake. Sheffield University already has as perfect a steel course of study as could be evolved, and it is desirable to specialize in London on non-ferrous ores. An admirable

arrangement has just been made whereby the metallurgical department at Sheffield will be affiliated with the Imperial College so that such students as desire to study iron and steel may take the special courses at Sheffield. The plan is for the two colleges to exchange facilities for study. Similar arrangements are said to be contemplated in connection with the iron and other metal courses at Birmingham and with the coal mining courses at Birmingham or Newcastle-on-Tyne. It is too early to give details at present. The steel course at Sheffield under the direction of Professor J. O. Arnold has won a very high reputation.

The reports issued by the West Australian mining companies are models of their kind and are therefore always worth close study. If every gold mining company provided such details it would be all the better for business. I specially say gold mining companies, because we can hardly expect companies producing copper and other metals, the markets and prices for which vary, to furnish the same details. The report of the Ivanhoe for 1908 has just been published. One of the most interesting items disclosed is that the working costs have now practically arrived at a minimum, being 17s. 8d. per ton of 2000 lb., as compared with 17s. 10d.

tons with an average content of 49s. 8d. These at the present rate of extraction should yield 43s. per ton, which is not much less than the yield for 1908. These reserves amount to rather over four years' supply, and developments have been such that the available tonnage has remained practically constant for several years.

SALT LAKE, UTAH.

Floods in the Desert.—Tintic Smelter.—Boston Con. Mill.—Mason Valley Smelter.—Cactus.—Silver King Coalition.

Melting snows have raised the level of the lake to such an extent as to cause uneasiness at the Garfield smelter. The Western Pacific tracks were under water, and except for the fortunate interposition of cold weather serious flood conditions would prevail.

The Tintic Smelting Co. is running with one copper and three lead furnaces in blast. Since October 29 over 6000 tons of bullion have been shipped by this company. The engineers of the Cole-Ryan syndicate, however, failed to recommend the purchase of the plant.

Garfield Smelter, Utah.

during 1907. It is possible that but for a strike of firewood cutters in July, which caused the closing down of the mine and mill for a week, the average costs over the year might have been even slightly lower. In 1904 the costs were 21s. 3d. and during the next two years they were reduced to 19s. 5d. and 18s. 10d. respectively. These working costs include only mining, reduction, and general expenditure at the mine, and not mine development, London expenses, or taxes. Including mine development and all other West Australian expenditure, the costs at the mine came to 20s. 10d. per ton during 1908, as compared with 22s. in 1907 and 24s. 2d. in 1906. The average grade of the ore has been gradually decreasing, the yield having been 43s. 11d. in 1908, 45s. 4d. in 1907, and 50s. 3d. in 1906. It will thus be seen that the average profit has not been greatly reduced, having been 23s. 3d. per ton in 1908, 23s. 6d. in 1907 and 26s. 1d. in 1906. During 1908 the ore crushed in the 100-stamp mill was 227,898 tons, and the yield from the mill and cyanide plant was 117,743 fine ounces realizing £502,294. The total output since the commencement in autumn of 1897 has been 1,193,302 fine ounces valued at £5,086,339, and the total dividends paid have amounted to £2,230,000. For the last five years the dividends have been regularly £240,000 per annum. Ore reserves continue to be developed and the figures at December 31 last were 931,989

At the Boston Con. mill there has been some trouble with breaking of cam-shafts. The difficulty is believed to have been due to the steel in the shafts being too highly carbonized. The trouble has been remedied. New shafts put in seven months ago have run without a break. The battery superstructure in the mill originally rested on centre jack posts, and additional braces have now been put in, making the construction rigid. The Nissen stamps are giving high duty, and have vindicated the choice of this method of crushing, made by A. J. Bettles, the superintendent of mills. The Utah Stock & Mining Exchange is about to move into new quarters in the Atlas block.

The Mason Valley smelting plant at Mason City, Nev., is not to be built at present. Some of the larger interests in the company object to building at a time when less than 1,000,000 tons of 4% copper ore is available. The surveying for the smelter-site has been completed, but no excavation work will be ordered until at least double the present tonnage is in sight. Of the authorized capitalization of 1,000,000 shares, 770,000 has been issued. George E. Gunn, general manager, is authority for the statement that a portion of the remaining 230,000 shares will be issued and sold to provide money needed to build the smelter. The plant is to do custom work for the Yerington district.

Since the closing down of the Cactus mine at Newhouse

little has been done toward overhauling the plant. A small force of men are at work underground prospecting. The higher-grade bodies of copper ore in this property have practically been exhausted. Until a better ore is found the prospects of resuming operations are not favorable. The company has outstanding obligations said to aggregate \$200,000. Samuel Newhouse has pledged himself personally for most of this indebtedness, and unless large bodies of commercial ores are soon found, the indications are that Mr. Newhouse will again have to raise money for the company. He is now in New York. Plans for the reorganization of the company, with the addition of the Fink Smelting Co., are said to be under consideration. The experimental Fink smelting plant has been giving a good account of itself for more than a week past. The loss now is less than 1%, but the cost of treatment is such that the device is not as yet practicable.

Since the entry of the International Smelting & Refining Co. into Utah, many rumors are afloat regarding properties to be acquired. In addition to invading the Tintic district, it is said that overtures have been made to them for the purchase of F. Augustus Heinze's holdings in the Silver King Coalition Mines Co. Thomas F. Cole has inspected the Coalition properties and knows something of the deposits. The Coalition company refused to allow Heinze to transfer his smelting contract to the International, but it is thought that if the International purchases Heinze's interest the Coalition company will consent to the transfer of the contract. It is understood modifications of this contract have been agreed on. Should this arrangement be perfected it will put an end to the long dispute between the Coalition and Heinze, and give that company an opportunity to double its present output.

Arrangements are to be completed for the sinking of a 2-compartment shaft at the Prince Consolidated properties in Pioche. When operations were first inaugurated at this property a slope was driven parallel to the vein. This is now 600 ft. deep. As the vein has straightened up, the shaft at the bottom is more than 200 ft. from the vein. The long drifts on the lower levels are expensive and the arrangement for handling the ore is interfering with development and ore extraction. The new shaft is to be sunk 1000 feet.

JOHANNESBURG, TRANSVAAL.

Company Meetings. — *Rand Mines, Ltd.—East Rand Proprietary.* —
Ore Reserves. — *Diamonds in German Southwestern Africa.*

For the majority of Rand mining companies, the financial year coincides with the calendar year. Numerous meetings annually occur in March and many reports are now, therefore, available. There are few engineers who have the leisure to wade through the reports in search of technical data. Broadly reviewed, the most satisfactory feature is the tone of cheerfulness and optimism consistently maintained. So many companies have been able to boast of bigger profits and improved efficiency that the chairmen of those concerns which have not done well have generally succeeded in presenting a hopeful outlook by reference to the success of their neighbors. At the meeting of the Rand Mines, Ltd., L. Meyersbach gave his usual review of the field's industrial progress, but the great improvement in the financial and technical position enabled him to speak "with more pleasure and confidence" than at any former period. The company's profit for 1908 totaled £1,010,830. Of this £853,079 was distributed to shareholders, bringing the dividend total to £4,092,815. Of the total revenue for the year (£1,047,088) £904,592 represented dividends from the 9 chief subsidiaries and from 3 other companies in which it holds large interests. Six of the company's subsidiaries increased their dividend rates during the year. Another meeting of great importance was that of the East Rand Proprietary. This has been the first ordinary meeting held since the amalgamation, which resulted in the unification of the group of mines formerly controlled by the company. During the last 6 months of the year, the company milled 856,320 tons with a profit of £591,744. The

yield per ton was 30s. 7.3d. per ton and the costs 16s. 9d. The technical records of the company show that the ore reserves have been greatly increased during the year. It is satisfactory to find, indeed, that the majority of Rand mining companies have been fully alive to the necessity of increased development to satisfy requirements of extended milling equipments. Summarizing the position of a few of the mines, whose meetings have been held lately, the following statement may be compiled:

Company.	Annual milling capacity, tons.	Payable ore developed, tons.
East Rand Prop.....	1,700,000	6,347,430
Ferreira	300,000	1,317,565
Simmer Deep	540,000	747,000
New Kleinfontein	460,000	1,053,600
Robinson	520,000	4,644,000
Village Deep	430,000	1,949,267
New Primrose	237,000	475,900
Ginsberg	144,000	473,000

With one exception the ore reserves are estimated over assumed stoping widths. The Simmer Deep calculates on milling tons. The position of the Robinson is exceptional. Obviously it would not be good policy in the Central Rand to develop so far ahead of the mill and incur expenditure on which no return could be expected for several years. But the Robinson reserves include 1,856,000 tons of Main Reef (valued at 4.75 dwt. over a stoping width of 90 in.), which have been developed by the drifts originally intended to serve only the Main Reef leader. This enormous tonnage has thus been added to payable ore reserves without new expenditure, owing to the reduction of working costs (now 11s. 6d. per ton milled) and the consequent lowering of the limit of payability. For the Rand Mines, Ltd.'s nine producing subsidiaries, with an aggregate milling capacity of 3,250,000 tons per annum, the ore reserves amount to 10,700,000 tons.

At the meeting of the Voorspoed Diamond Mining Co. held last week, the chairman stated that the German Government had taken control of the diamond output from German Southwestern Africa and that nothing would be done to disturb the market by overproduction. Official estimates at one time ran up to an output of 5000 carats per day. Dr. Merensky and M. E. Frames visited Damaraland recently and have since discussed the origin and capabilities of the diamond field before the Geological Society of South Africa. The district is situated near Luederitz bay and presents a billowy surface, mostly sand-covered. It is practically rainless. The diamonds are won from the sand and are nearly all of small size, though a few weighing 3 and 4 carats have been found. The average value is about \$7.50 per carat. There is only a thickness of about 4 in. to the diamantiferous layer of sand, and it is estimated that only one-fifth of a carat is found per square yard. Dr. Merensky estimates that the total yield of the productive area can only be about 1½ million carats—an amount reckoned in Germany to be the annual yield for an indefinite period. The origin of the stones is a controversial matter. The two most widely accepted theories were (a) that the stones weathered out in the neighborhood of their present locality either from kimberlite, the older rocks, or amygdaloidal diabase; (b) that the diamonds were either transported from the interior by rivers or carried up from the south by the wind, or that the sea has washed them ashore in more recent times. Dr. Merensky and Mr. Frames, however, are unwilling to accept either view and consider that the diamonds were deposited contemporaneously with the sediments of the Cretaceous beds occurring thereabouts, which have been disintegrated and subject to natural concentration in the sandy valleys. They state that the typical kimberlite minerals have been proved to be absent. A few days after this paper was read a report reached Johannesburg that true yellow and 'blue ground'—the peridotite of Kimberley—had been struck by sinking 40 to 50 ft., and that, although no wash had yet been obtained, the familiar garnets, 'carbons' (ilmeneite), and mica were present.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Mullock is a West Australian term for waste rock.

Bridge members built up of structural steel have approximately half the strength of the component metal.

Magnesite sells in San Francisco at \$6 per ton. It is used by paper-makers and manufacturers of mineral water.

Petroleum from the Caddo, Louisiana, field runs 21.3 to 41° B. It is mostly a black heavy oil with a paraffine base, and contains as much as 1% of asphalt.

Allowance for impact stresses is made in designing bridges, but where electric motors in place of reciprocating engines are used these stresses are small.

High volatile content in coal reduces the relative heating capacity, which is the same as saying that the calorific power increases with the amount of fixed carbon present, the percentage of other constituents remaining unaltered.

Coal of 1.3 sp. gr. weighs 81.25 lb. per cu. ft., and a square mile of it, 1 ft. thick, contains 1,132,544 short tons. From this 25 to 50% must be deducted for waste in mining, and in addition whatever is indicated by the presence of faulting.

Under the doctrine of appropriation of water, he who is first in time is first in right, and as long as he continues to apply the water to a beneficial use, subsequent appropriators cannot deprive him of the rights his appropriation gives by diminishing the quantity or deteriorating the quality.

Shrinkage stoping is a term used in Western Australia for working stopes filled with broken ore. The term shrinkage refers to the fact that it is necessary to draw off about one third of the ore broken in order to give working room. The term 'filled stopes' is reserved for those into which waste rock has been run.

Scheelite is a common accompaniment of tin ores in Cornwall, England. It is usually associated also with copper in the same lodes, and tourmaline is generally present. This is also a combination frequently found in this country. While one may not be justified in the search for a certain metal when its ordinary accompaniments are discovered, it is always well to keep on the lookout for it. Tungsten-bearing metals with tourmaline have been found in many places in the granitic areas of the desert region of southern California.

Slickens is a term applied to slime of the kind which packs and will form a bottom in a running stream that will resist scour. The term slime has lost its original significance, which was practically that of 'slicken', or, more properly, particles of comminuted rock or ore in which one axis was extremely

small in comparison with the other dimensional axes. In modern parlance 'slime' has superseded 'fine', and means only finely comminuted ore. Hence 'slicken' is useful as a term. Slickens are usually highly argillaceous, sericitic, or talcose slimes.

Silver may be detected when present in so minute a quantity as 0.01 mg. in solution. The re-agents used are 20 gm. salicylic acid slightly over-neutralized with ammonia, diluted to 1 litre, and a solution containing 50 gm. ammonium persulphate per litre. To the solution suspected of containing silver is added 20 c.c. of the salicylate solution, followed by 20 c.c. of the persulphate solution. An intense brown coloration is produced in the cold. It should be noted that this is evidently a catalytic action, as the same coloration is produced by boiling the solutions when silver is not present.

Magistral is not necessarily bluestone or copper sulphate. In the patio process time is counted upon to make up for defective materials, and in the early days the copper ores were merely given an imperfect roast, ground in arrastres or in Chilean mills, and mixed with *lama* or slime for addition to the pulverized ore in the *torta*. The sulphate of copper was thus mainly produced from the partly oxidized sulphides by further reactions in the *torta* or cake, that being the name given to the mass of pulverized ore which, like a thick mud, was spread out approximately 18 in. thick in the patio. Mines which produced copper ore suitable for making this desirable material were often called by the name *magistral*, which at once indicates its character.

The junior location with an end line A B C, as shown in the accompanying cut, is a valid location, though there is grave question whether a location with a broken end line, like this, would confer extralateral rights. The proper way to lay out the boundaries of the junior claim would be to extend B C to X and establish this as one of the corners of the claim. This course is authorized by the U. S. Supreme

Court in the Del Monte case. The junior locator would not, of course, acquire any surface rights to the triangle A B X. The extra-lateral rights of the senior location, assuming that the lode is the discovery vein, would be determined by the perpendicular planes B G and F H. The junior location would be entitled to all of the vein on its dip between the perpendicular plane D M and C' N, after subtracting the extra-lateral rights of the senior location.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Designing Mine Equipment.

The Editor:

Sir—During the ten years I have been connected with the Arthur Koppel Co. I have had the opportunity of meeting the most prominent men in the mining industry, both in the United States and abroad, and of noticing their differences in methods of ordering machinery. In America, when a mine is in need of machinery, generally the chief engineer and the superintendent meet to discuss the matter. They usually decide that the machinery must be installed in the shortest possible time. At a second meeting, the superintendent calls attention to some practical points which should be taken into consideration. The engineering force then goes to work, and after a few weeks the plans are ready. Several blue-prints are made and inquiries sent out to manufacturers.

Not quite a year ago, while traveling in Europe, I took occasion to call on an old friend, well known in mining circles. He had just received a couple of hundred steel mining cars from one of our European branches, and had dictated a letter to our manager expressing his satisfaction. I asked him if the cars were of his own design, and he said in a kind of reproachful tone, "No, old boy, I gave up designing machinery myself long ago. It is not my business, and you fellows are in better shape to do it than I. Of course, I suggested certain changes, but as a whole the design is yours." In fact, abroad, the chief engineer or superintendent seldom designs any machinery. Generally when new equipment has to be installed, they write to the manufacturers, telling them their needs, explaining in detail the purposes of the new equipment, and in what way it will have to be used or operated. Which plan is the better is open to difference of opinion, but I personally believe it is better to leave the general designing to the maker of the machines.

A manufacturer receiving a drawing from a buyer has to make his figures exactly as per this drawing; very often where an improvement could be made, he refrains from making suggestions because he does not want to offend the chief engineer who designed the equipment. Furthermore, the factory can not be made responsible for failure if the work has been executed in accordance with the drawings and specifications. I know of one case where a suggestion was made looking toward improvement, and the engineer said he knew all about his business and did not want anybody to tell him how to construct machinery. The construction proposed by the engineer may involve certain steel bars bent in such a way as to make the labor unnecessarily expensive. This the manufacturer only can judge. The engineer of the mining company may have designed a special casting, when the manufacturer has similar patterns in stock

which could be substituted. Now, if he has to stick to the plan of the engineer of the mine, he must naturally consider the cost of the new patterns. He finally might have a certain kind of material more suitable than the one specified, or he could use a certain size of steel bar he has in stock without making it necessary to wait for the delivery. There are many similar points which could be enumerated.

In the case of mine-cars, for example, the specialist who is designing practically nothing but cars constantly improves each part. He has information about all the inventions and improvements in his special line, and must naturally know more about it than the chief engineer of a mine, who only orders steel cars once a year or so. When the mining engineer designs the cars, the mining company loses time, spends more money than necessary, and takes the risk of receiving something antiquated.

I certainly believe that the mining engineer or superintendent who asks the representative of a manufacturing firm to make suggestions about the machinery he wants to buy, and who gives him all the details as to his needs, but asks him to make up the design, saves by doing so, and the chances are that he will finally receive a more perfect piece of machinery than he himself could design.

After the first sketch has been received the mine manager will be able to judge whether or not the manufacturer is the right man to deal with. The design submitted must absolutely cover the needs of the consumer; if it does not, the representative did not understand the needs of the mine, and where such a representative is sent by a manufacturing concern, the chief engineer of the mine is entitled to conclude that he could not do business satisfactorily with the particular manufacturer. A few corrections will always have to be made to meet the individual conditions of the mine. I have seen money spent in similar cases which could have been easily saved, if instead of proceeding on the assumption of 'knowing all about it', the specialist had been consulted.

P. SCHIBER.

San Francisco, April 5.

Mining in Siberia.

The Editor:

Sir: The article on 'Mining in Siberia', in the MINING AND SCIENTIFIC PRESS of February 13, recalls the years 1903, '04, and '05, which I spent in the region adjacent to Vladivostok and in eastern Manchuria. The mine on Askold island he mentions was discovered some thirteen years ago, through pieces of float being picked up when the present lighthouse was being built. The Chinese had worked the gulches for placer gold below the present mine for some time previous. The contractors for the lighthouse, O. W. Lindholm & Co., took interest in the rich float and located along the outcrop of what was then supposed to be a large and exceptionally rich vein. Shortly after they had started open-cutting in the decomposed outcrop they were offered for their holdings a large sum by a French company, but Lindholm, who had been in Grass Valley, California, about

1860, and had seen a real quartz mine, refused to sell. The present mill was ordered, consisting of five 350-lb. stamps and two Johnston concentrators. A Californian was sent out to set up and run the mill, and the property did well from the start. This was about 1900, and the mill was the first one in eastern Siberia, and, as far as I know, is the only stamp-mill there now. Shortly after this a 5-ft. Bryan mill was bought, but by the time the soft top of the vein was well worked out and its real size acknowledged, the problem of getting out ore enough to feed both mills was too much to handle. The Bryan mill was moved over to the mainland, near Nahodka bay, a part of America bay, which is about 100 miles north of Vladivostok.

After a year or two, during which the mill was operated in the open season, the cost of good American supervision, the inefficient local labor, and the peculiar Russian laws, made a change necessary. A contract was therefore made with some Chinese, whereby they mined the ore for half the bullion, the mill being only run during the warm months. As far as I know, the same plan is in operation now. The mill produced from two to five poods of gold per season, and the Chinese laborers probably stole much rich ore. However, despite all the leakage, the property has been a good investment for the owners.

I was in the employ of this company for about two years, and was principally engaged on the mainland in prospecting and developing several gold claims, and, during the war, some coal lands near Vladivostok. I did not have much to do with Askold till the summer of 1904, when I made two trips there. The vein is a small one, from 1 in. to 1 ft. wide, but exceptionally persistent for about 1000 ft., and at that time had been worked to about 500 ft. below the apex. The dip is practically vertical and the walls are granitic. The vein had numerous spurs and branches, but the main vein could always be followed. It always carried gold, generally most where it was narrowest. At the bottom of the workings the ore carried a large percentage of iron and copper pyrite and less free gold than above. Some of the ore was exceptionally rich, and it all averaged well. I have seen some beautiful specimens, but the Chinese probably saw many more. The method of work had always been to run a series of tunnels, one about 10 or 15 ft. above the other, which, from the Chinese point of view, was quite satisfactory. I tried to introduce a better system, but it only lasted while I was there to watch it.

Owing to the ignorant and careless Russian employees, the milling was very bad. I did fairly well with the mill when I was there, but the improvement was only temporary, and I had more important work elsewhere. The concentrate from most of the upper workings was rich, and amenable to cyanide treatment, but I had no opportunity of doing anything with it except in the laboratory. The method of letting the concentrate oxidize, and then re-milling, saved over half the gold content, but in the end it slimed so that a good portion was lost. From what I have heard, the mine was not doing so well last year.

At Nahodka bay I operated the Bryan mill for a time on a small vein that paid well. I also opened up

several promising quartz prospects. I examined quite a number of various prospects farther up the coast, as far as 100 miles north of Olga bay. On the Chuchiga river, above Olga bay, is a silver-lead prospect owned in Vladivostok that was formerly worked by Chinese and Koreans. Calamine is also found with the ore. A. Bordeaux examined the property. Near Olga bay is coal and some good magnetic iron, but how extensive the deposit is I do not know.

The coast country is an ideal one to be in—clear rivers, good hills, abundance of game and trout, timber, and plenty of Chinese farmers to rely upon for supplies and animals. From what I saw of the country, it has considerable undeveloped mineral wealth. Nearly all the streams have been worked for placer gold by the natives in former times, especially in the vicinity of America bay. Trees growing in the old pits were from 150 to 200 years old. All over northern China, Manchuria, Korea, and eastern Siberia there are similar workings, and these are fairly safe guides. The placers are generally exhausted, and no veins were worked except they contained good quantities of gold. Personally, I have a strong belief in Siberia for mining, especially where Chinese can be used as labor, as they are hard to beat when one understands them. The most of the working class that I had to do with were a worthless lot. However, I was there in a strenuous time and had principally to deal with convicts.

F. L. COLE.

Tientsin, China, March 16.

Unwatering an Old Mine.

The Editor:

Sir—I am studying the problem of unwatering a mine on the Mother Lode which has been shut down since 1882. The 300, 100, and 1500-ft. shafts are full of water and are caved near the surface. They are 4 by 9 ft. When the mine was running the water was baled by a skip from the 1500 to 1000-ft. level, and flowed along this for 740 ft. to the 1000-ft. shaft, up which it was raised by a Cornish pump. The shafts are inclines with a pitch of 70 degrees. The 1500-ft. shaft has a pent-house at the 900-ft. level, and also has several bends.

Electric power is available (11,000 volts, alternating, three-phase) at a cost of \$5 monthly. The mine is eight miles from the railroad. Freight from San Francisco is \$8 per ton.

No records are available as to the flow of water or to the amount of water in the mine. A former foreman guessed the flow at 25 gal. per minute. Another hint as to the amount of water is given by the time it took the mine to fill up, namely, two years. Unfortunately, there are no maps of the underground workings. It is known that levels were run every hundred feet below the 500, down to the 1000-ft., and extensive stoping was done. There are no levels below the 1000.

There is no machinery on the mine, and the problem is: What kind of machinery to be put on for the purpose of unwatering the mine. Shall I use electric pumps, and a hoist to handle them? Or shall I bale the mine out with a hoist and tanks? Can the air-

lift be profitably used? I am told that electric sinking-pumps are troublesome.

If any of your readers have been doing similar work lately, a record of their experience would be gratefully accepted, and I feel sure would be of interest to many of your readers. I should be glad to have advice on the proper method of doing this work.

I find the following estimate in my notes:

Estimate of Cost of Unwatering a 1500-ft. Shaft in Guanajuato, 1905.

By Baling:

60 hp. electric hoist	\$ 4,000
Freight	250
60 hp. for 6 months	2,250
1500 ft. $\frac{3}{4}$ -in. wire rope	500
Erection	500
Pay roll for 6 months.....	3,000
Two water tanks.....	500
General expenses	1,500

\$12,500

By Pumping:

50-hp. electric pump	\$ 3,100
Duplicate parts	500
30-hp. hoist	1,500
1500 ft. 5-in. pipe	2,000
Erection	500
Freight	250
80 hp. for 6 months	3,000
Pay roll for 6 months.....	3,000
General expenses	1,500

\$15,350

PROBLEM.

San Francisco, April 28.

Uses of Aluminum.

The Editor:

Sir—In a recent issue of the MINING AND SCIENTIFIC PRESS, Bertram Hunt has a communication on the possibilities of aluminum as a precipitant in cyanide work, especially where the solution contains base metals, such as copper. About a year ago I made a few experiments with aluminum, the solution having been used in the treatment of an ore containing 7 lb. of copper per ton. By precipitating the lime from the solution, and making it alkaline with caustic soda, it was found possible to regenerate 2 lb. of cyanide for each pound of copper in solution, as Mr. Hunt says can be done, but the cost was quite prohibitive. I have not the notes at hand, but think it figured at 80c. per lb. of KCy, at the price of aluminum then obtaining. Electricity, and even zinc-shaving precipitation, gave so much better results, provided the solution was rightly handled, that the aluminum experiments were given up.

There is little literature on the subject of aluminum precipitation. I remember a chapter in Gage's book and, I think, one in Dr. Scheidel's, and I find a stray note or two in my scrap-book, but all seem unfavorable to its adoption. The necessity of using caustic soda in the place of lime is a great objection. Nevertheless, in a process that is developing so rapidly as cyanidation, it is quite unsafe to predict, and Mr. Hunt and other workers would do well to experiment further. It is granted that both zinc and elec-

tricity present difficulties, and now that aluminum promises to become relatively cheap, it is certainly worth investigating.

Cyanidation in Guanajuato.

The Editor:

Sir: In an article entitled 'Cyanidation of Parral Silver Ores', appearing in your issue of April 3, H. T. Willis gives a tabulation of milling costs at various plants in which he does this company an injustice by erroneously making its milling costs appear higher than those of any other company cited. By publishing the following figures you will set your readers right, and show that the Guanajuato district is doing good work, and that the milling costs at this company's plant, instead of being the highest, are as a matter of fact and record the lowest:

Milling and Cyaniding Costs at Guanajuato Con. Co.'s Plant.

(Costs are in U. S. Currency.)

Year.	Milling.	Cyaniding.	Total.
1907	\$0.61	\$1.83	\$2.44
1908	0.62	1.68	2.30

Anyone having particular reason for comparing these costs with countries other than Mexico should bear in mind that the above refer to dry metric tons.

C. V. R. COGSWELL.

Guanajuato, Mexico, April 26.

Short Zinc.

The Editor:

Sir—In your issue of April 3, F. L. Bosqui touches upon several interesting subjects in his letter on 'Short Zinc', and I trust you will be able to induce him to publish in full his information on those subjects. The iron in solution, which he speaks of as acting galvanically upon the zinc, causing brittleness and an abnormal consumption, must have been present as a ferro-cyanide compound, and I am surprised to hear that galvanic action took place between such a salt and metallic zinc. A different explanation of his phenomenon might be given if it were known how much free cyanide, alkali (NaOH or Ca(OH)₂), and precious metal was present in the solution being precipitated; also the percentage of ferro-cyanide compounds. Furthermore, was the precipitation taking place in steel or in wooden boxes? Large zinc-consumption occurs from other causes than galvanic action, one of which is an extremely rich solution. I have frequently had more than 60% of the zinc in the head compartment consumed in 24 hours when precipitating very rich silver solution, a great hole being left in the centre. I would like to hear the result of Mr. Bosqui's experience in the comparative effect upon precipitation in the use of steel and wooden precipitation-boxes. It would also be of interest if your other readers would contribute their experience on that subject. According to Mr. Bosqui, I take it, wood should be used in preference to steel as material for the construction of zinc-boxes.

H. T. WILLIS.

Parral, Mexico, April 14.

MINES AND PLANTS OF THE PITTSBURG SILVER PEAK.

Written for the MINING AND SCIENTIFIC PRESS
By HENRY HANSON.

The mines and plants of this company are situated at Blair, Silver Peak mining district, Esmeralda county, Nevada. The company at the beginning of the present operations constructed a standard-gauge

the tramway buckets, which have a capacity of 800 lb. The tramway was built by A. Leschen & Sons Co. It has a length of 14,000 ft., with a total fall of 1600 ft. The capacity at normal speed is 450 tons per 16 hours. The ore is delivered to the mill storage bin, where the buckets are dumped automatically into a receiving hopper, from which it is taken by a 24-in. Stevenson-Adamson conveyor running the entire length of the 4000-ton mill storage bin. This

Silver Peak Mill.

railroad 17½ miles long, connecting Blair with the Tonopah & Goldfield railroad. The district is one of the oldest in the State, and for the past forty years has produced a considerable amount of high-grade ore, which was hauled by wagon to the town of Silver Peak, where it was reduced in small plants. The mines had been almost idle several years, when the advent of the railroad and electric power line, resulting in cheaper milling, induced the present company, after the purchase of the Blair property and the consolidation of the Mohawk-Alpine group, to begin operations on a large scale. The mines are situated 2.7 miles from Blair. All machinery is electrically driven, power being furnished by the Nevada-California Power Co. The compressor-plant consists of one 8-drill 2-stage Ingersoll-Rand compressor and one 2-stage 25-drill Nordberg. The motor driving the latter machine is of the General Electric 2-speed type. The mines are provided with a complete machine shop and all modern conveniences.

The orebody dips about 30°. The ore is mined and trammed to large loading chutes, from which it is transported by electric motors to the crushing plant at the upper terminal of the tramway. The cars have a capacity of 3 tons each. They are built with rigid frames, and are dumped automatically. Two cars may be dumped at once. The tippie is actuated by compressed air, one cylinder throwing in the holding dogs, unlatching the side doors, and throwing the cars into dumping position. The crushing plant consists of one No. 6 and two No. 3 gyratory crushers. The ore is crushed in two stages to pass approximately a 1-in. ring. From the secondary crushing the ore is elevated and passes through the automatic sampling machines. The discard goes to the 400-ton tramway bin, where it is loaded automatically into

conveyor is provided with an automatic traction-dumper.

After thorough testing for a process suited to the ore, it was decided to use the Merrill system for the secondary treatment. The present mill-site was selected in order to obtain a gravity plant. Nothing was spared in the design, construction, and equipment to make the mill and its auxiliary departments

Mortar Foundations.

a model in every way. Steel and concrete were used in the mill construction. The machine shop is at Blair, and has an equipment of machines and tools heavy enough to do all mine, mill, and railway repairs. The wood-working department is also complete with necessary machinery.

In the store department is a full and complete line

of mine, mill, and railway supplies, and repair parts, machine extras, and so forth.

The 100-stamp mill is of the usual type, containing, with 1050-lb. stamps, driven in units of 20 stamps each, by five 50-hp. Bullock motors. The stamps drop 96 times per minute, with a fall of $6\frac{1}{2}$ to $7\frac{1}{2}$ inches. The mortars are of special design, having massive bases with large area and are held in place by means of 8 foundation bolts. The manner of installation is shown in the illustration. The heavy reinforced concrete foundation is provided with a 6-in. built-up maple coping, surfaced perfectly true and laid up in tar. This coping is carefully cemented in place and provided with heavy rubber blankets between its top and the base of the mortar. The large cast-iron pedestal bases which receive the battery posts are also mounted upon the maple coping. The bottom of the mortar-bolts has the bolts enlarged with a keyway $\frac{9}{16}$ in. wide, which receives the gib-key as indicated. This gib-key engages the foundation washer as shown. Placed in the foundations so as to secure clearance in case it is necessary to remove the bolts, are pieces of 3-in. pipe. This type of construction has given excellent satisfaction, diminishing the usual failures of battery parts due to crystallization, which is invariably the case where mortars are mounted directly on a concrete foundation. The duty of the stamps, while it varies somewhat with the ore, will average 4 tons per stamp in 24 hours through a 35-mesh screen. The drop of the stamps, originally 105 per minute, with a $6\frac{1}{2}$ to $7\frac{1}{2}$ -in. fall, was reduced to 96 per minute, the fall remaining the same. This change reduced both the repair and power cost, and did not reduce the tonnage. That there should be no decrease in tonnage on reducing the number of blows of each stamp over 8% can only be accounted for by the fact that there was not sufficient time intervening between the rapid blows to allow sufficient ore to lodge on the die to gain the maximum efficiency from each blow. Crushing is done with 5 to 6 parts of water to 1 of ore. Outside amalgamation is used. The plates have an area of 12.8 sq. ft. per stamp, and are set on a grade of $1\frac{1}{4}$ in. to the foot. The water supply is pumped from Silver Peak through 17,000 ft. of 6-in. standard pipe, against 550-ft. head, to a steel storage-tank 30 by 22 ft. deep placed behind the mill at an elevation of 40 ft. above the battery floor. For this service is used a heavy 7 by 12-in. Platte Iron Works single-action direct-connected triplex pump. Water in the battery tank, 20 by 16 ft. deep, is maintained at a constant level by a float-valve, operating automatically, and is supplied by the storage tank mentioned above, and also by overflow from clarifying and sand tanks. A third tank, 20 by 16 ft. deep, furnishes water for sluicing out sand and slime tailing, and is supplied by returning the clarified sluicing water from slime presses, as well as part of the water overflowing from the sand tanks while filling, and also the barren waste solutions.

The tailing, after passing the amalgamating plates, is conveyed to the distributing sump of the clarifying department in a wooden launder 12 in. wide by 8 deep, set with a grade of $1\frac{1}{8}$ in. per foot. The bot-

tom of the launder is covered with $\frac{1}{4}$ -in. steel plate. A tippie is employed in this launder, through which the tailing may be temporarily turned to waste when necessary. Before entering the distributing sump the tailing passes through a screen box fitted with $\frac{1}{2}$ -in. steel trommel plate perforated with 7-mm. holes. This screen removes all wooden chips and coarse rock due to breaks in battery screens. The distributing sump, 3 ft. diam. by 4 deep, with a baffle-board, has two adjustable gates, which provides an even pulp-feed to each of the two settling cones. These cones are 8 ft. diam, with the sides sloping at an angle of 50 degrees. The stream of pulp is fed to the centre of the cone through a sump 12 in. square projecting 12 in. below the water-level. To the apex of each of the settling cones is bolted a multiple outlet casting, tapped to take four $1\frac{1}{2}$ -in. pipes. Each of these pipes feeds one of the sizing cones. The sizing cones are 4 ft. 3 in. diam. at the point of overflow, and have sides sloping 70° . The pulp-feed is introduced at the centre of the cone through an enlarged elbow submerged below the water-level to prevent all agitation. The sizing cones are fitted with the Merrill patented hydraulic sizers, by means of which a rising stream of clear water is caused to meet the falling sand. The water, being supplied at a low pressure, enters in such a way that no eddies or cross currents are produced. A thorough sorting is thus effected, the slime passing upward and overflowing the lip of the cone, while the coarse and fine sand pass out at the bottom discharge. Both settling and sizing cones are fitted with lead leveling strips to insure a uniform peripheral overflow. Special cocks and nozzles fitted with chilled-iron bushings are used to regulate and equalize both the feed and discharge of the sizing cones. The mill tailing is thus divided into two products—slime, the combined settling and sizing-cone overflow, and sand, discharged from the bottom of the sizing cones. The following figures as to the sizing of these products may be of interest:

	On 60 mesh. %	On 100 mesh. %	On 200 mesh. %	Through 200 mesh. %
Mill tailing	22.98	23.55	13.33	40.12
Classified sand	29.86	32.68	24.09	13.37
Slime			1.46	98.54

The tailing before classification, as has already been said, contains from 5 to 6 parts of water to 1 of solid. The sand after classification contains from 3 to 4 parts of water to 1 of solid, and the slime from 14 to 16 parts.

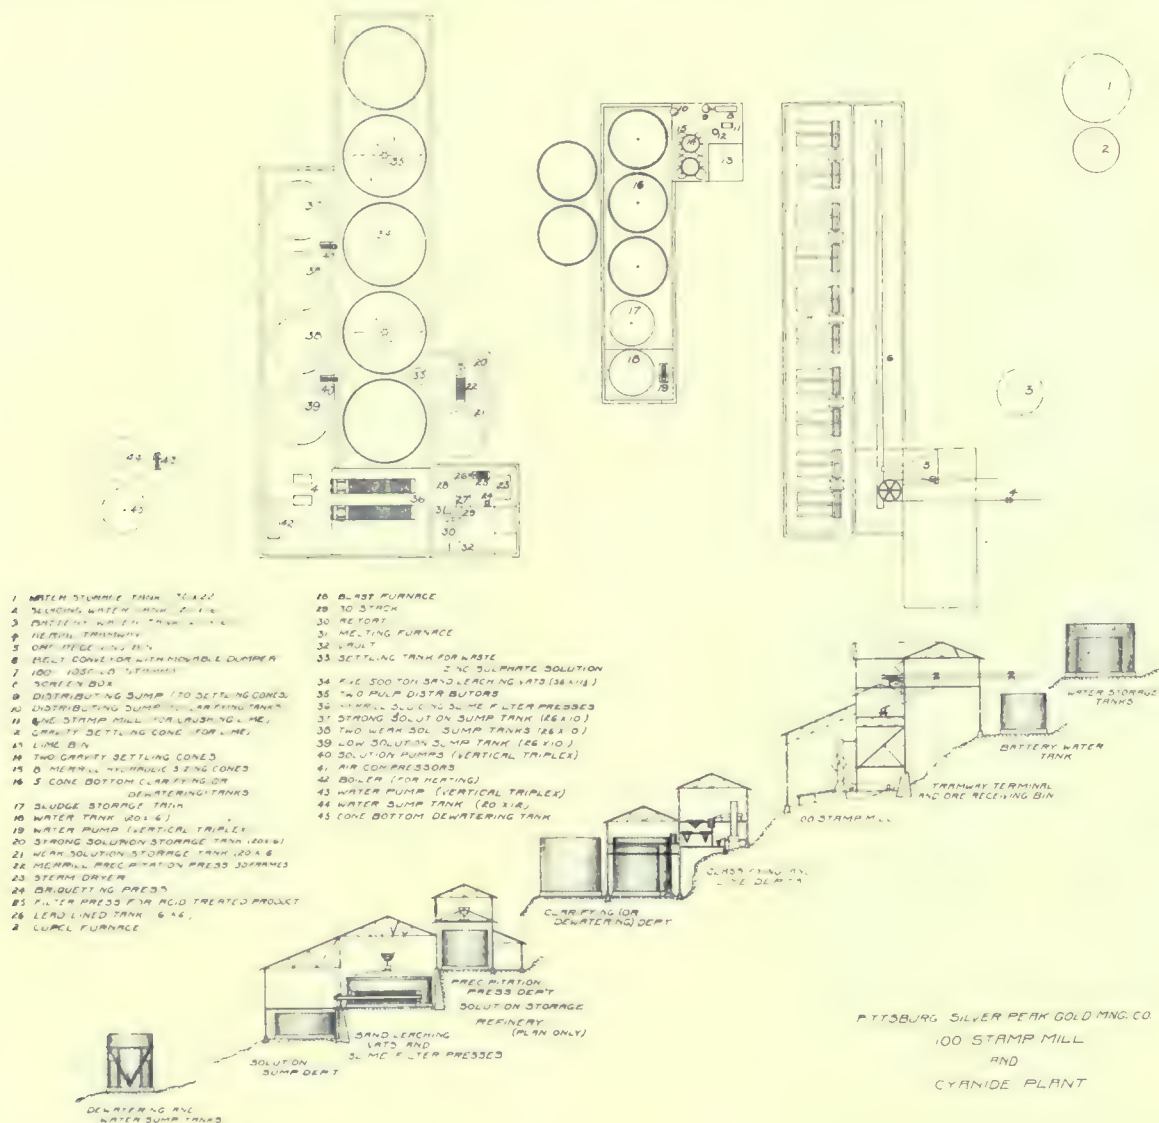

Lime is added to the sand in amounts varying from $2\frac{1}{2}$ to $3\frac{1}{2}$ lb. per ton. The lime is crushed wet in a 1-stamp battery through an 8-mesh screen. The manner of crushing causes the greater bulk of the lime to collect in unslaked granules, a fact that makes it possible to maintain a practically uniform protective alkalinity. The sand is then conveyed through wooden launders to the leaching tanks, where it is distributed by a mechanism of the garden-sprinkler type. These machines, two in number, are suspended from carriages on a track, and can be moved to any of the five leaching tanks. They were designed to insure an absolutely uniform distribution of the fine

and coarse sand throughout the charge, preventing all possibility of channeling during the subsequent direct treatment.

The leaching tanks, five in number, are 36 by 11½ ft. deep, and have annular launders to carry away overflow during the filling. The filter bottom consists of 2 by 4-in. pine placed on edge and spaced 2 in. apart, over which is spread a cocoa-matting and 8-oz. canvas filter. Each tank has a capacity of approximately 500 tons of sand, and under present conditions will fill in about 40 hours. When a tank has been filled, the drain valve at the bottom is opened, and the water in the saturated sand is allowed to drain. The drainage period requires about 14 hours, after

sand. The whole cycle of treatment from charging to discharging, at the present rate of filling, occupies a little over seven days.

The effluent solution from the sand charges is divided into three classes—'weak', 'strong', and 'low'. The 'weak' is the solution from the early periods of treatment, and flows to the weak or precipitating sumps, from which it is precipitated by being pumped through the precipitating press to the weak-solution storage-tank, thus becoming the barren precipitated solution which is used on the leaching tanks during the latter stages of treatment. The 'strong' solution is largely the effluent displaced by wash water, and flows to the strong-solution sump-tank.

which the treatment begins. This consists of alternating periods of air and solution, each air period being preceded by a drainage period. The unprecipitated standardized strong stock-solution is used during the earlier stage of the treatment. This is followed by a barren or precipitated weaker solution, which is in turn followed by wash water, used to displace the remaining gold-cyanide solution contained in the charge. The treated charge is then sluiced out through four side gates and one centre gate. One man with two 3-in. pipes with 1½-in. nozzles discharges a tank in about four hours. The water required for this purpose is approximately one ton to one of solid, including the water in the saturated

where it is standardized to the normal strength and pumped to the strong-solution storage-tank. The 'low' solution is the combined effluent from the first and final stages of treatment, low in cyanide, and kept at a sufficient tonnage to maintain the normal balance of solution in the plant. The sump tanks, four in number, one strong, one weak, and two low, are all 26 ft. diam. by 10 deep.

The combined overflow from the settling and sizing cones flows into a distributing sump with adjustable outlet gates similar to those mentioned in connection with the sand. From this sump five 'U' or round-bottomed galvanized-iron launders distribute the pulp to five clarifying or dewatering tanks. These
